Patents

This product may be protected by U.S. Patents 7,877,511; 7,958,347. This list is believed to be current as of September 24, 2012.

Export Regulation Notice

This product may include cryptographic software. Under the Export Administration Act, the United States government may consider it a criminal offense to export this product from the United States.

RF Interference Warning

This is a Class A product. In a domestic environment this product may cause radio interference, in which case the user may be required to take adequate measures.

FCC Compliance

This equipment has been tested and found to comply with the limits for a Class A digital device pursuant to Part 15 of FCC rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This unit generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference, in which case the user, at his own expense, will be required to take whatever measures may be required to correct the interference.

Any modifications to this device, unless expressly approved by the manufacturer, can void the user's authority to operate this equipment under part 15 of the FCC rules.

Canadian Regulatory Compliance

This Class A digital apparatus complies with Canadian ICES-003.

Standards Compliance

This product conforms to the IEC, European Union, ANSI/UL and Canadian CSA standards applicable to Information Technology products at the time of manufacture.

Acknowledgments

This product includes software from several third-party vendors. Each vendor is listed below with the applicable copyright.

Revision History

October 2005 - Rev A

March 2006 - Rev B, updates for Software Release 2.1.4

April 2006 - Rev C, Software Release 2.3

August 2006 - Rev D, updates for Software Release 2.4

September 2006 - Rev E, updates for Software Release 2.4.1

October 2006 - Rev F, updates for Software Release 2.4.2

January 2007 - Rev G, updates for Software Release 2.4.3

March 2007 - Rev H, updates for Software Release 2.5.0

May 2007 - Rev J, updates for Software Release 2.5.1

August 2007 - Rev K, add forest-to-forest trusts for Software Release 2.6.0

November 2007 - Rev L, minor output changes for Software Release 2.7.0

February 2008 - Rev M, minor show-policy changes for Software Release 2.7.1

March 2008 - Rev N, convert to F5 format; updates for Software Release 3.1.0

June 2008 - Rev P, updates for Software Release 3.2.0

June 2008 - Rev Q, updates for Software Release 4.0.0

July 2008 - Rev R, formatting change and minor updates for Software Release 4.0.1

September 2008 - Rev S, minor updates for Software Release 3.2.1

October 2008 - Rev T, CIFS features for Software Release 4.1.0
June 2009 - Rev U, updates for Software Release 5.00.000
November 2009 - Rev V, updates for Software Release 5.01.000
January 2010 - Rev W, changes for Release 5.01.000 update
March 2010 - Rev X, updates for Software Release 5.01.005
August 2010 - Rev Y, updates for Software Release 5.01.007
October 2010 - Rev Z, updates for Software Release 5.02.000
January 2011 - Rev AA, updates for Software Release 5.03.000
April 2011 - Rev AB, updates for Software Release 6.00.000
September 2011 - Rev AC, updates for Software Release 6.01.000
December 2011 - Rev AD, updates for Software Release 6.01.001
January 2012 - Rev AE, minor updates for Software Release 6.01.001, hot fix
April 2012 - Rev AF, updates for Software Release 6.02.000
October 2012 - Rev AG, updates for Software Release 6.03.000

Introduction

This manual is a reference for F5's Command Line Interface (CLI). The book is organized as a companion to the CLI user's guides (*ARX® CLI Network-Management Guide*, *ARX® CLI Storage-Management Guide*, and *ARX CLI Maintenance Guide*, in that order); for each chapter in the user guides there is a companion chapter in this book. This manual also has some additional chapters for CLI commands outside the scope of the user's guides.

The ARX

The Adaptive Resource Switch (ARX[®]) is a highly available and scalable solution that brings resource awareness to a file storage infrastructure, and adapts these resources to meet the demands of users and applications in real time. The ARX provides a file-virtualization layer that aggregates the total capacity and performance of your file storage. A *namespace* provides location-independent, transparent mapping of user requests onto the appropriate storage resource. You can configure policies that the switch enforces for the placement, replication and migration of files. Through policy configuration, the ARX adapts to the real-time demands of users and applications. The ARX thereby serves as a *resource proxy* for the files and services behind it.

Back-end Storage and Servers

The Adaptive Resource Switch aggregates heterogeneous file systems and storage into a unified pool of file storage resources. Through this unification, you can manage these resources to adapt to user demands and client applications. File storage assets can be differentiated based on user-defined attributes, enabling a class-of-storage model. You can reclaim stranded capacity through policy implementation for more effective storage utilization, and you can add capacity without disruption. Back-end resources are monitored for availability and performance, as well as user-access patterns that drive policy decisions.

Front-end Services

The Adaptive Resource Switch acts as an in-band file proxy for the Network File System (NFS) and Microsoft's Common Internet File System (CIFS) protocols.

Front-end services provide the file virtualization layer that masks the physical file storage from the user and application. The switch becomes the file access point, as opposed to the actual physical resource, providing file access through a *namespace*. Users and applications maintain a single consistent file path that is transparently mapped to the proper physical resource where the information resides.

Policy

The Adaptive Resource Switch provides policy-based resource switching. Through *policy* configuration, you can optimize the placement of files onto the appropriate storage resources and automatically adapt these resources based on user and application demand. The ARX performs file replication and migration based on performance, usage or other life-cycle characteristics, enabling you to implement a flexible file services strategy.

Examples of policies include: migrating files to reclaim stranded capacity; migrating files across different tiers of storage based on access patterns and/or value; and replicating frequently accessed files for performance. The result is more efficient utilization and greater flexibility in file storage management.

Resilient Overlay Network (RON)

You can connect multiple ARXes with a Resilient Overlay Network (RON), which can reside on top of any IP network. This provides a network for distributing and accessing file storage. ARXes can replicate storage to other switches in the same RON, updating the replicas periodically as the writable master files change. This is called a *shadow copy*, where a source volume on one switch periodically copies its files to one or more *shadow volumes* on other switches. Clients can access the shadow volumes at multiple geographic locations, independent to where the source volume resides.

Audience for this Manual

This manual is intended for

- network technicians responsible for layer 1 and 2 networks,
- network engineers responsible for the Internet Protocol (IP) layer (layer 3),
- storage engineers who design and manage storage systems (SANs, NASes, and DASes), and
- crypto officers who manage all of the Critical Security Parameters (CSPs) of a network.

The text presumes that all readers are comfortable with a command-line interface (CLI), especially one based on the Cisco IOS.

CLI Overview

The Command-Line Interface (CLI) has its commands grouped into modes. Modes are structured as a tree with a single root, *exec* mode. This section summarizes the mode structure and explains some CLI conventions.

Exec Mode

When you log into the CLI, you begin in exec mode. If the hostname is “bstnA,” the prompt appears as shown below:
bstnA>

You can access all global commands (such as show commands) from exec mode, and you can use the `enable` command to enter priv-exec mode.
bstnA> **enable**

Global Commands

You can access global commands from any mode, not just exec. Global commands include all show commands and terminal-control commands.

Priv-exec Mode

Priv-exec mode has the following prompt:
bstnA#

Priv-exec mode contains chassis-management commands, clock commands, and other commands that require privileges but do not change the network or storage configuration.

Priv-exec has two sub modes, `cfg` and `gbl`.

Cfg Mode

To enter `cfg` mode, use the `config` command:

```
bstnA# config  
bstnA(cfg)#
```

Config mode contains all modes and commands for changing the configuration of the local switch, such as network configuration.

Gbl Mode

To enter `gbl` mode, use the `global` command:

```
bstnA# global  
bstnA(gbl)#
```

Gbl mode controls all parameters that are shared in a redundant pair, such as namespaces and global servers.

Exiting a Mode

From any mode, use the `exit` command to return to its parent mode. From `priv-exec` mode, this command exits the CLI; to go from `priv-exec` mode back to `exec` mode, use the `no enable` command.

From any submode of `cfg` or `gbl` mode, you can return immediately to `priv-exec` mode by using the `end` command or pressing `<Ctrl-z>`.

Prompts

Prompts contain information about your position in the mode hierarchy as well as the name of the object you are configuring. For example, suppose you use the following command in `gbl` mode:

```
bstnA(gbl)# namespace wwmed
bstnA(gbl-ns[wwmed])#
```

This command places you into a new mode, as indicated by the new CLI prompt. The prompt shows the name of the mode, “`gbl-ns`,” and the name of the configuration object, a namespace called “`wwmed`.” Abbreviations are used for mode names (for example, “`ns`” instead of “`namespace`”) to conserve space on the command line.

When you descend to lower modes in the config tree, the prompt offers more information. To extend the previous example, suppose you enter the following command to configure the “`/local`” volume in the `wwmed` namespace:

```
bstnA(gbl-ns[wwmed])# volume /local
bstnA(gbl-ns-vol[wwmed~/local])#
```

The tilde character (`~`) separates a parent object from its child: “`wwmed~/local`” shows that you are in the “`/local`” volume under the “`wwmed`” namespace.

The no Convention

Most config commands have the option to use the “`no`” keyword to negate the command. For commands that create an object, the `no` form removes the object. For commands that change a default setting, the `no` form reverts back to the default. As an example,

```
bstnA(gbl-ns[wwmed])# no volume /local
```

removes the “`/local`” volume from the “`wwmed`” namespace.

The enable/no enable Convention

Many objects and configurations require you to enable them using the `enable` command before they can take effect. Likewise, many objects and configurations require you to first disable them using the `no enable` command before you can complete a related command or function. The `no`

`enable` command does not remove an object; it only disables it until you re-enable it. The `enable/no enable` commands exist in many modes and submodes in the CLI.

For example, the following command sequence enables the namespace named “`wwmed:`”

```
bstnA(gbl)# namespace wwmed
bstnA(gbl-ns[wwmed])# enable
bstnA(gbl-ns[wwmed])# ...
```

Getting Started

For the initial login, refer to the instructions for booting and configuring the switch in the appropriate *Hardware Installation Guide*.

For subsequent logins, use the following steps to log into the F5 CLI:

1. If you are on-site, you can connect a serial line to the serial console port. This port is labeled 'Console' or '10101' (depending on your ARX platform). By default, the port is set for 9600 baud, 8, N, 1.

You can also telnet to the switch's management interface. For example:

```
telnet 10.10.10.10
```

In either case, a login prompt appears:

Username:

2. Enter your username and password. For example:

```
Username: admin  
Password: acopia
```

The CLI prompt appears:

```
SWITCH>
```

The name, "SWITCH," is the default hostname. The hostname is reset as part of the initial-boot process, so it is likely that yours will differ.

Entering Cfg or Gbl Mode

The CLI uses two high-level modes for switch configuration: `cfg` mode for switch configuration and `gbl` mode for global configuration. Switch configuration applies to the local switch only; chassis, layer-2, and layer-3 commands are all under `cfg` mode. Global configuration applies to settings that can be shared by both switches in a redundant pair; for example, namespace-configuration commands all appear under `gbl` mode.

To enter `cfg` mode, use the **config** command from `priv-exec` mode:

```
SWITCH> enable  
SWITCH# config  
SWITCH(cfg)#
```

To enter `gbl` mode instead, use the **global** command:

```
SWITCH> enable  
SWITCH# global  
SWITCH(gbl)#
```

The command sequences in this manual all begin in either `cfg` or `gbl` mode.

Document Conventions

This manual uses the following conventions:

`this font` represents screen input and output;

- **bold text** represents input, and
- *italic text* appears for variable input or output.

this font is used for command-syntax definitions, which use the same rules for bold and italic.

Command-syntax definitions also use the following symbols:

- [*optional-argument*] - square brackets ([]) surround optional arguments;
- *choice1* | *choice2* - the vertical bar (|) separates argument choices;
- {*choice1* | *choice2* | *choice3*} - curly braces ({ }) surround a required choice;
- [*choice1* | *choice2*]* - an asterisk (*) means that you can choose none of them, or as many as desired (for example, “*choice1 choice2*” chooses both);
- {*choice1* | *choice2*}+ - a plus sign (+) means that you must choose one or more.

For commands nested in multiple layers of modes, the following convention illustrates the mode path to reach the command:

`mode1 -> mode2 -> mode3 -> command`

Command Definitions

Purpose	describes the reason for using the command.
Mode	is the mode in the CLI (for example, exec, priv-exec, or cfg).
Security Roles	<p>is the set of administrative <i>roles</i> that are allowed to access the command. Any number of administrative roles can be assigned to a command; and administrator who has one of these roles can access the command. The roles are</p> <ol style="list-style-type: none">1. operator,2. backup operator,3. network-technician,4. network-engineer,5. storage-engineer, and6. crypto-officer. <p>A command that is accessible to the <i>operator</i> is also accessible by an administrator with any other role.</p> <p>Each administrative group has one or more of these roles, assigned by using the role command.</p>
Syntax	describes the syntax of the command. This shows all keywords, arguments, and flags, and provides ranges.
Default(s)	lists all default states affected by the command and its arguments.
Valid Platforms	lists the platforms (ARX-VE, ARX-500, ARX-1500, ARX-2000, ARX-2500, and/or ARX-4000) where this command is supported. This row is omitted for universally-supported commands.
Guidelines	<p>provides context for the command, including references to related commands.</p> <p>For show commands, this section describes the output of the command.</p>
Samples	show sample input and output. For situations where the output is too wide for this table, it appears in a separate figure below.
Related Commands	are links to commands that you can use in conjunction with the current command.

Contacting Customer Service

You can use the following methods to contact F5 Networks Customer Service:

Command Keys and Shortcuts

Keys

The CLI supports the following key combinations:

<Arrows>	Move the cursor: <Up-Arrow> and <Down Arrow> go to next/previous line in command history.
<Tab>	Expand the command or keyword abbreviation.
\	Ignore any special meaning for the next character.
<Ctrl-a>	Move cursor to beginning of line.
<Ctrl-b>	Move cursor left one character.
<Ctrl-c>	Abort the current command, or exit cfg/gbl mode.
<Ctrl-d>	Delete character at cursor.
<Ctrl-e>	Move cursor to end of line.
<Ctrl-f>	Move cursor right one character.
<Ctrl-h>	Delete character to left of cursor.
<Ctrl-i>	Expand command or keyword abbreviation (same as <Tab>).
<Ctrl-k>	Delete from cursor to end of line.
<Ctrl-l>	Re-display the current line.
<Ctrl-m>	Same as <Enter> or <Return>.
<Ctrl-n>	Display next line in command history.
<Ctrl-p>	Display previous line in command history.
<Ctrl-r>	Re-display the current line.
<Ctrl-t>	Transpose current character with one to left.
<Ctrl-u>	Delete from cursor to beginning of line.
<Ctrl-w>	Delete word to left of cursor.
<Ctrl-x>	Delete everything on the current line without pressing <Enter>.
<Ctrl-z>	Return to priv mode from cfg or gbl mode.
<Esc-b>	Move cursor left one word.
<Esc-d>	Delete from cursor to end of word.
<Esc-f>	Move cursor right one word.

Chapter 2

Command Keys and Shortcuts

<Esc-c>	Capitalize character at cursor.
<Esc-m>	Toggle <i>more</i> support.
<Esc-l>	Change word at cursor to lower case.
<Esc-s>	Toggle line logging suppression.
<Esc-u>	Change word at cursor to upper case.
<Esc-bs>	Delete word to left of cursor.

3

Terminal Control

save profile

Purpose Use the `save profile` command to save the current terminal settings for future login sessions.

Modes exec and priv-exec

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `save profile`

Default(s) None

Guidelines This command saves your current terminal settings. The settings reside in a file in the configs directory, `admin-profile.scr`. The next time you log in to the switch, the CLI automatically starts with the same terminal settings. If you later change the profile and use this command again to save the change, the CLI prompts for confirmation before overwriting the `admin-profile.scr` file; enter **yes** to proceed.

Use the [show terminal](#) command to view the current terminal settings. To remove the profile, run `delete configs admin-profile.scr`.

Since an administrator with a [role](#) of “operator” does not have privileges to access priv-exec mode, exec mode also supports this command. The command operates identically in both modes.

Sample `bstnA# save profile`
saves your current terminal settings.

Related Commands [show terminal](#)

show history

Purpose Use the `show history` command to see the list of CLI commands from the current CLI session.

Mode (any)

Security Role(s) operator

Syntax `show history`

Default(s) None

Guidelines You can set the number of commands kept in the history with the [terminal history](#) command.

Sample `bstnA> show history`

```
Command History
-----
show terminal
no cli-more
show running-config
show namespace
```

```
bstnA>
```

Related Commands [terminal history](#)

show terminal

Purpose	Use the <code>show terminal</code> command to see the terminal settings for the current CLI session.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>show terminal</code>
Default(s)	None
Guidelines	<p>To save your current terminal settings, use the save profile command.</p> <p>If Terminal Idle Timeout is enabled, the system logs you out of the CLI after the idle time shown in the Terminal Idle Timeout Value field. Use terminal timeout to set the idle-timeout time.</p> <p>Terminal Expand Prompt shows the current object name in the CLI prompt. For example, if you are configuring a namespace volume, the volume name appears in the CLI prompt. Use <code>[no] terminal expand-prompt</code> to disable/enable the expanded prompt.</p> <p>Terminal Confirmation, if enabled, causes the CLI to prompt for confirmation at sensitive configuration commands. If disabled, the CLI performs all commands without prompting for confirmation. Use <code>[no] terminal confirmation</code> to disable/enable Terminal Confirmation.</p> <p>Expert Mode, if enabled, stops the CLI from prompting for confirmation when a user creates a new global-configuration object. If disabled, the CLI prompts for confirmation for every new policy, namespace, or global-server object. Use <code>[no] terminal expert</code> to disable/enable Expert Mode.</p> <p>Terminal Length is the number of lines for each page of the CLI's <i>more</i> output. (By default, the CLI pipes all of its output through <i>more</i>.) Use terminal length to reset the number of lines; use <code>terminal length 0</code> to disable the <i>more</i> feature.</p> <p>Terminal Width is the maximum number of characters in each line of CLI output. Use terminal width to reset this maximum.</p> <p>Logfile Directory only appears if terminal logging is enabled. This shows the directory where the current CLI-log file is being written; currently, this is always "reports."</p> <p>Terminal Logfile is enabled if the CLI is recording its output to a report file. Use terminal logging to enable CLI logging.</p> <p>Terminal History is the number of CLI commands kept in a history buffer. Use terminal history to set this number. To access the commands, use <code>show history</code> or <code><up-arrow></code>.</p> <p>Script History Logging indicates whether the CLI keeps terminal history for commands in CLI scripts, too. This is enabled or disabled with the <code>script</code> flag in the terminal history command.</p> <p>Terminal Character Set is either ISO 8859-1 or Unicode/UTF-8. If the latter, the terminal supports multi-byte characters (for Japanese, Chinese, and other languages with multi-byte characters). Use terminal character-set to change this.</p>

Guidelines (Cont.) Stop Scripts on error is disabled if CLI scripts continue on error. Use [terminal stop-on-error](#) to stop CLI scripts that encounter an error.

If [terminal beta](#) is enabled, you can preview and test the CLI beta test commands available in later versions of F5 software. Contact your F5 representative for more information on these commands. Use [no] [terminal beta](#) to disable/enable previewing the beta test commands.

Sample bstnA> show terminal
Terminal Options

Terminal Idle Timeout:	disabled
Terminal Idle Timeout value:	
Terminal Expand Prompt:	enabled
Terminal Confirmation:	enabled
Expert Mode:	disabled
Terminal Length:	24 lines, more disabled
Terminal Width:	80
Terminal Logfile:	disabled
Terminal History:	10 lines
Script History Logging:	disabled
Terminal Character Set:	ISO 8859-1
Stop Scripts on error:	disabled
Beta Commands:	disabled

Related Commands [terminal timeout](#)
[terminal expand-prompt](#)
[terminal confirmation](#)
[terminal length](#)
[terminal width](#)
[terminal logging](#)
[terminal history](#)
[show history](#)
[terminal character-set](#)
[terminal beta](#)

terminal beta

Purpose	Use the <code>terminal beta</code> command to unlock CLI beta test commands. Use the <code>no</code> form of the command to lock these commands.
Mode	priv-exec
Security Role(s)	network-technician, network-engineer, storage-engineer, or crypto-officer
Syntax	<code>terminal beta</code> <code>no terminal beta</code>
Default(s)	no terminal beta
Guidelines	<p>The <code>terminal beta</code> command provides access to the CLI beta test commands to be released in later versions of F5 software. Use <code>terminal beta</code> to unlock these commands for previewing and testing purposes only. Contact your F5 representative for more information on the availability of these commands.</p> <p>Entering <code>terminal beta</code> causes the beta test commands to appear in Help.</p> <p>Use <code>show terminal</code> to find the current setting (locked or unlocked) for the beta test commands.</p>
Samples	<pre>bstnA> terminal beta</pre> <p>This command unlocks UNSUPPORTED features. Are you sure? [yes/no] yes unlocks the beta test commands and features.</p> <pre>bstnA> no terminal beta</pre> <p>hides all beta commands and features.</p>
Related Commands	show terminal

terminal character-set

Purpose	Use this command to enable or disable CLI support for Unicode characters (such as the characters used in Chinese or Japanese languages). Match this to the character set used in the local network.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	terminal character-set {iso-8859-1 unicode-utf-8} no terminal character-set
Default(s)	iso-8859-1
Guidelines	<p>The terminal character set is the one that was used in your network before the ARX was installed. The correct character setting is required so that you can enter back-end filer names into the CLI, and so that the CLI can properly display filer names and service names in its show commands.</p> <p>The iso-8859-1 setting is for single-byte-character languages like English. The other setting, unicode-utf-8, supports all languages including those with characters larger than one byte.</p> <p>You can use Unicode characters for naming objects such as filers and back-end shares. They are not used in CLI prompts, help, or error messages.</p> <p>To view the current character set, use show terminal.</p>
Samples	<pre>bstnA> terminal character-set unicode-utf-8</pre> <p>allows multi-byte characters.</p> <pre>bstnA> no terminal character-set</pre> <p>restricts the CLI to single-byte characters only.</p>
Related Commands	show terminal

terminal clear

Purpose Use this command to clear the screen of all text entries. It is also useful in writing scripts.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `terminal clear`

Default(s) None

Guidelines Use this command when you want to clear the screen and start over. It is also useful for capturing screen output, scripting, and pausing a CLI operation.

Sample `bstnA> terminal clear`
clears the screen of all entries and returns you to the CLI prompt (in the same mode) at the top of the screen.

Related Commands [show terminal](#)
[reload](#)

terminal confirmation

Purpose Some sensitive configuration commands require user confirmation (for example, “Are you sure? [y/n]”). For non-interactive scripts, you can disable the confirmations with `no terminal confirmation`.

Use the affirmative form, `terminal confirmation`, to make the CLI start prompting for confirmations again.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `terminal confirmation`
`no terminal confirmation`

Default(s) Enabled

Guidelines Use [show terminal](#) to find the current setting for terminal confirmation.

Samples `bstnA(cfg)# no terminal confirmation`
disables terminal-confirmation prompts. For example, if you reboot the ARX the confirmation message (“Are you sure? [y/n]”) will be skipped.

`bstnA(cfg)# terminal confirmation`
reinstates terminal-confirmation.

Related Commands [show terminal](#)

terminal expand-prompt

Purpose	Use the <code>terminal expand-prompt</code> command to display the fully expanded CLI command prompt. Use the <code>no</code> version of the command to shorten the CLI command prompt (mode only).
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>terminal expand-prompt</code> <code>no terminal expand-prompt</code>
Default(s)	Enabled
Guidelines	The expand-prompt feature shows the name of the current object (such as the namespace or volume) in the prompt. The show terminal command indicates whether or not this feature is enabled.
Samples	<pre>bstnA(gbl-ns[[nfsNamespace1]])#no terminal expand-prompt disables the expanded prompt: bstnA(gbl-ns[nfsNamespace1])# terminal expand-prompt bstnA(gbl-ns[nfsNamespace1])# reinstates the expanded prompt.</pre>
Related Commands	show terminal

terminal expert

Purpose	Commands that create new configuration objects (such as namespaces and global servers) prompt for confirmation before creating the object. Use the terminal expert command to remove these confirmation prompts. Use the no version of the command to bring back the confirmation prompts.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	terminal expert no terminal expert
Default(s)	no terminal expert
Guidelines	This command only applies to confirmations for new configuration objects; use no terminal confirmation to eliminate all confirmation prompts in the CLI. The CLI prompts for all new configuration objects by default. This is a feature for safeguarding against typing mistakes.
Samples	<pre>bstnA(gbl-ns[nfsNamespace1])# terminal expert</pre> disables prompts for new objects (like namespaces). <pre>bstnA(gbl-ns[[nfsNamespace1])# no terminal expert</pre> re-enables the safe prompts.
Related Commands	terminal confirmation show terminal

terminal history

Purpose	The CLI keeps a configurable number of CLI commands in a list, so that you can display the list with the <code>show history</code> command. Use the <code>terminal history</code> command to set the number of CLI commands to keep. Use the <code>no</code> form of this command stop saving any CLI history.
Mode	(any)
Security Role(s)	operator
Syntax	<code>terminal history <i>number</i></code> <code>terminal history <i>script</i></code> <code>no terminal history [<i>script</i>]</code> <i>number</i> (0-255) is the number of CLI commands to keep in the terminal-history list. <i>script</i> (optional) enables logging for CLI scripts. If the <code>run</code> command invokes a script, the CLI keeps terminal history for the commands in the script, too.
Default(s)	10 lines script history is not kept
Guidelines	Use <code>show history</code> to view the terminal history. You can also use the up-arrow key to view the history one command at a time.
Samples	<code>bstnA(cfg)# terminal history 100</code> keeps 100 CLI commands in the terminal history. <code>bstnA(cfg)# terminal history script</code> keeps terminal history for commands in CLI scripts as well as those entered by an administrator. <code>bstnA(cfg)# no terminal history</code> disables terminal history.
Related Commands	<code>show history</code> <code>show terminal</code>

terminal length

Purpose By default, the CLI pipes all of its output through the *more* paging program. Each page of *more* output has a configurable number of lines; use the **terminal length** command to set the number of lines in each CLI page.

Use **no terminal length** to return to the default length and enable the *more* feature.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax **terminal length** *number*
no terminal length

number (0-255) is the number of lines in each page of CLI output. 0 (zero) means “infinite;” this effectively disables the CLI *more* feature.

Default(s) 24 (and see the *Guidelines* below)

Guidelines The default terminal length applies to serial connections to the Console port as well as remote connections to one of the IP-based management ports. However, if a remote connection (such as a Telnet session) has a length setting, it overrides the default. If this command sets a specific length, it overrides both.

Use **terminal length 0** to disable the *more* feature. The **no terminal length** command enables the *more* feature and returns the length to the default.

Use [terminal width](#) to determine the number of characters in each line of CLI output. Use [show terminal](#) to find the current terminal length, and to find whether or not *more* is disabled.

Samples bstnA(cfg)# **terminal length 200**
sets each page of CLI output to 200 lines.

bstnA(cfg)# **terminal length 0**
allows for unlimited output. This effectively disables the *more* paging feature.

bstnA(cfg)# **no terminal length**
reverts the page length to the default.

Related Commands [terminal width](#)
[show terminal](#)

terminal logging

Purpose Use the `terminal logging` command to capture output from CLI `show` commands to a report file. This starts a session where the output of all subsequent CLI commands is recorded in the report file.

Use the `no` form of this command to stop the current terminal-logging session.

Mode (any)

Security Role(s) operator (any, including backup-operator)

Syntax `terminal logging [report-prefix]`
`no terminal logging`

report-prefix (optional, 1-1024 characters) is the prefix for a report file. The CLI logs its output to a report file named as follows:

report-prefix_yyyyymmddHHMM.rpt, where *report-prefix* is chosen here, *yyyy* is the current year, *mm* is the current month, *dd* is the day, *HH* is the hour, and *MM* is the minute.

The default prefix is “cli_.”

Default(s) Disabled

report-prefix -”cli_.”

Guidelines The CLI displays the name of the report file when you enter the command. Use [show reports](#) type CLI to view all CLI-log reports, or [show reports report-name](#) to view a specific CLI-log file.

The [show terminal](#) command indicates whether or not terminal logging is enabled.

Samples `bstnA(cfg)# terminal logging showoutput`

Generating CLI output report: 'showoutput_200903301531.rpt'..

enables terminal logging and captures `show` command output to the named log file.

`bstnA(cfg)# no terminal logging`

disables terminal logging.

Related Commands [show reports](#)
[show terminal](#)

terminal stop-on-error

Purpose	In CLI scripts, use <code>terminal stop-on-error</code> to stop script processing if the CLI responds with an error. Use <code>no terminal stop-on-error</code> to continue processing the CLI script through all errors.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>terminal stop-on-error</code> <code>no terminal stop-on-error</code>
Default(s)	no terminal stop-on-error
Guidelines	Use <code>show terminal</code> to find the current setting (enabled or disabled) for stop-on-error. Use <code>copy ... scripts <i>script-name</i></code> to download a CLI script onto the switch.
Samples	<code>bstnA(cfg)# terminal stop-on-error</code> stops processing on a CLI error. <code>bstnA(cfg)# no terminal stop-on-error</code> allows a CLI script to continue processing through all errors.
Related Commands	<code>copy ftp</code> <code>copy scp</code> <code>copy tftp</code> <code>copy {nfs cifs}</code> <code>show terminal</code>

terminal timeout

Purpose By default, a CLI terminal logs off after 15 minutes of idle time, where idle time is time without any user input. Use `no terminal timeout` to allow infinite idle time. Use the affirmative form, `terminal timeout`, to re-instate time-outs.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `no terminal timeout`
`terminal timeout`
`terminal timeout seconds`

seconds (0-2048) is the number of idle seconds before timing out the current CLI session. If you omit this value with the `terminal timeout` command, you set the default timeout of 900 (seconds, or 15 minutes).

Default(s) 900 (seconds, or 15 minutes) of idle time

Guidelines Use [show terminal](#) to find the current setting (enabled or disabled) for terminal time-out.

Samples `bstnA(cfg)# no terminal timeout`
allows the terminal to be idle for infinite time without logging off.

`bstnA(cfg)# terminal timeout`
reinstates terminal-timeout at its default, 900 seconds.

`bstnA(cfg)# terminal timeout 1800`
sets the terminal-timeout 1800 seconds, or 30 minutes.

Related Commands [show terminal](#)

terminal width

Purpose	Use the <code>terminal width</code> command to set the maximum number of characters in each line of CLI output. Use <code>no terminal width</code> to return to the default width.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>terminal width <i>number</i></code> <code>no terminal width</code> <i>number</i> (0-255) is the maximum number of characters in each line of CLI output.
Default(s)	80 (and see the <i>Guidelines</i> , below)
Guidelines	The default terminal width applies to serial connections to the Console port as well as remote connections to one of the IP-based management ports. However, if a remote connection (such as a Telnet session) has a width setting, it overrides the default. If this command sets a specific width, it overrides both. Use terminal length to determine the number of lines in each page of CLI output. Use show terminal to find the current terminal width.
Samples	<code>bstnA(cfg)# terminal width 120</code> sets each line of CLI output to 120 characters. <code>bstnA(cfg)# no terminal width</code> returns to the default line width.
Related Commands	terminal length show terminal

4

Administrative Users

group

Purpose An administrative *group* defines the access privileges for a list of administrative users. Use the **group** command to add a new group to the ARX, or to edit an existing group. You can also use this command to re-create or edit a Windows group, so that you can assign administrative privileges to the group's Windows users.

Use the **no** form of this command to remove a group.

Mode gbl

Security Role(s) crypto-officer

Syntax **group** *name*
no group *name*

name (1-64 characters) is a name that you choose for the group. Surround this with quotation marks (""") if it contains any spaces.

Default(s) Several default groups are defined, each with different access privileges: crypto-officer, storage-engineer, network-engineer, network-technician, backup-operator, and operator.

Guidelines This command puts you into gbl-group mode. From gbl-group mode, you can use the **role** command to select a *role* for all the group's users. Each role is associated with a set of CLI commands; you can use the **role** command multiple times to assign multiple roles to a group. You must set at least one role for the group to function. Default groups (such as network-engineer) already have their roles configured.

For a group of Windows administrators, defined externally in your Active Directory, you can choose a group *name* that is the same as an existing Windows group. For example, you could create a group named "Domain Admins." Then use the **windows-domain (gbl-group)** command to specify one or more domains where the group is allowed access; Domain Admins in "medarch.org" may be allowed to access the CLI, but Domain Admins in "competitor.com" may not. Finally, use the **authentication** command to allow Active-Directory authentications at the CLI and/or GUI. Windows users in the group/domain can then log into the CLI or GUI with their Windows username and password, and they get the access privileges assigned by the **role** command. This type of group does not require any users; all users are established externally, on your Windows Domain Controllers.

For a locally-defined group of administrators, use the **user (gbl-group)** command to add each administrator to the group.

Use the **show group all** command for a list of existing groups.

Samples bstnA(gbl)# **group superusers**
bstnA(gbl-group[superusers])#
creates the group, "superusers."

bstnA(gbl)# **group "Domain Users"**
creates another group, "Domain Users."

Related Commands [role](#)
[windows-domain \(gbl-group\)](#)
[authentication](#)
[user \(gbl-group\)](#)
[show group all](#)

group (gbl-user)

Purpose Use the `group` command to add the current user to an additional group. Use `no group` to remove the current user from a group.

Mode gbl-user

Security Role(s) crypto-officer

Syntax `group name`
`no group name`

name (1-64 characters) is a name of an existing group.

Default(s) None

Guidelines A user can belong to multiple groups, where each group is associated with a [role](#). The group's role determines the access privileges for its users. Every command in this manual is labeled with the role or roles that are permitted to use the command. See *Security Role(s)*, above, as an example: this command can only be used by users who belong to groups with the "crypto-officer" role.

The ARX is shipped with several pre-defined groups. Use the [show group all](#) command to show all groups, and use [show group roles](#) to show the role associated with each group. You can add new groups with the [group](#) command.

Samples `bstnA(gbl-user[newuser])# group storage-engineer`
adds the "newuser" account to a group, "storage-engineer."

`bstnA(gbl-user[newuser])# no group testgroup2`
removes the "newuser" account from the "testgroup2" group.

Related Commands [group](#)
[show group all](#)
[show group roles](#)

password

Purpose Use this command to change the password for your administrative-user account, the one used for your current login session.

Mode priv-exec

Security Role(s) crypto-officer, storage-engineer, network-engineer, or network-technician

Syntax password

Default(s) None

Guidelines The CLI first authenticates you by prompting for the old password. Then it prompts for the new password that you want, followed by a prompt to re-enter the new password. The maximum number of characters is 28. For maximum security, choose a password with at least one of each of the following:

- lower-case letter (a-z),
- upper-case letter (A-Z),
- number (0-9), and
- non alpha-numeric symbol (\$, #, *, @, and so forth). You cannot use any of the following characters: | & ; () < > ` -.

An administrator with the crypto-officer role can use the [password \(gbl-user\)](#) command to change the password for any user account.

Sample bstnA# password
Old Password: **acopia**
New Password: **myNewPa\$\$wd**
Validate Password: **myNewPa\$\$wd**
bstnA#

changes the password for the current account.

Related Commands [password \(gbl-user\)](#)

password (gbl-user)

Purpose	Use the <code>password</code> command to change the password for an administrative-user account.
Mode	<code>gbl-user</code>
Security Role(s)	<code>crypto-officer</code>
Syntax	<code>password</code>
Default(s)	None
Guidelines	<p>This command changes the password for an administrative-user account that is not necessarily your own. A crypto officer can use this command to manage administrative accounts on the ARX. To change the password on the current account, any administrator can use the <code>password</code> command from <code>priv-exec</code> mode.</p> <p>This only applies to locally-defined accounts. It has no effect on user accounts defined externally in the Windows Active Directory. (See windows-domain (gbl-group) for information about allowing externally-defined users to access the ARX as administrators.)</p> <p>The CLI prompts for a new password for the account, then prompts you to re-enter the same password. The maximum number of characters is 28. For maximum security, choose a password with at least one of each of the following:</p> <ul style="list-style-type: none">• lower-case letter (a-z),• upper-case letter (A-Z),• number (0-9), and• non alpha-numeric symbol (\$, #, *, @, and so forth). You cannot use any of the following characters: & ; () < > ` -. <p>Use the <code>show users</code> command to show all administrative users.</p>
Sample	<pre>bstnA(gbl-user[newuser])# password Password: n3wcrypt1cPa\$\$wd Validate Password: n3wcrypt1cPa\$\$wd bstnA(gbl-user[newuser])#</pre> <p>changes the password for the “newuser” account.</p>
Related Commands	user show users

role

Purpose A group's *role* determines the accessible CLI commands for its administrative users. Each group can have multiple roles. Use the `role` command to set a role for the current group.

Use the `no role` command to remove a role from the group.

Mode gbl-group

Security Role(s) crypto-officer

Syntax `role {operator | backup-operator | network-technician | network-engineer | storage-engineer | crypto-officer}`
`no role {operator | backup-operator | network-technician | network-engineer | storage-engineer | crypto-officer}`

Select one of the following roles:

operator is a clerical administrator,

backup-operator runs backup and restore operations on volumes (see [restore data](#)),

network-technician configures layer-2 and IP networks under the guidance of a network-engineer,

network-engineer designs network topologies,

storage-engineer designs and configures network storage, and

crypto-officer keeps passwords and manages network security.

Default(s) None

Guidelines Each role is associated with a set of CLI commands. Administrators with the storage-engineer role, for example, have access to commands that are associated with storage management. Use [show group roles](#) to show all configured groups and roles.

Each CLI command has one or more *Security Roles* that are listed in this manual. If an administrator's group has one of the roles that can access a command, the administrator can use the command. For example, an administrator with the **network-technician** role can see a command that is assigned to **network-engineer** and **network-technician**, but cannot see a command that allows only **storage-engineers**.

Administrators with the crypto-officer role can log into a booting ARX sooner than administrators with other roles. Other roles wait until gbl mode is accessible before allowing a login, whereas a crypto officer can log in as soon as cfg mode is available.

Samples `bstnA(gbl-group[Domain Admins])# role crypto-officer`
adds the "crypto-officer" role to the "Domain Admins" group.

`bstnA(gbl-group[superusers])# no role network-technician`
removes the "network-technician" role from the "superusers" group.

Related Commands [group](#)
[show group roles](#)

ssh-key

Purpose	Use the <code>ssh-key</code> command to paste a public SSH key into the current administrative account. Use the <code>no ssh-key</code> command to remove one or more SSH keys from the current account.
Mode	gbl-user
Security Role(s)	crypto-officer
Syntax	<p><code>ssh-key {dsa rsa rsa1} [<i>public-key</i>]</code></p> <p><code>dsa rsa rsa1</code> is a required choice, which selects the encryption type and SSH version for the key:</p> <ul style="list-style-type: none"> <code>dsa</code> is DSA over SSHv2, <code>rsa</code> is RSA over SSHv2, and <code>rsa1</code> is RSA over SSHv1. By default, SSHv1 is not supported, use ssh-v1 enable to enable SSHv1 support. <p><i>public-key</i> (optional, 1-2500 characters) is a public SSH key, pasted from the client. Use quotation marks around this string, as it invariably contains spaces. Take care that the copy/paste operation does not add any <Return> or <Line-Feed> characters to break up the string. If you omit the <i>public-key</i>, the CLI prompts for it on the next line.</p>
Syntax: No Form	<p><code>no ssh-key id <i>key-id</i></code></p> <p><code>no ssh-key fingerprint <i>fingerprint</i></code></p> <p><code>no ssh-key {dsa rsa rsa1}</code></p> <p><code>no ssh-key all</code></p> <p><i>key-id</i> (1-2,147,483,647) identifies the SSH key by an ID number assigned at the switch. Use show ssh-user to see all key IDs for all SSH keys.</p> <p><i>fingerprint</i> (1-50) identifies the SSH key by its fingerprint. Use show ssh-user to see all fingerprints.</p> <p><code>dsa rsa rsa1</code> identifies the type of key to remove. This removes all SSH keys of the given type from the current administrative account.</p> <p><code>all</code> removes all SSH keys from the current administrative account.</p>
Default(s)	None
Guidelines	<p>When administrators access the CLI through SSH, they are typically challenged for the account password. The SSH protocol supports <i>public-key authentication</i>, which skips this challenge. When an administrator accesses SSH on the switch, the switch's SSH server attempts to use the administrator's public-key first. If the public key is configured properly for this administrator, he or she never sees a password challenge.</p> <p>An administrator's SSH keys are unique to every client machine that they use. You can therefore configure multiple SSH keys for each administrative user account.</p> <p>The show ssh-user command shows all administrative accounts with SSH public keys.</p>

Samples `bstnA(gbl-user[su])# ssh-key dsa "ssh-dss

```

adds the same SSH key by responding to a CLI prompt.

```
bstnA(gbl-user[su])# no ssh-key rsa
```

removes all RSA/SSHv2 keys from the "su" user account.

```
bstnA(gbl-user[admin])# no ssh-key id 7
```

removes SSH-key 7 from the "admin" user account.

show group roles

Purpose Each group has a *role* which defines CLI-access privileges for the group's users. Use the `show group roles` command to show all administrative groups and their roles.

Mode (any)

Security Role(s) crypto-officer

Syntax `show group roles`

Guidelines This shows a table with two columns: administrative groups in the left column and their roles in the right column.

Use the `group` command to configure a new group.

Use the `role` command to set a group's role.

Use the `show group users` command to find the administrative users in each locally-defined group.

Sample `bstnA(gbl-group[admins])# show group roles`

Group Roles

Group	Roles
-----	-----
Administrators	backup-operator
Administrators	operator
Administrators	network-engineer

operator             admin
```

show ssh-user

Purpose Use the `show ssh-user` command to show the SSH public keys entered for administrative users, if any.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, and operator

Syntax `show ssh-user [account-name]`

account-name (optional, 1-32 characters) identifies a particular administrative account to show. If you omit this, the SSH keys are shown for all administrative accounts.

Guidelines Each administrative account can store multiple SSH public keys. Each public key corresponds to one administrator on one SSH-client machine; if the administrator's public key is copied from the client machine to the administrative account, the administrator can access the account through SSH without providing a password.

This shows a table with one row per SSH public key. Each row has the following information:

User is the name of the administrative-user account, set with the `user` command.

KeyId is an internally-assigned ID for this public key. You can use this with `no ssh-key id` to remove the SSH key from the account.

Type is "dsa" (DSA encryption over SSHv2), "rsa" (RSA encryption over SSHv2), or "rsa1" (RSA encryption over SSHv1).

Fingerprint is used by SSH as a shorter equivalent to the public key. This is a unique identifier for a particular user at a particular host. You can use this with `no ssh-key fingerprint` to remove the SSH key from the account.

Samples `bstnA# show ssh-user`
lists the SSH public keys configured for all administrative accounts. See [Figure 4.3](#) for sample output.

`bstnA# show ssh-user admin`
lists the SSH public keys for one account only, "admin." See [Figure 4.4](#).

Related Commands [user](#)

```
bstnA#
```

show users

Purpose Use the `show users` command to display all administrative users that have been locally configured for the ARX.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show users`

Guidelines The output contains two tables.

Configured Users is a list of all local administrative users. Use the `user` command to configure a new local user. This does not show any users defined externally in the Windows Active Directory.

Current User shows login name used for the current administrative session. The first set of rows under the user name is the `group(s)` to which the current user belongs. Each of these rows is labeled “group.” If you logged in through Active Directory, using your Windows credentials, there is another set of rows labeled “role:” these are the administrative `roles`, or privileges, assigned to you.

Use the `show group all` command to show all administrative groups.

Sample `bstnA(gbl)# show users`

```
Users
  Configured Users
  -----
  adm1
  adm12
  admin
  newadmin

  Current User
  -----
  medarch\administrator
    group  Domain Admins
    group  Enterprise Admins
    group  Domain Users
    role   operator
    role   network-engineer
    role   storage-engineer
    role   crypto-officer
    role   backup-operator
```

Related Commands `user`
`show group all`

user

Purpose Use the `user` command to add a new, local administrative user to the ARX.
Use the `no` form of this command to remove a user account.

Mode gbl

Security Role(s) crypto-officer

Syntax `user username`
`no user username`

username (1-32 characters) is a username that you choose.

Default(s) operator is the default group for a new user

Guidelines If the user account is new, the CLI prompts for a password. The maximum number of characters is 28. For maximum security, choose a password with at least one of each of the following:

- lower-case letter (a-z),
- upper-case letter (A-Z),
- number (0-9), and
- non alpha-numeric symbol (\$, #, *, @, and so forth). Avoid the characters listed above for *username*.

If you use this command to edit an existing account, there is no password prompt.

This puts you into `gbl-user` mode, which has commands for editing the user account. Use the [password](#) command to change the password for the account. For administrators that use SSH to access this account, you can use the [ssh-key](#) command to add their public key to the account; if they log in from a management station with the same public key, they do not have to enter the account password.

A user's *group* determines its CLI-access privileges. A new user's default group, operator, has minimal access privileges. Each user can belong to multiple groups, thereby expanding his access privileges. After you create the user account with this command, you can use the [group \(gbl-user\)](#) command to add this user to another group.

Use the [show users](#) command to show all administrative users.

Samples

```
bstnA(gbl)# user newuser
Password: crypt1cPa$$wd
Validate Password: crypt1cPa$$wd
bstnA(gbl-user[newuser])#
    creates the user, "newuser," with the password, "crypt1cPa$$wd."
```

Related Commands [password](#)
[ssh-key](#)
[group \(gbl-user\)](#)
[show users](#)

user (gbl-group)

Purpose Use the gbl-group `user` command to add a local administrative user to the current group.

Use `no user` to remove a local user from the current group.

Mode gbl-group

Security Role(s) crypto-officer

Syntax `user username`
`no user username`

username (1-64 characters) identifies an administrative user account on this ARX. Use [show group users](#) for a list of all available user accounts.

Default(s) None

Guidelines This command adds a user to the current group. The `no` form of the command removes a user, thus revoking the group privileges for that user. These administrative users are locally defined on the ARX.

This command is unnecessary for a Windows group that is defined in your Active Directory (AD). For a group defined in the AD, you can use the [windows-domain \(gbl-group\)](#) command to specify the domain(s) where the group's users can gain access to the ARX. Any valid Windows user in the group and domain can use their Windows username and password to gain access. The users are defined externally, on your Windows Domain Controllers.

Sample `bstnA(gbl-group[superusers])# user newuser`
adds "newuser" to the current group.

Related Commands [group](#)
[show group users](#)

windows-domain (gbl-group)

Purpose An administrative group can be equivalent to one or more Windows groups in your Active Directory. If the group name is the same as a valid Windows-group name, you can allow the group's Windows users to log into the CLI and/or GUI with their Windows credentials. This command declares a valid Windows domain for the current Windows group. You can re-issue the command multiple times to allow access to this group in multiple trusted domains.

Use the **no** form of the command to remove a Windows domain from the group configuration. This prevents the Windows users from the given domain/group from logging in with their Windows credentials.

Mode gbl-group

Security Role(s) crypto-officer

Syntax **windows-domain** *domain-name*
no windows-domain *domain-name*
no windows-domain **all**

domain-name (1-256 characters) is the name of the Windows domain for this Windows group. This must be a Fully-Qualified-Domain Name (FQDN) so Windows users can log in with it. This makes it possible for Windows users to authenticate with Kerberos.

all (optional with the **no** form) removes all of the Windows domains that have been associated with this group.

Default(s) None

Guidelines This command establishes a Windows domain where the group has administrative privileges. This implies that the group name exists in the Active-Directory configuration (outside the ARX), that the group is valid in this Windows domain, and that one or more of the group's users should have administrative access to the ARX.

The [role](#) command establishes the administrative permissions for members of this group. To see the current roles for the group, use [show group roles](#).

You must also configure the GUI and/or the CLI to allow Active-Directory (AD) authentication. To open a given access point (such as HTTP or HTTPS for the GUI) for AD authentication, use the [authentication](#) command.

Sample

```
bstnA(gbl-group[Domain Users])# windows-domain medarch.org
```

 declares that Windows clients from the "Domain Users" group in "medarch.org" can gain administrative access to the ARX.

Related Commands [group](#)

5

Chassis Management

This chapter contains an alphabetical list of commands for managing the chassis of the ARX.

Slot Locations

Some of these commands require module identification by slot ID.

The ARX-4000 has two “slots,” 1 and 2. The smaller ARX-500, and ARX-2000 platforms have a single “slot,” slot 1. The virtual ARX-VE is said to also have a single, virtual slot: also slot 1.

clear metalog usage

- Purpose** Namespace software and networking software record important log information, called *metalog* data, to be used by a redundant peer in the event of a failover. The ARX-1500 and ARX-2500 store their metalog data on internal disk partitions. You can use the [show metalog usage](#) command to view the usage of these metalog partitions over time. Use this command to clear the metalog-usage statistics for the current ARX.
- Mode** priv-exec
- Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer
- Syntax** `clear metalog usage`
- Default(s)** None
- Valid Platforms** ARX-1500 and ARX-2500
- Guidelines** The [show metalog usage](#) command shows up-to-date usage statistics for all metalog partitions in the ARX. Use this command to clear those usage statistics for the entire system.
- The CLI prompts for confirmation before clearing any statistics; enter **yes** to continue.
- The [show metalog usage](#) command is unavailable for a minute after you issue this command.
- Sample**
- ```
stoweA# clear metalog usage
Clear metalog statistics? [yes/no] yes
Metalog driver usage statistics will not be available for a minute.
clears the metalog-usage statistics for the ARX named "stoweA."
```
- Related Commands** [show metalog usage](#)

---

## clear nvr

|                         |                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The Non-Volatile RAM (NVRAM) is battery-backed memory on the ACM. The NVRAM stores all database transactions for the namespace processes; if the processes fail, they can recover by replaying these transactions. These transactions are called <i>metalog</i> data. If the NVRAM gets corrupted somehow, use the <code>clear nvr</code> command to erase it and reboot the chassis. |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Security Role(s)</b> | network-technician, network-engineer, storage-engineer, or crypto-officer                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>           | <code>clear nvr [reload]</code><br><br><b>reload</b> (optional) causes the switch to come back online after halting. If you omit this option, the switch halts until you manually restore power.                                                                                                                                                                                      |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Valid Platforms</b>  | ARX-500, ARX-2000, or ARX-4000                                                                                                                                                                                                                                                                                                                                                        |
| <b>Guidelines</b>       | The CLI prompts you with a warning before it clears the NVRAM. Enter <b>yes</b> to continue, then enter your username at the next prompt. The switch then halts. If you omitted the <b>reload</b> option, you must turn the power back on to restore the ARX to service.                                                                                                              |

### Important

---

*This causes namespace corruption in a running switch, in addition to a service interruption. Only use this command on the advice of F5 personnel.*

The following events are appropriate for clearing the NVRAM:

- When the system is first booted. This brings the NVRAM battery online for the first time, so there may be some garbled data and pre-startup ECC errors.
- After a hardware failure where the NVRAM got corrupted with ECC errors. Use the `show chassis [nvr]` command to check for non-recoverable ECC errors.
- (Optional) After clearing all namespaces with `delete startup-config` and rebooting. This eliminates stale namespace data in the NVRAM.

**Sample** `bstnA# clear nvr reload`

```
WARNING WARNING WARNING WARNING WARNING WARNING WARNING WARNING
```

This will erase the non-volatile RAM (NVRAM).

The effects are:

- All pending namespace transactions will be lost.

- Any data that is in transition may become corrupted.

- The chassis will reload immediately after clearing the NVRAM.

This should only be done on a switch that has been completely unconfigured and removed from the network, or on the advice of technical support.

Are you sure you want to clear non-volatile RAM and reload the system?

[yes/no] **yes**

Please enter your userid to confirm clearing the non-volatile RAM:

**admin**

```
% INFO: Success clearing non-volatile RAM. Rebooting system....
```

```
System is resetting.
```

```
...
```

**Related Commands** [delete startup-config](#)

---

# clock set

**Purpose** Use the `clock set` command to set the time and/or date at the ARX.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `clock set HH:MM:SS`  
`clock set HH:MM:SS mm/dd/yyyy`

*HH:MM:SS* is the time (for example, 06:00:00). Enter the local time, not the UTC time.

*mm/dd/yyyy* (optional) sets the date (for example, **12/31/2003** for the 31st of December, 2003).

**Default(s)** If you omit the date specification, the date is unchanged.

**Guidelines** Several processes, including those for RON, redundancy, and policy, have clock-dependant algorithms that can be confused by a major change in time. In general, you should avoid this command and use an NTP server instead (see below). For this reason, the CLI prompts for confirmation before changing the time; enter **yes** to proceed.

This command is unnecessary if you use the `ntp server` command to synchronize the time to an accurate time source. An NTP server overrides the time you set with this command. For the reason stated above, NTP is strongly recommended.

Use the `show clock` command to view the current time and date setting.

**Samples** `bstnA# clock set 11:00:00`  
Changing the time may have an adverse impact on the switch.

Are you sure? [yes/no] **yes**  
sets the clock to 11 AM, local time.

`bstnA# clock set 23:30:00`  
Changing the time may have an adverse impact on the switch.

Are you sure? [yes/no] **yes**  
sets the clock to 11:30 PM.

`bstnA# clock set 23:30:00 10/24/2004`  
Changing the time may have an adverse impact on the switch.

Are you sure? [yes/no] **yes**  
sets the clock to 11:30 PM on October 24, 2004.

**Related Commands** `ntp server`  
`show clock`

## clock timezone

**Purpose** Use the `clock timezone` command to set the time zone at the ARX.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `clock timezone region city`  
`clock timezone time-zone-name`  
`clock timezone offset`

*region* (1-64 characters) is the continent or ocean of the closest major city. Use **<Tab>** to see a list of possible options.

*city* (1-64 characters) is the closest major city. As above, use **<Tab>** to see a list of possible options.

*time-zone-name* (1-64 characters) is the name of the local time zone, if known (for example, EDT, EST, or CDT). The CLI uses this to look up the region and city. Many time-zone names are ambiguous; for example, CST maps to Central Standard Time, China Standard Time, and Australian Central Standard Time. The CLI chooses a region and city based on the current customer base. You can use [show clock](#) to see the chosen region and city.

*offset* (optional; -1400 to 1200) is the offset from Coordinated Universal Time (UTC), in hours and minutes (for example, five hours back is -0500 and 7.5 hours forward is 0730). As with the time-zone-name, the CLI uses this to look up the region and city. Many offsets are ambiguous, too; they essentially choose a longitude, and many longitudes cross through multiple cities with different time-keeping rules. The CLI chooses a region and city based on the current customer base. After you set this number, you can use [show clock](#) to see the time zone that corresponds to the offset.

**Default(s)** None

**Guidelines** A drastic clock change may have an adverse effect on policy or a number of other time-dependent applications. The CLI issues a warning before changing the time; enter **yes** to continue.

Use the [show clock](#) command to view the current time, date, and time zone settings.

**Samples** `bstnA# clock timezone America New_York`  
Changing the time may have an adverse impact on the switch.

```
Are you sure? [yes/no] yes
sets the time zone to that of New York City in the U.S.
```

```
bstnA# clock timezone EDT
...
sets the time zone to Eastern Daylight Time.
```

```
bstnA# clock timezone +0900
...
sets the time zone to 9 hours East of the Prime Meridian.
```

**Related Commands** [show clock](#)

## dual-reboot

**Purpose** Use the `dual-reboot` command to simultaneously reboot both peers in a redundant pair. Use this command only on the advice of F5 Support.

**Mode** `priv-exec`

**Security Role(s)** `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `dual-reboot`

**Default(s)** `None`

### Guidelines

#### Important

---

*This causes a service outage.*

The CLI prompts for confirmation before rebooting both peers. Enter **yes** to proceed.

This command does not work on a standalone switch, where you can use [reload](#) to reboot.

**Sample** `prtlndB# dual-reboot`

This command initiates a simultaneous reboot of both chassis in the redundant pair.

```
Do you wish to proceed? [yes/no] yes
```

```
06-16 16:02:36 Rebooting: Dual reboot request was issued
...
```

**Related Commands** [reload](#)

# hostname

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | A hostname is set for the ARX as part of the initial boot process. Use the <code>hostname</code> command to rename the ARX.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Syntax</b>           | <code>hostname <i>name</i></code><br><br><i>name</i> (up to 32 characters) is the hostname that you choose for the ARX. Use only alpha-numeric characters (0-9, a-z, A-Z), hyphens (-), and/or periods (.), as specified in RFC 1035.                                                                                                                                                                                                                                                                      |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Guidelines</b>       | <p>The hostname appears in the CLI prompt; consequently, this command changes the prompt. All ARXes in your RON should have unique hostnames. The hostname is case-sensitive: “BSTNA” is a different hostname than “bstnA.”</p> <p>This is <i>not</i> the fully-qualified domain name (FQDN) for the ARX; use the <a href="#">ip domain-list</a> command to set one or more domains for the switch.</p> <p>To create a login message for administrators, use the <a href="#">login-banner</a> command.</p> |
| <b>Sample</b>           | <pre>bstnA(cfg)# hostname usaax11 usaax11(cfg)#</pre> <p>changes the name of the current switch to “usaax11.”</p>                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Related Commands</b> | <a href="#">show hostname</a><br><a href="#">ip domain-list</a><br><a href="#">login-banner</a>                                                                                                                                                                                                                                                                                                                                                                                                            |

## login-banner

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | After an administrator accesses the CLI or the GUI, a configurable text string appears. You can use the <code>login-banner</code> command to create or edit this text string. The <code>no login-banner</code> command removes the text string.                                                                                                                                                                                                                                                                                                                                          |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Syntax</b>           | <code>login-banner post-auth {message   configs msg-file}</code><br><code>no login-banner</code><br><br><i>message</i> (1-2000 characters) is the string to show after a successful authentication. Quote this string if it contains any spaces.<br><i>configs msg-file</i> (1-1024 characters) selects a file in the configs directory and uses its text. Use the <a href="#">show configs</a> command for a list of files in the configs directory, and you can use the <a href="#">copy</a> command to download a file to that directory. This file should be no more than 768 bytes. |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>       | The login banner can contain access rules and/or a broadcast message to all ARX administrators.<br><br>In a redundant pair of ARX peers, the login banner is unique for each chassis; use this command on both peers if you want a login banner in each.                                                                                                                                                                                                                                                                                                                                 |

# probe metalog latency

**Purpose** The ARX-VE installation requires a “datastore” where the ARX stores important files, including its metalog data. Namespace software records important information in the metalog, possibly to be used later for a failure recovery. Namespace performance may suffer unless the latency to this metalog datastore is 400 micro-seconds or less. Use the `probe metalog latency` command to measure the latency between the ARX-VE and its datastore.

**Mode** `priv-exec`

**Security Role(s)** `crypto-officer` or `storage-engineer`

**Syntax** `probe metalog latency`

**Default(s)** `None`

**Valid Platforms** `ARX-VE` only

**Guidelines** Use this command after installing the ARX-VE, to confirm that the latency between the ARX-VE is sufficiently small to ensure good performance. This runs a series of I/O operations and measures the latency from each, then it shows the following values:

I/O Count is the number of I/O operations that the CLI ran.

Latency (usecs) is the average latency for all of those I/O operations, in micro-seconds.

If the latency is consistently greater than 400 micro-seconds, we recommend re-installing the ARX-VE and choosing another datastore. 250 micro-seconds or less is recommended for best performance, if that latency is feasible. The [ARX-VE Installation Guide](#) contains instructions for installing the ARX-VE.

The `show redundancy metalog` command shows similar statistics, but it applies to all platforms except the ARX-VE. The ARX-1500 and ARX-2500 store their metalog data on their internal disks. On those platforms, you can use the `show metalog usage` command to see the usage statistics for the internal metalog driver.

On all platforms, the namespace software keeps metalog read/write statistics. You can use the `show statistics metalog` command to see these metalog-usage statistics from a namespace-software perspective.

**Sample** `stkbrgA# probe metalog latency`

Statistics:

| I/O Count | Latency (usecs) |
|-----------|-----------------|
| -----     | -----           |
| 1000      | 340             |

measures and displays the latency between the current ARX-VE and its metalog datastore. This latency is acceptable.

## reload

- Purpose** Use the `reload` command to reboot the ARX. The ARX then comes up with the current “armed” software release. (By default, the “armed” release is the currently-running release; you can change it to a new release with the `boot system` command.)
- Mode** `priv-exec`
- Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`
- Syntax** `reload [collect-diags] [reason]`
- collect-diags** (optional) causes a diagnostic-collection process before the reload. This is useful for capturing the state of the ARX in case of a failure that requires further diagnosis.
- reason** (optional, 1-255 characters) is a comment you can enter to appear in syslog. This is useful when reviewing the logs during testing and diagnostics.
- Default(s)** `None`
- Guidelines** The following prompt appears for confirmation:  
`Reload the entire chassis? [yes/no/diags]`  
Enter **yes** to reboot.  
Enter **diags** if you want to collect diagnostic information and then reboot. This is equivalent to using the **collect-diags** option in the command. The collected information is a subset of the information captured by the standard `collect state` command. After the ARX reloads, use `collect diags` to gather other relevant information (along with the data collected before reboot) and upload the full diagnostic package to F5 Support.  
To power off the system and prepare it for a planned power outage, you can use the `shutdown` command.
- Guidelines: Other Applications** This command can be the final step for upgrading software on the switch. Use `reload` to restart all modules after you use `boot system` to arm the switch with a new release file. You can use `show boot` or `show version` to verify that the switch is armed with the desired release file.  
If someone deleted the full configuration (with `delete startup-config`) before running this command, all configuration changes are lost after the ARX reloads. The CLI warns you of this and prompts for confirmation; you can enter **no** and run `restore startup-config` to preserve your configuration. To remove all configuration parameters, enter **yes**.

---

**Samples** bstnA# reload

Reload the entire chassis? [yes/no/diags] **yes**

...

reloads the ARX, perhaps to complete a software upgrade.

**bstnA# reload collect-diags**

Reload the entire chassis? [yes/no] **yes**

...

collects diagnostic-state information and then reloads the ARX. After the reboot, this next command uploads that state information along with additional diagnostics:

**bstnA# collect diag-info ftp://jpublic:jpwd@ftp.wmed.com/diags**

Collect diagnostic information? [yes/no] **yes**

...

|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | <p>The <i>resource profile</i> of an ARX is the allocation of its processes amongst its CPU cores, where each CPU core is dedicated to one process type: system processes, fastpath processes, or volume-group processes. Software Release 6.2.0 introduced an optimized resource profile for the ARX-2500. An ARX-2500 with an earlier software release retains the legacy profile. The new, optimized profile is recommended. Use the <code>no resource-profile legacy</code> command to upgrade the resource profile on the current chassis.</p> <p>On the advice of F5 personnel only, you can use <code>resource-profile legacy</code> to return to the legacy profile.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Security Role(s)</b> | crypto-officer or network-engineer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Guidelines</b>       | <p>After you use this command, you must <a href="#">reload</a> the ARX-2500 for the change to take effect. If you have a redundant pair of ARX-2500 devices (see <a href="#">redundancy</a>), run this command on both peers and then use the <a href="#">dual-reboot</a> command to reboot both of them at once.</p> <p>The above is also true if you replay a running-config script with the <code>resource-profile legacy</code> setting. (One method of replaying a running-config is to save the file on the ARX-2500 and use the <code>run</code> command.) After replaying the config script, you must <a href="#">reload</a> the ARX-2500 for <code>resource-profile legacy</code> to take effect.</p> <p>The optimized resource profile assigns 3 cores, each running on separate hardware, to fastpath processes. It assigns 3 more to volume-group processing, and the remaining 2 cores to system processes.</p> <p>The legacy resource profile assigns 4 cores to fastpath processes, 2 on one hardware module and 2 on another. The cores share their hardware resources in this configuration. The legacy profile also assigns 2 more to volume-group processes and the final 2 cores to system processes.</p> <p>You can use the <a href="#">show processors</a> command to see the current resource profile on your chassis.</p> |

---

**Sample** stoweA(cfg)# no resource-profile legacy  
stoweA(cfg)# end  
stoweA# reload

Reload the entire chassis? [yes/no/diags] yes  
...

upgrades the current ARX-2500, "stoweA," to an optimized resource profile. This resource profile is generally recommended.

## show baudrate

**Purpose** Use the `show baudrate` command to show the baud rate for the Console (serial) interface.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show baudrate`

**Guidelines** The serial interface is the port labeled “Console” on the front panel.

**Sample**  
`bstnA# show baudrate`  
The serial port baud rate is 9600.

| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                              |
| <b>Syntax</b>           | <code>show chassis [chassinfo   private-subnet   diskuse   slotinfo   moduleinfo   temperature   metalog   nvr   summary]</code> |

**chassinfo** | ... | **nvr** is an optional choice to focus on one group of chassis tables. If you omit this, the command shows all groups.

**chassinfo** - specifies chassis-related tables (as opposed to slot- or module-related) with high-level environment, disk, and power supply information.

**private-subnet** - displays the private subnet that the switch uses for inter-process communication in the chassis. Every chassis in the RON (see [ron tunnel](#)) must have a unique private subnet.

**diskuse** - displays disk usage and directories on the system drive.

**slotinfo** - focuses on the slots.

**moduleinfo** - shows model information and firmware versions for each module.

**temperature** - specifies a table of sensor temperatures.

**metalog** - is only available on the ARX-1500 and ARX-2500. This option shows the statistics for metalog-driver software on this chassis. The metalog driver records important recovery data for namespace software, and (in a redundant pair) copies the data to the peer ARX.

**nvr** - is only available on the ARX-500, ARX-2000, and ARX-4000. This option shows the NVRAM-battery state and whether or not there are any ECC errors. The ARX-1500 and ARX-2500 store their metalog data on the RAID instead of the NVRAM; use the **metalog** option (above) to monitor the metalog-protection mechanism for those device types.

**summary** - shows a summary of the chassis state.

**Guidelines** The `show chassis` command displays several tables. You can focus on a smaller group of tables by using one of the optional keywords. Each group of tables is described in its own section, below.

These tables only appear if they are relevant to the current chassis type.

**Guidelines: chassinfo** The `chassinfo` section contains the following tables:

**Identification** — the hostname and the Universally-Unique ID (UUID) for the chassis. Use `hostname` to change the hostname. You can only change the UUID through the initial-startup script.

**Chassis** shows the chassis type, a model number, hardware version (where applicable), and the serial number.

**Chassis Environment** contains the base MAC address for all modules (for a chassis with multiple modules, the individual modules' MACs appear in `moduleinfo`), power status, fan status, and chassis temperature:

- **Power** can be “Online,” “Online Partial” (one power supply is working, the other is absent), or “Failed Partial” (one is working, the other failed).
- **Fan(setting)** shows the fan status and its speed setting. The fan status can be “Online,” “Not Present,” “Fault” (the fan tray failed), or “Ctr Fail” (the control to the fan-tray failed). The speed setting is in parentheses, and is “high,” “medium,” “low,” or “Unk” (unknown).
- The temperature setting(s) next are customized for certain chassis types:
  - **System Temp., CPU Temp. and CPU** show the ambient chassis temperature, the temperature of the CPU chip, and the current CPU speed. This appears only for the platforms that support both ambient and CPU temperature readings (such as the ARX-2500). The **System Temp** can be “Normal,” “Too high,” or “Failed” (temperature monitoring failed), followed by both temperatures in Celsius. The **CPU speed** is relevant because these chassis types automatically reduce the CPU speed if the temperature is too high. This shows the current CPU speed followed by an indication of whether or not the speed has been reduced; “(Normal)” means that the CPU is running at 100%, a percentage (such as “85%”) indicates that the CPU has been throttled back.
  - **Temperature** appears for other chassis types. This is the same as the **System Temp.** described above.

**Power Details** appears for the ARX-1500, ARX-2000, ARX-2500, and ARX-4000, which have redundant power supplies. This has one row for each power supply showing the power-supply state (“Online,” “Absent,” or “Failed”).

The ARX-1500 and ARX-2500 each have redundant power supplies, A and B. They are accessible from the back of the chassis, on the left side. Each power supply has a plug for its power cable.

The ARX-2000 also has redundant power supplies, 1/1 (on top) and 1/2 (under 1/1). They are accessible from the back of the chassis, on the right side. Each power supply has a plug for its power cable.

The ARX-4000 has redundant power supplies in both the control plane and the dataplane; these are numbered 1/1 and 1/2 for the control plane (in the top half of the chassis) and 2/1 and 2/2 for the data plane (on the bottom half). All power supplies are accessible from the back of the chassis, on the right side. Each power supply has a plug for its power cable.

**Guidelines: private-subnet** This shows the **VLAN** (where applicable; for example, the ARX-VE uses only VLAN 1 and the ARX-1500 and ARX-2500 have no private VLAN, so this does not appear for those platforms), **Subnet**, and **Subnet Mask** for the private subnet on this chassis. You set this when you install the switch. You can reset it with `ip private vlan` or `ip private subnet reassign`. This subnet must be unique for all switches in a Resilient Overlay Network (RON); see `ron tunnel` for more information about a RON.

---

**Guidelines: diskuse** The first three tables only appear for a chassis with replaceable disks (any platform except the ARX-500 or the ARX-VE). The **SATA Drive Details** table appears for the ARX-500. The **Disk Usage** table appears for all chassis types.

**Logical Disk Details** shows the status of the RAID as a single, logical disk.

**Disk** is always 1. This represents the single, logical disk comprised of the disks in the table below.

**Status** is “Optimal” (both disks are working), “Degraded” (one disk failed or is degraded), “Verifying *n%*” (someone issued the **raid verify** command to verify disk integrity; the percentage shows the progress of the verification test), or “Failed.”

**Verification Mode** is “Manual” or “Automatic,” as set by the **raid verification-mode** command.

**Verification Rate** is the percentage of CPU that the RAID can use for verifying a disk. You can change this for manual verifications with **raid verification-rate**.

**Disk Details** shows the location and size of each disk, disk state, the data-transfer rate, and the model number.

**Disk** indicates the location of the physical disk: Bay 1 is on top of Bay 2 in all chassis types with replaceable disks.

**Size** is the full capacity of the disk.

**State** is “Online,” “Degraded,” (the disk may fail soon), “Rebuild *n%*” (someone used **raid rebuild** to add the disk to the RAID; the percentage shows the progress of the rebuild), “Not Present,” “Failed,” or “Unknown.”

**Transfer Rate** is the current throughput on the disk’s bus channel. This is negotiated at startup between the disk controller and the disks themselves. The next table shows the maximum rate allowed by the controller.

**Model** is the specific model number of the disk drive.

**RAID Controller Details** displays the current RAID settings.

**Rebuild Rate** is the percentage of CPU that the RAID can use for rebuilding a disk. You can change this with **raid rebuild-rate**.

**Max Transfer Rate** is the maximum throughput allowed on the disk’s bus channel.

**Firmware** is firmware version running on the disk controller.

**RAID Alarm** is “Enabled” or “Disabled.” You can disable the alarm with the **raid silence** command.

**SATA Drive Details** appears for an ARX-500 with a Serial ATA (SATA) disk drive.

**Firmware** is firmware version running on the disk.

**Model** and

**Serial** identify the disk drive.

**Disk Usage** shows the switch’s software directories and their total space (in MB), used space (MB), free space (MB), and used percentage (%).

**Guidelines: slotinfo** Slot Environment, the only table in the slotinfo group, shows each slot's contents and status:

- **Slot** is the location of the module in the chassis. This is 1 (the control plane on the top half) or 2 (the data plane on the bottom) for the ARX-4000. It is always 1 for the ARX-500 or ARX-2000.
- **Type** is "ACM" (for the control plane on top) or "NSM" (for the data plane on the bottom) on the ARX-4000. For the ARX-500 or ARX-2000, the single slot contains an "ACM."
- **State** is the current state of the module. This is one of the module states documented for the [show version](#) command; see [Guidelines: Module States](#), on page 5-54.
- **Power** can be "Online," "Degraded," or "Failed."
- **Temperature** is the aggregate of all temperature-sensor readings in the module. This is either "Normal" or "Too High," along with the current temperature range on the module.
- **NVR Battery** appears for the NSM on the ARX-4000 or the ACM on the ARX-500 or ARX-2000. This is the battery status for Non-Volatile RAM (NVRAM). The possible values in this field are "Good," "Missing," "Charging," "Testing," "Degraded," or "Failed." The NVRAM stores transaction logs from the ACM, which are critical for failure recovery. The battery provides extra protection for these logs. Contact F5 Support if the status is "Missing," "Degraded," or "Failed;" you may need a battery upgrade.
- **Drive** appears only for the ACM. This shows the drive type (LSI, IDE, or SATA) and status for the internal disk(s). The possible status values are "Good," "Degraded," "Error," or "Unknown." If the status is "Degraded" or "Error," replace the drive (for an ARX-1500, ARX-2000, ARX-2500, or ARX-4000) and/or contact F5 personnel (for an ARX-500). An "Unknown" status would likely be caused by an error in the drive-detection software.

The ARX-VE has no hardware, so this option generates no output when you run it on that platform. This option also generates no output when you run it on the ARX-1500 or the ARX-2500.

**Guidelines: Port Media Details Table** Port Media Details only appears in the summary view (without any options) for the platforms that support 10G optics. These are the ARX-2500 and the ARX-4000. Each of these platforms supports up to two transceivers. Each row shows the following details about one of the transceivers:

**Slot/Port**, also identified on the front panel, identify the transceiver's port,

**Type**, is the particular transceiver model,

**Vendor** shows the manufacturer of the transceiver, and

**Status**, which is Good, Bad, Present, Not Present, Absent, or Unknown.

---

**Guidelines:** The VM Information table only appears for the ARX-VE, which is a Virtual Appliance (VA, which is similar to a VM):

**moduleinfo**

- vMAC Address** is the virtual MAC address assigned to the ARX-VE.
- Adapter** describes the network controller used by the ARX-VE.

**Module** is the heading for several tables with details of each module.

The first table describes the hardware in each module:

- Slot** is the module's slot number.
- Ports** is the number of ports on the module.
- Procs** is the number of processors.
- Card** is the card type: SCM\_40, NSM, NSM\_TX/FX, ASM/ASM\_FC, or ACM. This does not appear on the ARX-VE.
- Hardware** only appears for the ARX-VE. This describes the CPU and memory resources reserved for the ARX-VE.
- Xeon** is the CPU speed for all Xeon processors (used in every module except the NSM) and memory that is allocated to each Xeon processor. This does not appear on the ARX-VE.
- SiByte** is the CPU speed for all SiByte processors (used on the NSM and standalone ACMs) and the memory allocated to each SiByte complex. Each SiByte complex has two MIPS-processor cores. This does not appear for the ARX-VE, ARX-1500, or ARX-2500; none of these systems contain SiByte processors.
- Serial** is the module's serial number. This does not appear for the ARX-VE, ARX-1500, or ARX-2500; for those systems, refer to the overall chassis serial number in the `show chassis chassisinfo` output.

The second table shows the range of MAC addresses assigned to the module and its current hardware revision (the major-revision letter and minor-revision number, along with any Rework or Deviation on the module). For the ARX-1500 and ARX-2500, this shows the BIOS version. This table does not appear for the ARX-VE.

The final tables do not appear for the ARX-VE, ARX-1500, or ARX-2500.

The third table displays the revisions for the Complex Programmable Logic Devices (CPLDs) on the module, the **Reset CPLD**, the **Keeper CPLD**, the **Power CPLD** (ARX-4000 only), and the **MUX CPLD** (also ARX-4000 only):

- The **Reset CPLD** coordinates hardware resets when the chassis powers up.
- The **Keeper CPLD**, in conjunction with an FPGA, ensures that all client-transaction logs are stored safely in NVRAM before the chassis powers down.
- The **Power CPLD** (ARX-4000 only) coordinates the distribution of power from multiple power supplies to the chassis components.
- The **MUX CPLD** (ARX-4000 only) multiplexes status signals from various internal components and sends a unified signal to the NVR FPGA (described below). This also activates/deactivates various LEDs on the external panels.
- The **BIOS Version** appears for the control plane (or ACM) on the ARX-500 and the ARX-4000.

**Guidelines:** The next table shows versions for bootstrap, diagnostics, and boot-loader firmware.  
**moduleinfo (cont.)** These components manage the module's boot process: the bootstrap software starts the hardware, then the diagnostics run to verify the hardware functions, and finally the boot-loader loads and starts all of the system software. These come bundled with each software release; to install the versions that came with the latest release, use the [firmware upgrade](#) command.

The final table presents FPGA information, which varies from platform to platform:

ARX-4000 and ARX-2000 - the table contains the versions of the LBA FPGA and the NVR FPGA. The LBA (Load-Balancing Algorithm) FPGA merges inbound packets from the external interfaces to the NSM cores. The NVR FPGA manages the NVR, monitors chassis status through the MUX CPLD, and runs a watchdog process that reboots the chassis in the event of a serious failure.

ARX-500 - the versions for one FPGA and the boot-related firmware on the NSM processors. The FPGA is a hybrid of the NVR and MTL FPGAs.

**Guidelines:** Temperature Details shows temperature-sensor information from each module.

**temperature** For the ARX-1500 and ARX-2500, the table shows the following fields:

Slot is always "1."

Module is always "ACM."

System Temp. shows the ambient chassis temperature in Celsius.

CPU Temp. shows the temperature of the CPU chip in Celsius.

CPU shows the current CPU speed. These chassis types automatically reduce the CPU speed if the temperature is too high. This field shows the current CPU speed followed by an indication of whether or not the speed has been reduced; "(Normal)" means that the CPU is running at 100%, a percentage (such as "85%") indicates that the CPU has been throttled back.

Fan Status shows the fan status and its speed setting. The fan status can be "Online," "Not Present," "Fault" (the fan tray failed), or "Ctr Fail" (the control to the fan-tray failed). The speed setting is in parentheses, and is "high," "medium," "low," or "Unk" (unknown).

For all other hardware platforms, each processor has one temperature sensor positioned near the processor. The sensor takes its own "local" reading for the ambient temperature of the processor, and it takes a "remote" reading from the processor itself. The remote reading is the temperature of the processor's silica.

---

**Guidelines: metalog** Metalog Usage shows the statistics for metalog usage on this chassis.

Status is the status of the metalog driver software, which writes metalog packets to an internal NFS export and duplicates them to a twin driver in the redundant peer (if there is one). The possible options are “Standalone” (there is no redundant peer), “Active” (the driver is duplicating all metalog packets to the redundant peer), and “Standby” (the driver is receiving all metalog packets from the Active peer).

Statistics is a table with metalog-usage statistics:

I/O Count is the number of metalog packets sent to local storage (and remote storage, if this is the Active chassis in a redundant pair).

Retransmit Count only increments on the Active peer in a redundant pair. This is the number of metalog transmissions to the Standby peer that required a retry.

Hourly Latency (usecs) is the average latency in micro-seconds between the ARX and its local metalog storage. This number is updated once per hour. On the “Active” peer, this is the longer of two events that occur in parallel: writing the data to the local partition and writing the same data to the Standby peer’s partition.

You can use [show metalog usage](#) to show all of the hourly metalog statistics since the last ARX reboot. The [clear metalog usage](#) command clears these statistics and restarts them at 0 (zero).

This output only appears on a chassis with an internal metalog driver, but namespace software keeps metalog read/write statistics on all chassis types. On any platform, you can use the [show statistics metalog](#) command to see these read/write statistics from a namespace perspective.

**Guidelines: NVR** The NVR table shows the following information about the state of the hardware that protects Non-Volatile RAM:

NVR Battery is the battery status for Non-Volatile RAM (NVR or NVRAM). The possible values in this field are “Good,” “Missing,” “Charging,” “Testing,” “Degraded,” or “Failed.” The NVRAM stores transaction logs from the control plane, called *metalog* data, which are critical for failure recovery. The battery provides extra protection for these logs in the event of a power outage.

ECC State is the state of the Error-Correction Circuitry (ECC). The ECC checks all data as it is read from NVRAM, and generates errors if it detects any corruption. This can be “No Error,” “Pending,” “Non-Correctable Error,” or “Unknown.” A “Non-Correctable Error” state is serious; contact F5 personnel if you see this.

NVR Size (MB) is the size of the NVRAM region, in MegaBytes.

The ARX-VE has no NVRAM hardware, so this option generates no output when you run it on that platform. The `nvr` option does not even appear on the ARX-1500 and ARX-2500, which also do not support NVRAM hardware.

**Samples** [Figure 5.1 on page 5-26](#), [Figure 5.2 on page 5-27](#), [Figure 5.3 on page 5-30](#), [Figure 5.4 on page 5-31](#), [Figure 5.5 on page 5-31](#), and [Figure 5.6 on page 5-33](#) show sample output for the `show chassis` command on the ARX-4000, ARX-2500, ARX-1500, ARX-VE, ARX-2000, and ARX-500 respectively.

## show clock

**Purpose** Use the `show clock` command to see the current time/date setting on the ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show clock`

**Guidelines** The ARX has a separate clock in each module, synchronized internally through NTP. The clock display is from the ACM, which has the master clock for all processes in the switch.

Use the [clock set](#) command to reset the clock. Use the [clock timezone](#) command to reset the time zone. Use the [ntp server](#) command to synchronize the clock with an external NTP server.

### Sample

```
stoweA# show clock
 Local time: Mon 03 Nov 2008 01:48:45 AM EST -0500 America New_York
 Universal time: Mon 03 Nov 2008 06:48:45 AM UTC
```

**Related Commands** [clock set](#)  
[clock timezone](#)  
[ntp server](#)

## show hostname

**Purpose** Use the `show hostname` command to see the ARX's hostname.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show hostname`

**Guidelines** To set the hostname, use the cfg-mode [hostname](#) command.

**Sample**

```
bstnA(cfg)# show hostname
bstnA
bstnA(cfg)#
```

**Related Commands** [hostname](#)

---

# show memory usage

**Purpose** The show memory usage command shows usage statistics for ARX memory.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** show memory usage [report]

**report** (optional) causes the CLI to create a report instead of showing output on the command line. The CLI shows the report name after you type the command. The report is named “memory\_usage\_yyyymmddHHMMSS.rpt,” where yyyymmddHHMMSS is the date and time when the report was created. Use [show reports](#) to list all reports and view the report’s contents.

**Platforms** ARX-1500 and ARX-2500

**Guidelines** The output contains a table with 3-hour samples of memory usage, where the most-recent sample is at the top. Every row of the table shows the memory usage for one 3-hour sample:

**Date**

MM/DD is the month and day of the 3-hour sample.

**Time Interval** is the start time and end time for the 3-hour sample.

**%Memory** shows the low, average (Avg), and high percentages of memory used during the sample period.

Use the [show processors usage](#) command to show similar statistics for all processors on the switch; for other platform types, such as the ARX-2000, this also includes memory-usage statistics. The [show system tasks](#) command shows the currently-running tasks on one or more processors.

**Samples** stoweA# show memory usage  
shows the memory-usage statistics for all processors on an ARX-2500. See [Figure 5.7 on page 5-38](#) for sample output.

canbyA# show memory usage report

Scheduling report: memory\_usage\_201103220344.rpt  
canbyA#

sends the processor-usage statistics for an ARX-1500 to a report. See [Figure 5.8 on page 5-38](#) for a sample report.

**Related Commands** [show processors usage](#)  
[show system tasks](#)

*Figure 5.7 Sample Output: show memory usage*

# show metalog usage

**Purpose** Namespace software and network software each record important log information, called *metalog* data, to be shared with the ARX device's redundant peer. This metalog data facilitates a failover from the active ARX to its backup ARX. The ARX-1500 and ARX-2500 each store this data on internal disk partitions, one partition per volume group plus one partition per fastpath processor. The `show metalog usage` command shows usage statistics for these metalog-storage partitions.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show metalog usage [report]`

**report** (optional) causes the CLI to create a report instead of showing output on the command line. The CLI shows the report name after you type the command. The report is named "metalog\_usage\_yyyymmddHHMMSS.rpt," where *yyyymmddHHMMSS* is the date and time when the report was created. Use [show reports](#) to list all reports and view the report's contents.

**Valid Platforms** ARX-1500 and ARX-2500

**Guidelines** The output contains one table per metalog partition. At the top of each table is the following label:

Metalog Usage for Disk Partition *id* used by {Volume-Group *n* | Fastpath *slot.proc*}

Where

- Disk Partition *id* shows the ID of the internal-disk partition to store this metalog data.
- Volume-Group *n* is the volume group that stores its metalog information on partition *id*. The [show volume-group](#) command lists all volume groups on the chassis.
- Fastpath *slot.proc* indicates that the fastpath (or network) processor at *slot.proc* is using this internal partition to store its metalog data. The [show processors](#) command lists all processors on the chassis and shows which of them run the Fastpath (network) processes.

**Guidelines (Cont.)** Each table shows 1-hour samples of memory usage, where the oldest sample is at the top. Every row of the table shows the metalog-partition usage for a single one-hour sample:

**Date** is the month and day of the sample.

**Time Interval** is the start time and end time for the sample.

**I/O Count** is the number of metalog packets sent to the local partition. If this ARX is in a redundant pair, this is the sum of the packets sent to the local partition and the duplicate packets sent to the partition on the backup peer. You can use the [show redundancy](#) command to check the redundancy status of this chassis.

**Retransmit Count** only increments on the active peer in a redundant pair. This is the number of metalog transmissions to the backup peer that required a retry.

**Latency (usecs)** is the minimum, maximum, and average latency in micro-seconds between the ARX and its local metalog partition. These numbers are updated once per hour. On the active peer in a redundant pair, this is the longer of two events that occur in parallel: writing the data to the local partition and writing the same data to the backup peer's partition.

The ARX keeps these statistics from the most-recent time it has booted. You can use the [clear metalog usage](#) command to clear these statistics immediately.

The [show redundancy metalog](#) command shows similar statistics, but it applies to all platforms (except the ARX-VE). To find similar statistics on the ARX-VE platform, use the [probe metalog latency](#) command.

On all platforms, the namespace software keeps metalog read/write statistics. You can use the [show statistics metalog](#) command to see these metalog-usage statistics from a namespace-software perspective.

**Samples** stoweA# [show metalog usage](#)  
shows the metalog-usage statistics for all processors on an ARX-2500. See [Figure 5.9 on page 5-41](#) for sample output.

canbyA# [show metalog usage report](#)

Scheduling report: metalog\_usage\_201104110152.rpt  
canbyA#

sends the metalog-usage statistics for an ARX-1500 to a report. See [Figure 5.10 on page 5-41](#) for a sample report.

**Related Commands** [clear metalog usage](#)  
[show processors](#)

---

## show processors

**Purpose** Use the `show processors` command to list the processors (CPUs) installed on the ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show processors`

**Guidelines: Output on the ARX-1500, ARX-2500, and ARX-VE** The ARX-1500 and ARX-2500 use a multi-core processor, where each core is primarily dedicated to either network (fastpath) processing, storage (volume-group) processing, or CLI/GUI (system-management) processing. The output for this command shows two tables to describe the current state of these processor cores.

The first table shows the role and CPU usage of each core, where each core appears on a separate row. The ARX-1500 uses fewer cores than the ARX-2500, and the ARX-VE has one:

**Proc** is in *processor.core* format. The *processor* is always 1, and the *core* number identifies the particular core.

**Role** is either “Fastpath” (network processing), “Volume-Group” (storage-related processing), or “System” (CLI, GUI, and other management processing). This indicates the type of process that primarily runs on this core.

**CPU1M** is the average CPU usage over the last 60 seconds. This number is a percentage.

**CPU5M** is the average CPU usage over the last 5 minutes. As above, this is a percentage.

The second table shows a summary for the entire processor. This table only appears on the ARX-1500 and ARX-2500:

**Up Time** is time since the last reboot. You can use the [reload](#) command to manually reboot. For the ARX-VE, you can also reboot from your VM-client console.

**Memory (MB)** is a heading for the following processor-memory measures, in MegaBytes:

- **Total** is the processor’s total memory.
- **Free** is the processor’s available memory.

**Swap (MB)** is a heading for similar swap-space measures, also in MegaBytes. This is space on the internal hard disk that is used as a memory region when free memory is low:

- **Total** is the processor’s total swap space.
- **Free** is the processor’s available swap space.

**Guidelines: Output on Other Platforms** For the other platforms (not the ARX-1500, ARX-2500, or ARX-VE), the output is a table with one row per processor. Each row contains the following fields:

**Proc** shows the slot location of the processor in *slot.processor* format. Processor 1.1 is the management processor for all platforms.

**Module** is the processor’s module type (ACM only on the ARX-500 or ARX-2000; ACM or NSM on the ARX-4000).

State is the current processor state:

- Up
- Reset - should appear very briefly, just before Boot.
- Boot - the processor is running its diagnostic tests, invoked during boot.
- Init - the processor passed its diagnostic tests and is being provisioned.
- Waiting - the processor is waiting for configuration parameters before it can begin processing. If all NSM and/or ACM processors are in the “Waiting” state, they require proper configuration for the interfaces. Minimally, each interface must be started with no [shutdown \(cfg-if-gig\)](#), and each NSM processor requires a proxy-IP address (see [ip proxy-address](#)).
- Downloading - if (during “Init”) the processor discovers that it needs new software, it enters this state to fetch and install the software.
- Unknown - the CLI cannot ascertain the processor’s state.
- Standby - appears for an NSM processor that failed over to a peer processor and then came back online. The peer processor is now handling this processor’s traffic, and this processor is in a hot-standby state. If the peer processor fails, this processor takes control. The [nsm recovery](#) command configures the NSM processors to go into this state if they experience a failure. NSM processors also go into this state after a full-chassis failover (you prepare an ARX for failovers with the [redundancy](#) command).
- Failed
- FW Upgrade - indicates that the module is upgrading its firmware. You can start a firmware upgrade after installing a software release with new firmware; see the documentation for the [firmware upgrade](#) command.
- FW Upgrade Failed - means that the module failed an attempted firmware upgrade. Call F5 Support if you see this state.

Up Time is time since the last reboot. Use the [reload](#) command to reboot.

Memory (MB) is a heading for the following processor-memory measures, in MegaBytes:

- Total is the processor’s total memory.
- Free is the processor’s available memory.

CPU1M is the current CPU usage in a 1-minute period.

CPU5M is the current CPU usage in a 5-minute period.

**Guidelines: Related  
Commands**

Use the [show system tasks](#) command to view the tasks that are currently running on one or more processors. For statistics on CPU and memory usage over time, use the [show processors usage](#) command.

- Samples**
- stoweA> show processors**  
shows the processors on an ARX-2500. See [Figure 5.11 on page 5-45](#) for sample output.
- stkbngA# show processors**  
shows the processors on an ARX-VE. See [Figure 5.12 on page 5-45](#) for sample output.
- bstnA# show processors**  
shows the processors on an ARX-4000. See [Figure 5.13 on page 5-46](#) for sample output.
- prtIndA# show processors**  
shows the processors on an ARX-2000. See [Figure 5.14 on page 5-46](#).

---

# show processors usage

**Purpose** The `show processors usage` command shows usage statistics for the processors (CPUs) installed on the ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show processors usage`  
`show processors usage {slot.processor | all} [report]`

*slot.processor* (optional) specifies one processor.

*slot* is the slot number.

*processor* is the processor number. Use the [show processors](#) command to show all processors and their associated *slot.processor* IDs.

**all** (optional) specifies all processors.

**report** (optional) is only an option if you select one processor or use the **all** keyword. This causes the CLI to create a report instead of showing output on the command line. The CLI shows the report name after you type the command. The report is named “processor\_usage\_yyyymmddHHMMSS.rpt,” where *yyyymmddHHMMSS* is the date and time when the report was created. Use [show reports](#) to list all reports and view the report’s contents.

**Guidelines** The output contains a table for each chosen processor. Each table shows 3-hour samples of CPU usage, with the most-recent sample at the top. The tables are labeled as follows:

Processor Usage for *slot.proc* appears for each processor on most platforms, and

Processor Usage for *slot.proc role* appears instead on the ARX-1500 and ARX-2500. The *role* describes the types of processes that used the CPU cycles in the table:

- **FastPath** is for network-related processes, similar to those that run on the NSM in other platforms. These are also called *data plane* processes.
- **Volume-Group** is for storage-related processes, such as managed-volume processes and the policy engine.
- **System** is for the CLI and GUI (or manager) processes, and other processes related to system administration.

**Guidelines (Cont.)** Every row of the table shows the CPU usage for one 3-hour sample:

**Date** is the month and day of the 3-hour sample.

**Time Interval** is the start time and end time for the 3-hour sample.

**%CPU** shows the low, average (Avg), and high percentages of CPU cycles used during the sample period.

**%Memory** shows the same measures for memory. This does not appear in the output for the ARX-1500 or ARX-2500; you can use [show memory usage](#) to get these measures on either of those platforms.

**%Swap** shows the percentages for swap-space usage. An ACM only uses swap space when a large portion of standard memory is used up. On the ARX-1500 and ARX-2500, this command omits the %Swap table.

Use the [show processors](#) command to show the current state of all processors on the switch. The [show system tasks](#) command shows the currently-running tasks on one or more processors.

**Samples** `bstnA# show processors usage`  
shows the processor-usage statistics for all processors on an ARX-4000. See [Figure 5.15 on page 5-48](#) for sample output.

`canbyA# show processors usage`  
shows the processor-usage statistics for all processors on an ARX-1500. See [Figure 5.16 on page 5-50](#) for sample output.

`bstnA# show processors usage 1.1 report`  
Scheduling report: processor\_usage\_201104010144.rpt  
sends the processor-usage statistics to a report. See [Figure 5.17 on page 5-51](#) for a sample report.

**Related Commands** [show processors](#)

## show uptime

**Purpose** Use the `show uptime` command to see how long the system has been “up” since the last reboot.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show uptime`

**Guidelines** This command displays the length of time since the last reboot in weeks, days, hours, and minutes, as shown in the sample below.

**Sample**  
`bstnA> show uptime`  
`bstnA uptime is 0 weeks, 0 days, 0 hours, 27 minutes.`

**Related Commands** [show processors](#)  
[show version](#)

| <b>Purpose</b>                                | Use the <code>show version</code> command to display the installed-software versions and a summary of the chassis' configuration and state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Mode</b>                                   | (any)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Security Role(s)</b>                       | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Syntax</b>                                 | <code>show version</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Guidelines: Release Table</b>              | <p>Running Release is the software version that is currently running. This appears in the following format:</p> <pre>release-file : Version version-num (build-date) username</pre> <p>where <i>release-file</i> is in the local "releases" directory, which you can see with the <a href="#">show releases</a> command.</p> <p>Armed Release is the software to be loaded on the next reboot, if any. This appears in the same format as the Running Release. Use <a href="#">boot system</a> to arm the switch with a new release file. Use <a href="#">reload</a> to reboot and put the new release file into service.</p> <p>Backup Release is the software release that was running prior to the current release, if any. F5 personnel can roll the switch back to this release if needed.</p>                                                                                                                                                                      |
| <b>Guidelines: System Configuration Table</b> | <p>System Configuration is a table of module information for the hardware platforms, one row per module.</p> <p>Slot is only 1 for all chassis except the ARX-4000, which has a second slot devoted to data-plane processes.</p> <p>Admin is "enabled."</p> <p>ModuleType is ACM (which runs management processes, control-plane processes, and possibly data-plane processes) or NSM (which exclusively runs data-plane processes).</p> <p>ModuleState values appear in <i>Guidelines: Module States</i>, below.</p> <p>FW Upgrade is "enabled" or "disabled." If enabled, a chassis-software upgrade automatically upgrades the module's firmware. To enable this feature, contact F5 personnel. To install firmware manually, after a software upgrade, use the <a href="#">firmware upgrade</a> command.</p> <p>For the ARX-VE, ARX-1500, and ARX-2500, the System Configuration table contains a single row showing how long it has been since the last reboot.</p> |
| <b>Guidelines: Resource Table</b>             | <p>The Resource table only appears for the ARX-500, ARX-2000, or ARX-4000 platforms. This table shows the high-level state of the switch, and whether it supports packet forwarding (like a MAC bridge) or not (like an end station).</p> <p>State is "Up" or an error message. If there is an error, use <a href="#">show chassis</a> for details.</p> <p>Forwarding is "Enabled" (meaning the ARX can forward packets from one client/server port to another, performing the functions of a MAC bridge) or "Disabled." You can set this with the <a href="#">switch-forwarding enable</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                 |

- Guidelines: Module States** The ModuleState field can contain any of the following values:
- Online
  - Empty
  - Removed - the slot previously had a module, but it has been removed.
  - Discovery - the chassis is finding all module states, very early in the boot process.
  - Boot - the module is running its diagnostic tests, invoked during boot.
  - Init - the module passed its diagnostic tests and is provisioning its internal processors.
  - Downloading - if (during “Init”) the module discovers that it needs new software, it enters this state to fetch and install the software.
  - Online Partial - at least one processor is up, but not all of them are online yet. If a processor does not come up after 5 minutes, this changes to “Failed Partial” state.
  - Failed Partial - at least one processor is up, but at least one processor failed.
  - Failed
  - Offline - applies to the network processors. This indicates that the ACM has not provided the network processors with important configuration parameters, so the processors cannot come online. Any of the following issues can result in this state on an ARX-500, ARX-2000, or ARX-4000:
    - The NVRAM battery failed on the ACM. Use `show chassis nvr` to confirm this; if the issue persists, contact F5 Support.
    - The NVRAM is not up yet. As above, you should contact F5 Support if the NVRAM issue persists.
  - Poweroff - the slot has no power.
  - FW Upgrade - the module is installing new firmware from the installed software release. The `firmware upgrade` command starts a firmware installation.
  - FW Upgrade Failed - a `firmware upgrade` failed on this module.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>shutdown</code> command to halt the ARX, perhaps from a remote location. This gracefully stops all power on the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Guidelines</b>       | <p>This command prepares the ARX for a planned power outage. After you run this command on one of the hardware platforms, you have up to 72 hours before the battery drains for the Non-Volatile RAM (NVRAM). The NVRAM is memory on the ACM that stores all database transactions for the namespace processes; if the processes fail, they can recover by replaying these transactions. This is called <i>metalog</i> data. A managed volume requires its metalog data when it starts up.</p> <p>You must manually power on the chassis to restore it to service. If you restore power after the NVRAM battery drains, all of the managed volumes on the ARX must re-import.</p> <p>The CLI warns you that you must manually restore power to the chassis; enter <b>yes</b> to proceed with the power-off sequence. You can restore power on site by flipping the power switch or pushing the power button. Refer to the Hardware Installation Guide for your chassis to find the location of the power button or switch. The ARX-VE is a software-only platform that runs as a Virtual Appliance (VA, similar to a VM); use your VM client to restart the ARX-VE.</p> <p>The ARX-VE has no NVRAM hardware, and stores its metalog data in one of the hypervisor's disk partitions. A re-import of managed volumes is therefore unnecessary for the ARX-VE, no matter how long it is shut down. (The same is true of the ARX-1500 and ARX-2500, which store their metalog data on their internal disk drives.)</p> <p>You can use the <code>reload</code> command to reboot the ARX. To clear the NVRAM (in case of an unrecoverable corruption), use <code>clear nvr</code>.</p> |
| <b>Sample</b>           | <pre>provB# shutdown  This command turns off the chassis and powers it down. You will need to manually restore power to return the chassis to service. Are you sure? [yes/no] yes       shuts down an ARX named "provB."</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

---

## RAID Management

---

---

This chapter contains an alphabetical list of commands for managing the redundant array of independent disks (RAID) in the ARX chassis.

# raid offline

**Purpose** Use the `raid offline` command to set a disk drive offline in the switch chassis.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `raid offline { disk1 | disk2 }`

**Valid Platforms** ARX-2000 and ARX-4000

**Guidelines** After issuing the command, enter the `show chassis diskuse` command to verify changes and to view disk status.

## ◆ Note

The following sample output shows the disk and raid details from the `show chassis diskuse` command. See [Figure 5.1 on page 5-26](#) and [Figure 5.6 on page 5-33](#) for complete `show chassis` output samples.

## Sample

```
bstnA# raid offline disk1
Set disk drive in Bay 1 offline ? [yes/no] yes
bstnA# show chassis diskuse
```

### Logical Disk Details:

| Disk | Status  | Verification Mode | Verification Rate |
|------|---------|-------------------|-------------------|
| 1    | Optimal | Manual            | 50 %              |

### Disk Details:

| Disk  | Size    | State   | Transfer Rate | Model       |
|-------|---------|---------|---------------|-------------|
| Bay 1 | 136.73G | Online  | 3.0Gb/sec     | ST3146855SS |
| Bay 2 | 136.73G | Offline | 3.0Gb/sec     | ST3146855SS |

### RAID Controller Details:

| Rebuild Rate | Max Transfer Rate | Firmware   | RAID Alarm |
|--------------|-------------------|------------|------------|
| 85 %         | 3.0Gb/sec         | 7.0.1-0061 | Enabled    |

### Disk Usage:

| Name                   | Total MB | Used MB | Free MB | Used% |
|------------------------|----------|---------|---------|-------|
| System                 | 2331     | 1408    | 804     | 64%   |
| Releases               | 5285     | 2687    | 2328    | 54%   |
| Logs                   | 54951    | 87      | 52071   | 1%    |
| Cores; DiagInfo; Lists | 21133    | 219     | 19840   | 2%    |
| Scripts                | 3172     | 59      | 2951    | 2%    |
| Reports                | 8458     | 35      | 7992    | 1%    |

[show chassis](#)

## raid rebuild

**Purpose** Use this command to rebuild a RAID configuration on a disk in the switch chassis.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `raid rebuild { disk1 | disk2 }`

**disk1** is the drive in Bay 1

**disk2** is the drive in Bay 2

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** This command is required after installing a disk, so that it can rejoin the RAID.

This process slows down various internal processes, so we recommend running it on the backup peer in a redundant pair (see [redundancy](#) for information on redundant pairs).

The ARX-1500 and ARX-2500 write their metalog data to the RAID, and managed-volume performance is affected if these writes are slowed. Those platforms write all of their metalog data both to the active peer and the backup peer at the same time, so a `raid rebuild` on the backup peer still affects managed-volume processing on the active peer. For the ARX-1500 and ARX-2500, we recommend performing the rebuild during off hours only. You can use the `show metalog usage` command to view usage statistics for the metalog driver.

After issuing the command, enter the `show chassis diskuse` command to verify the change and to view the rebuild progress.

### Sample

```
bstnA# raid rebuild disk1
bstnA# show chassis diskuse
```

#### Logical Disk Details:

| Disk | Status  | Verification Mode | Verification Rate |
|------|---------|-------------------|-------------------|
| 1    | Optimal | Manual            | 50 %              |

#### Disk Details:

| Disk  | Size    | State       | Transfer Rate | Model       |
|-------|---------|-------------|---------------|-------------|
| Bay 1 | 136.73G | Rebuild 22% | 3.0Gb/sec     | ST3146855SS |
| Bay 2 | 136.73G | Online      | 3.0Gb/sec     | ST3146855SS |

#### RAID Controller Details:

| Rebuild Rate | Max Transfer Rate | Firmware   | RAID Alarm |
|--------------|-------------------|------------|------------|
| 85 %         | 3.0Gb/sec         | 7.0.1-0061 | Enabled    |

#### Disk Usage:

| Name   | Total MB | Used MB | Free MB | Used% |
|--------|----------|---------|---------|-------|
| System | 2331     | 1408    | 804     | 64%   |

## raid rebuild-rate

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | This command specifies how much of the system's RAID-controller resources to use in rebuilding the RAID.                                                                                                                                                                                                                                                                                                                              |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>           | <b>raid rebuild-rate <i>rate</i></b><br><br><i>rate</i> (1-99) is the percentage of the system's RAID controller, an internal CPU used for managing access to the internal disks. A higher number ensures a faster rebuild, but slower disk access during the rebuild.                                                                                                                                                                |
| <b>Default(s)</b>       | 90                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Valid Platforms</b>  | ARX-1500, ARX-2000, ARX-2500, and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Guidelines</b>       | The CLI and the GUI access the internal disks for many operations, as do several processes that create reports. Whenever a <a href="#">raid rebuild</a> occurs, this command determines the division of RAID-controller cycles between these disk-access operations and the RAID-rebuild operation. After issuing the command, enter the <a href="#">show chassis diskuse</a> command to verify changes and to view the rebuild rate. |
| <b>Sample</b>           | <pre>bstnA(cfg)# raid rebuild-rate 85</pre> sets the RAID-rebuild rate to 85% of the RAID-controller's time. This leaves 15% of the controller's cycles to manage disk I/O operations, such as recording the running configuration or writing reports.                                                                                                                                                                                |
| <b>Related Commands</b> | <a href="#">raid rebuild</a><br><a href="#">show chassis diskuse</a>                                                                                                                                                                                                                                                                                                                                                                  |

## raid silence

**Purpose** Use this command to silence the audible RAID alarm. Use the no form to re-activate the alarm.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** **raid silence**  
**no raid silence**

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** The RAID subsystem sounds an alarm on disk failure. Use [show chassis](#) to find the disk drive that failed. Replace the failed disk as instructed in the [ARX®-4000 Hardware Installation Guide](#), the [ARX®-2000 Hardware Installation Guide](#), or the instructions that come with the replacement disk.

Use this command to silence the alarm while you replace the drive. Once done, re-enable the alarm with **no raid silence**.

**Samples** bstnA# **raid silence**  
silences the alarm.

bstnA# **no raid silence**  
reactivates a silenced alarm.

**Related Commands** [show chassis](#)

## raid verification-mode

- Purpose** Use the `raid verification-mode` command to determine whether or not the RAID verification test runs automatically.
- Mode** `cfg`
- Security Role(s)** `network-engineer` or `crypto-officer`
- Syntax** `raid verification-mode manual`  
`raid verification-mode automatic [at start every {num days | day-of-week}]`
- `at start every {num days | day-of-week}` (optional) is only available on the ARX-1500 and ARX-2500.
- start* is the scheduled start time for verifications to run each day. The time is in the following format:
- HH:MM[:00]***
- where the only possible value for seconds is “00.”
- every *num days*** (optional) chooses some number of days between automatic verifications. We recommend a *num* of 1, so that the verifications run daily.
- every *day-of-week*** (optional) chooses a single day of the week to run automatic verifications. The options are “sunday,” “monday,” “tuesday,” and so on. This makes the automatic verifications run weekly instead of daily; it is not generally recommended.
- Default(s)** `automatic`  
`at 23:00 every 1 days`  
on ARX-1500 and ARX-2500 only. On all other platforms, automatic verification is continuous.
- Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000
- Guidelines** The verification test checks the integrity of every block on each disk. Whenever a bad block is found, the test attempts to replace it with its counterpart on the other disk. The verification fails if any block is corrupted on both disks. It also checks the disk controller for errors.
- If the verification mode is manual, you can use the [raid verification-rate](#) command to determine the CPU cycles used by the verification process. If the verification mode is automatic, the verification rate is set by a system default: on the ARX-1500 and ARX-2500, it runs once at 11PM (see below); on all other chassis types, it runs continuously, every 5 minutes.
- Whether or not the verification mode is manual, you can use the [raid verify](#) command to run the verification manually.
- After issuing the command, you can use the [show chassis diskuse](#) command to verify the change.

**Guidelines: Use Manual Verification for the ARX-1500 and ARX-2500**

The ARX-1500 and ARX-2500 write their metalog data to the RAID, and managed-volume performance is affected if these writes are slowed. Constant, automatic RAID verification may have an adverse effect on storage processing for those platforms. For the ARX-1500 and ARX-2500, we recommend using the `at` option with `raid verification-mode automatic`, and choose a schedule that runs verifications during slow business hours. If you choose `automatic` on these platforms, the verification runs daily at 11PM by default.

You can use the `show metalog usage` command to monitor the internal metalog driver's usage of the RAID.

**Samples**

```
bstnA# raid verification-mode manual
bstnA# show chassis diskuse
```

Logical Disk Details:

| Disk | Status  | Verification Mode | Verification Rate |
|------|---------|-------------------|-------------------|
| 1    | Optimal | Manual            | 50 %              |

Disk Details:

| Disk  | Size    | State  | Transfer Rate | Model       |
|-------|---------|--------|---------------|-------------|
| Bay 1 | 136.73G | Online | 3.0Gb/sec     | ST3146855SS |
| Bay 2 | 136.73G | Online | 3.0Gb/sec     | ST3146855SS |

RAID Controller Details:

| Rebuild Rate | Max Transfer Rate | Firmware   | RAID Alarm |
|--------------|-------------------|------------|------------|
| 85 %         | 3.0Gb/sec         | 7.0.1-0061 | Enabled    |

Disk Usage:

| Name                   | Total MB | Used MB | Free MB | Used% |
|------------------------|----------|---------|---------|-------|
| System                 | 2331     | 1408    | 804     | 64%   |
| Releases               | 5285     | 2687    | 2328    | 54%   |
| Logs                   | 54951    | 87      | 52071   | 1%    |
| Cores; DiagInfo; Lists | 21133    | 219     | 19840   | 2%    |
| Scripts                | 3172     | 59      | 2951    | 2%    |
| Reports                | 8458     | 35      | 7992    | 1%    |

sets manual verification in the "bstnA" ARX.

```
stoweA# raid verification-mode automatic at 02:00:00 every 1 days
```

sets automatic verification in the "stoweA" ARX, an ARX-2500, and schedules the verification for 2 AM every morning. This is a best practice for the ARX-1500 and ARX-2500, where the RAID verifications may slow the performance of managed volumes.

|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | This command specifies how much of the system's RAID-controller resources to use in verifying the integrity of the RAID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Valid Platforms</b>  | ARX-1500, ARX-2000, ARX-2500, and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Guidelines</b>       | <p>The RAID controller is a separate CPU from the CPUs used for data-plane (network) processing or control-plane processing. This controller is used for the internal disks, and runs when the internal disks are used. The system uses the internal disks for the various <b>copy</b> commands (such as <b>copy ftp</b>) and <b>move</b> commands (such as <b>move ... ftp</b>). This CPU is also required when internal processes write to their log files (see <b>show logs</b>), create reports (see <b>show reports</b>), write packet-capture files (see <b>capture session</b>), <b>collect</b> diagnostic information and put it into a local file, or otherwise write to the internal disks.</p> <p>You cannot change the default for automatic verification tests. These run continuously on the system; a higher rate would degrade system performance. This command changes the RAID-controller percentage used for <i>manual</i> (user-invoked) verification tests. You can stop the test from running automatically with the <b>raid verification-mode manual</b> command, and then use the <b>raid verify</b> command to manually run the test.</p> <p>The verification test checks the integrity of every block on each disk. Whenever it finds a bad block, it attempts to replace the block with its twin block on the other disk. The verification fails if any block is corrupted on both disks. The test also checks the RAID controller for errors.</p> <p>After issuing this command, enter the <b>show chassis diskuse</b> command to verify the change.</p> |

**Sample**

```
bstnA# raid verification-rate 50
bstnA# show chassis diskuse
```

## Logical Disk Details:

| Disk | Status  | Verification Mode | Verification Rate |
|------|---------|-------------------|-------------------|
| 1    | Optimal | Manual            | 50 %              |

## Disk Details:

| Disk  | Size    | State  | Transfer Rate | Model       |
|-------|---------|--------|---------------|-------------|
| Bay 1 | 136.73G | Online | 3.0Gb/sec     | ST3146855SS |
| Bay 2 | 136.73G | Online | 3.0Gb/sec     | ST3146855SS |

## RAID Controller Details:

| Rebuild Rate | Max Transfer Rate | Firmware   | RAID Alarm |
|--------------|-------------------|------------|------------|
| 85 %         | 3.0Gb/sec         | 7.0.1-0061 | Enabled    |

## Disk Usage:

| Name                   | Total MB | Used MB | Free MB | Used% |
|------------------------|----------|---------|---------|-------|
| System                 | 2331     | 1408    | 804     | 64%   |
| Releases               | 5285     | 2687    | 2328    | 54%   |
| Logs                   | 54951    | 87      | 52071   | 1%    |
| Cores; DiagInfo; Lists | 21133    | 219     | 19840   | 2%    |
| Scripts                | 3172     | 59      | 2951    | 2%    |
| Reports                | 8458     | 35      | 7992    | 1%    |

| <b>Purpose</b>          | This command invokes a verification test for both disks in the RAID. Use the <code>no</code> form of the command, <code>no raid verify</code> , to stop a RAID verification that is currently in progress.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Default(s)</b>       | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Valid Platforms</b>  | ARX-1500, ARX-2000, ARX-2500, and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Guidelines</b>       | <p>You cannot use this command while another RAID-verify operation is running, and another RAID-verify operation is frequently running when the <code>raid verification-mode</code> command is at its default (<code>automatic</code>). The <code>show chassis diskuse</code> command shows the current mode, manual or automatic. Use <code>raid verification-mode manual</code> to allow manual verification at any time, and guarantee that no RAID-verify process is running in the background. You can also use <code>no raid verify</code> to cancel the current RAID-verify operation, whether it was invoked automatically or manually.</p> <p>The verification test checks the integrity of every block on each disk. Whenever it finds a bad block, it attempts to replace the block with its twin block on the other disk. The verification fails if any block is corrupted on both disks. The test also checks the disk controller for errors.</p> <p>After issuing the command, enter the <code>show chassis diskuse</code> command to view the progress of the test, and its final results. Refer to the Status of the Logical Disk (that is, the full RAID), in the first table of the output. The test takes more than one hour. If the verification fails, you can replace one or both disks as instructed in the <a href="#">ARX®-4000 Hardware Installation Guide</a>, the <a href="#">ARX®-2000 Hardware Installation Guide</a>, or in the instructions that come with the replacement disk.</p> |

---

### Sample

```
bstnA# raid verify
```

```
% INFO: RAID verification has started.
```

```
bstnA# show chassis diskuse
```

#### Logical Disk Details:

| Disk | Status        | Verification Mode | Verification Rate |
|------|---------------|-------------------|-------------------|
| 1    | Verifying 17% | Manual            | 50 %              |

#### Disk Details:

| Disk  | Size    | State  | Transfer Rate | Model       |
|-------|---------|--------|---------------|-------------|
| Bay 1 | 136.73G | Online | 3.0Gb/sec     | ST3146855SS |
| Bay 2 | 136.73G | Online | 3.0Gb/sec     | ST3146855SS |

#### RAID Controller Details:

| Rebuild Rate | Max Transfer Rate | Firmware   | RAID Alarm |
|--------------|-------------------|------------|------------|
| 85 %         | 3.0Gb/sec         | 7.0.1-0061 | Enabled    |

#### Disk Usage:

| Name                   | Total MB | Used MB | Free MB | Used% |
|------------------------|----------|---------|---------|-------|
| System                 | 2331     | 1408    | 804     | 64%   |
| Releases               | 5285     | 2687    | 2328    | 54%   |
| Logs                   | 54951    | 87      | 52071   | 1%    |
| Cores; DiagInfo; Lists | 21133    | 219     | 19840   | 2%    |
| Scripts                | 3172     | 59      | 2951    | 2%    |
| Reports                | 8458     | 35      | 7992    | 1%    |

|-------------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <b>at</b> command to schedule a CLI command or script to run at a later time.                    |
| <b>Mode</b>             | cfg                                                                                                      |
| <b>Security Role(s)</b> | crypto-officer                                                                                           |
| <b>Syntax</b>           | <b>at</b> <i>start</i> [ <i>every interval</i> ] <b>do</b> <i>action</i> [ <i>report report-prefix</i> ] |

is the high-level syntax for this command.

*start* is the scheduled start time. This cannot be in the past unless you specify the optional **date** (below) and use **every interval** to run the job regularly. It breaks down into the following format:

**[date mm/dd/yyyy] HH:MM[:00]**

- *mm/dd/yyyy* (optional) specifies a date (for example, 01/07/2005 for January 7, 2005).
- **HH:MM[:00]** is the hours and minutes on a 24-hour clock (for example, 04:00 means 4AM). The only possible value for seconds is “00.”

**every interval** (optional) creates a regular interval at which the CLI jobs run. This breaks down into one of two formats:

**every count** {minutes | hours | days | weeks | months}

- **count** (1-4,294,967,295) is the number of minutes, hours, days, etc. between CLI runs. For example, **every 10 minutes** or **every 6 months**.
- **minutes | ... months** is a required choice.

**every** {sunday | monday | tuesday | ... | saturday}

creates a weekly interval that runs on the given day of the week.

**do action** is required. The **action** is either a CLI command or a directive to run a script:

**do cli-command** | **do run cli-script**

- **cli-command** (1-255 characters) is a valid CLI command. Surround this with quotation marks if it contains any spaces. For example, **do “show cifs-service user-sessions all”**.
- **cli-script** (1-255 characters) identifies a script of CLI commands in the `scripts` directory. Use the `show scripts` command for a full listing of available scripts.

**report report-prefix** (optional, 1-255 characters) creates a report for the scheduled job. The report is named as follows:

*report-prefix\_yyyymmddHHMM.rpt*, where *report-prefix* is chosen here, *yyyy* is the year of the scheduled run, *mm* is the month, *dd* is the day, *HH* is the hour, and *MM* is the minute. Each run of the CLI job generates a report (if you specify an interval with the **every** option), so the date makes it possible to differentiate multiple reports for the same job.

- Default(s)** **every *interval*** - none; the CLI command or script runs only once.  
**report *report-prefix*** - none; the **at** command does not generate a report (though the command itself may generate one).
- Guidelines** The CLI displays the scheduled execution time after you enter this command. Use [show at](#) to view all pending CLI jobs. You can remove a job from the schedule with the [clear at](#) command.  
To run a script immediately, you can use the [run](#) command. To download a CLI-script file from an FTP, SCP, or TFTP site, use the [copy](#) command. You can use [expect monitor](#) to repeat any show command until a certain string appears in its output.
- Samples** `bstnA(cfg)# at 01:06 every 5 minutes do "show sessions" report adminSessions`  
The scheduled execution time for AT job ID '1' is: 8/26/10 1:06 AM  
runs the [show sessions](#) command every 5 minutes. Each run generates a report with the prefix, "adminSessions." See [Figure 7.1](#) for a sample report.  
`bstnA(cfg)# at 10:30:00 do "expect show firewall timeout 30"`  
The scheduled execution time for AT job ID '2' is: 12/6/05 10:30 AM.  
runs the [expect show firewall](#) command at 10:30 in the morning, once only.  
`bstnA(cfg)# at date 05/05/2011 03:45:00 every 1 days do "active-directory update forest medarch.org proxy-user acoProxy2"`  
The scheduled execution time for AT job ID '3' is: 5/5/11 3:45 AM.  
runs the [active-directory update forest](#) command at 3:45 AM, daily.

```

---

## clear at

**Purpose** Every time someone uses the [at](#) command, one CLI job is added to the command schedule. Use the **clear at** command to remove one CLI job from this schedule, or to remove all of them.

**Mode** priv-exec

**Security Role(s)** crypto-officer

**Syntax** **clear at** [*job-id*]

*job-id* (optional, 1-2,147,483,647) identifies a specific CLI job to clear. If you omit this, the command clears all CLI jobs. Use the [show at](#) command for a list of all scheduled CLI jobs, with their job IDs.

**Default(s)** clear all scheduled CLI jobs if no *job-id* is used.

**Guidelines** If you clear all scheduled jobs, the CLI prompts for confirmation. Enter **yes** to proceed.

Use the [at](#) command to schedule a CLI command (or script) to run in the future, once or periodically. Use [show at](#) to view all pending CLI jobs.

**Samples**

```
bstnA# clear at
Remove all 2 jobs from the command scheduler? [yes/no] yes
bstnA#
clears all scheduled CLI jobs.
```

```
bstnA# clear at 3
removes one scheduled CLI job, with job ID 3.
```

**Related Commands** [at](#)  
[show at](#)

## copy ftp

**Purpose** Use the `copy ftp` command to transfer a file (such as a software-release file or a log file) to or from the ARX via FTP.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`  
(A backup-operator can copy reports.)

**Syntax: Download to the Switch** `copy ftp://[user[:password]@]server/source-file dir file`

`ftp://[user[:password]@]server/source-file` (1-1024 characters) is the URL for the source file:

`user[:password]@` (optional) are the credentials for FTP access. If you omit them, they default to the credentials set by the `ip ftp-user` command. If you omit the password, the CLI prompts for one.

`server` is the IP address or hostname for the FTP server.

`source-file` is the source-file path. Lead with an extra slash (“/”) if the path is absolute (for example, “ftp://10.1.1.5//var/rels/aco4665.rel”). Use only one slash if the path is local to the home directory for `user` (for example, “ftp://10.1.1.5/basic\_ns.scr”). This conforms with the specification for FTP URLs in RFC 1738. You cannot use wildcards (such as \*).

`dir` is the destination directory. Choose one of the following: `configs`, `scripts`, `license`, or `releases`.

`file` (1-1024 characters) is the name you choose for the copy.

**Syntax: Upload** `copy directory file ftp://[user:password@]server/dest-path [format {text|report|csv|xml}]`

`directory` is one of the following: `logs`, `stats-logs`, `cores`, `configs`, `replicated-configs`, `reports`, `diag-info`, `software`, `scripts`, `capture`, or `license`.

`file` (1-1024 characters) identifies the source file from the above directory. You can use wildcards (such as \*) to select multiple files.

`ftp://[user:password@]server/dest-path` (1-1024 characters) is the URL for the destination directory or file (see above).

`format {text|report|csv|xml}` (optional) applies to the “reports” directory only. This chooses the output format for the external copy of the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.

**Default(s)** `user:password` from the URL - the default set by `ip ftp-user`.

---

**Guidelines** If you enter a user name without a password, the CLI prompts for the password before continuing. Enter the password for the *user* you included in the URL.

Use [copy scp](#) to upload or download over a secure connection, using SCP. The [copy tftp](#) command uses TFTP (Trivial FTP) as a transport. To send out a file as an E-mail attachment, use [copy smtp](#). The [copy {nfs|cifs}](#) command transfers files between the maintenance directories on the ARX and its client-accessible volumes.

For a download to the local disks, you can use [show directories directory-name](#) to verify that the copy was successful.

To move a file from the local disk to an FTP server, thereby removing it from the local disk, you can use the [move ... ftp](#) command.

To manage local files, use [delete](#) and/or [rename](#). To view ASCII files, use [show directory file-name](#), [tail](#), and/or [grep](#).

**Guidelines:** For copies from the reports directory, you can reformat the copy to XML or CSV (comma-separated value) format. Use a .xml or .csv extension for the *destination-file-name*, and the copy assumes the chosen format. A .txt or .rpt extension leaves the destination file in plain-text format.

**Reformatting Reports to XML or CSV**

**Guidelines: Wildcards** You can use several wildcard characters to select multiple source-file names for an upload:

- \* matches any string, including an empty string.
- ? matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `copy logs traplog.? ftp ...` would fail, but `copy logs "traplog.?" ftp ...` would succeed.
- [] surrounds a class of characters (for example, [abcz]), and matches any one of the characters inside the square brackets (a, b, c, or z).
- [a-z] matches any single character from the range a through z (all lower-case).

**Samples** `bstnA# copy ftp://jpublic@arxftp.f5.com/rel6.0.rel releases rel6.0.rel`  
Password: `jpassword`

downloads a release file, rel6.0.rel, from the FTP server at arxftp.f5.com.

`bstnA# copy logs syslog ftp://noc.phredco.com/syslog-switch10`

uploads the syslog to the FTP server at noc.phredco.com. This example uses the default username and password, set by [ip ftp-user](#).

You can use wildcards (such as *, ?, or [a-z]) to select multiple files; see the <i>Guidelines: Wildcards</i> below.</p> <p><b>directory</b> is the destination directory. Choose one of the following: <b>configs</b>, <b>scripts</b>, <b>license</b>, or <b>releases</b>.</p> <p><b>file</b> (1-255 characters) is the name you choose for the copy. If you copy a file into the <b>releases</b> directory, its extension must be “.rel” (for example, “lastestRelease.rel”).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax: From Switch to Volume</b> | <p><b>copy directory file {nfs cifs} namespace vol [dest-file-path] [format {text report csv xml}]</b></p> <p><b>directory</b> is one of the following: <b>logs</b>, <b>stats-logs</b>, <b>cores</b>, <b>configs</b>, <b>replicated-configs</b>, <b>reports</b>, <b>diag-info</b>, <b>software</b>, <b>scripts</b>, <b>capture</b>, or <b>license</b>.</p> <p><b>file</b> (1-1024 characters) identifies the source file from the above directory. As above, you can use wildcards (such as *) to specify multiple files.</p> <p><b>nfs   cifs</b> is a required choice. This chooses the protocol for the file transfer.</p> <p><b>namespace</b> (1-30 characters) identifies the namespace to hold the copy.</p> <p><b>vol</b> (1-1024 characters) is the volume to hold the copy.</p> <p><b>dest-file-path</b> (optional, 1-1024 characters) is the path to the destination file, starting at the volume root. If you omit this, the destination file appears in the volume root, and has the same name as the source file.</p> <p><b>format {text report csv xml}</b> (optional) applies to the “reports” directory only. This chooses the output format for the external copy of the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.</p> |
| <b>Default(s)</b>                    | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Guidelines** This command is useful on a site that prohibits FTP access to the datacenter, or otherwise restricts network connections between the ARX and the Internet. You can go to a host in the client network to access the Internet, download a desired file to an ARX volume, and then use this `copy` command to copy the file into an ARX directory. For example, you could use this method to download a new release file from <https://downloads.f5.com/esd/productlines.jsp> and then copy it to the “releases” directory.

The CLI chooses a user identity based on the transfer protocol. For NFS, the CLI uses `root` as its identity. For CIFS, the CLI uses the `proxy-user (gbl-ns)` for the chosen namespace. These identities typically ensure that there are no permissions problems during the copy operation.

There are several alternative options for the `copy` command that access the network directly. The `copy ftp` command copies files over an FTP connection to or from a remote server. Use `copy scp` to upload or download over a secure connection, using SCP. The `copy tftp` command uses TFTP (Trivial FTP) as a transport. To send out a file as an E-mail attachment, use `copy smtp`.

For a download to the local disks, you can use `show directories directory-name` to verify that the copy was successful.

To move a file from the local disks to a ARX volume, thereby deleting it from the local disk, you can use the `move ... {nfs|cifs}` command.

To manage local files, use `delete` and/or `rename`. To view ASCII files, use `show directory file-name, tail`, and/or `grep`.

**Guidelines: Wildcards** You can use several wildcard characters to select multiple file names:

- `*` matches any string, including an empty string.
- `?` matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `copy logs traplog.? cifs insur /claims` would fail, but `copy logs “traplog.?” cifs insur /claims` would succeed.
- `[]` surrounds a class of characters (for example, `[abcz]`), and matches any one of the characters inside the square brackets (a, b, c, or z).
- `[a-z]` matches any single character from the range a through z (all lower-case).

**Samples** `bstnA# copy cifs medarcv /rcrds/maint/ 11658.rel releases latest.rel`  
copies a release file, 11658.rel, from a directory in the “medarcv~/rcrds” volume. After the copy is complete, this command sequence could go on to load this release (with `boot system` and `reload`).

`bstnA# copy logs syslog* nfs wwmed /acct/.admin/`  
copies all syslog files from the local “logs” directory to a hidden directory in “wwmed~/acct,” an NFS volume.

Choose <b>configs</b> or <b>scripts</b>.</p> <p><i>dest-file</i> (optional, 1-1024 characters) is the name of the remote file. The CLI ignores this if you used wildcards to select multiple files.</p> |
| <b>Default(s)</b>                             | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Guidelines** This copy operation uses the `ip ron-user` credentials at the remote switch, or the current `user` credentials if no such RON user is defined. If the administrative account is not defined at the remote switch, or if it is defined with a different password, the copy operation fails.

The file transfer is encrypted and sent with the Secure Copy (SCP) protocol.

There are several other copy commands for copying files to or from other servers, or for copying to or from a client-accessible volume on the current switch. Use `copy ftp` or `copy tftp` to upload or download using FTP or TFTP. To copy a file to or from an SCP server in your network, use `copy scp`. To send out a file as an E-mail attachment, use `copy smtp`. The `copy {nfs|cifs}` command transfers files between the maintenance directories on the ARX and its client-accessible volumes.

After a download to the local disks, you can use `show directories directory-name` to verify that the copy was successful.

To manage local files, use `delete` and/or `rename`. To view ASCII files, use `show directory file-name`, `tail`, and/or `grep`.

**Guidelines: Wildcards** You can use several wildcard characters to select multiple source-file names for an upload:

- `*` matches any string, including an empty string.
- `?` matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `copy scripts homeDir.? ron ...` would fail, but `copy scripts "homeDir.?" ron ...` would succeed.
- `[]` surrounds a class of characters (for example, `[abcz]`), and matches any one of the characters inside the square brackets (a, b, c, or z).
- `[a-z]` matches any single character from the range a through z (all lower-case).

**Samples** `bstnA# copy ron prtlnA scripts setupUsrShr.scr scripts setup.scr`  
downloads a script, `setupUsrShr.scr`, from a remote ARX named "prtlnA."

`provA# copy configs test.rcfg ron newptA configs test2.rcfg`  
sends a replicated-config file to a remote ARX named "newptA."

**Related Commands** `ip ron-user`  
`copy ftp`  
`copy tftp`  
`copy scp`  
`copy smtp`  
`copy {nfs|cifs}`  
`delete`  
`rename`  
`grep`  
`tail`  
`show directories`

---

## copy scp

|                                       |                                                                                                                                            |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                        | Use the <code>copy scp</code> command to securely copy a file (such as a software-release file or a log file) to or from the ARX over SCP. |
| <b>Mode</b>                           | priv-exec                                                                                                                                  |
| <b>Security Role(s)</b>               | network-technician, network-engineer, storage-engineer, or crypto-officer<br>(A backup-operator can copy reports.)                         |
| <b>Syntax: Download to the Switch</b> | <b><code>copy scp://[user@]server:source-file directory file [accept-host-key]</code></b>                                                  |

`scp://[user@]server:source-file` (1-1024 characters) is the URL for the source file:

`user@` (optional if someone created an [ip scp-user](#)) is the username to present to the other end of the SCP connection. This user must be valid at the remote host. If you omit this and an [ip scp-user](#) is defined, it defaults to the username set by that command.

`server:` is the IP address or hostname for the SCP host. End with a colon (:).

`source-file` is the source-file path. Lead with a slash (“/”) if the path is absolute (for example, “`scp://root@10.1.1.5:/var/rels/aco4665.rel`”). Use no slash if the path is local to the home directory for `user` (for example, “`scp://root@10.1.1.5:basic_ns.scr`”).

`directory` is the destination directory. Choose one of the following: **configs**, **scripts**, **license**, or **releases**.

`file` (1-1024 characters) is the name you choose for the local copy.

**accept-host-key** (optional) indicates that if the other end of the connection has an unknown SSH host key (that is, if it is new, or if its key has changed since the last time the host was contacted), the ARX should accept the new host key and continue with the download. Otherwise, the ARX stops the download if the host presents an unknown key.

|                       |                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax: Upload</b> | <b><code>copy directory file scp://[user@]server:dest-path [accept-host-key] [format {text report csv xml}]</code></b> |
|-----------------------|------------------------------------------------------------------------------------------------------------------------|

`directory` is one of the following: **logs**, **stats-logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

`file` (1-1024 characters) identifies the source file from the above directory. You can use wildcards (such as \*, ?, or [a-z]) to select multiple files; see the *Guidelines: Wildcards* below.

`scp://[user@]server:dest-path` (1-1024 characters) is the URL for the destination.

**accept-host-key** (optional) means to accept an unknown SSH host key from the remote host, if it presents one.

**format {text|report|csv|xml}** (optional) applies to the “reports” directory only. This chooses the output format for the external copy of the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.

**Default(s)** None

**Guidelines** If you enter a user name without a password, the CLI prompts you for a password after you issue this command. Enter the password for the *user* in the URL. The file is transferred over SCP, which uses a secure, encrypted connection to the remote host. Every host identifies itself with an encrypted SSH key. Whenever the ARX transfers a file using SCP, it exchanges keys with the remote host. If the remote-host key is different from one received previously, the host may not be the one you intended; an attacker may be posing as the intended host. For this reason, the ARX does not download or upload to a host with an unknown key unless you raise the **accept-host-key** flag. Note that the first contact with any server will require this flag to succeed.

The ARX deletes all SSH host keys on reboot, so all remote hosts are again unknown when the switch comes back up.

Use [copy ftp](#) or [copy tftp](#) to upload or download using FTP or TFTP. To send out a file as an E-mail attachment, use [copy smtp](#). The [copy {nfs|cifs}](#) command transfers files between the maintenance directories on the ARX and its client-accessible volumes.

After a download to the local disks, you can use [show directories](#) *directory-name* to verify that the copy was successful.

To move a file from the local disk to an SCP server, thereby removing it from the local disk, you can use the [move ... scp](#) command.

To manage local files, use [delete](#) and/or [move](#). To view ASCII files, use [show](#) *directory file-name*, [tail](#), and/or [grep](#).

**Guidelines: Wildcards** You can use several wildcard characters to select multiple source-file names for an upload:

- \* matches any string, including an empty string.
- ? matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `copy logs syslog.? scp ...` would fail, but `copy logs "syslog.?" scp ...` would succeed.
- [] surrounds a class of characters (for example, [abcz]), and matches any one of the characters inside the square brackets (a, b, c, or z).
- [a-z] matches any single character from the range a through z (all lower-case).

**Samples** `bstnA# copy scp://jpublic@myserver:rel2.0.rel releases r2.0.rel`  
Password: *password-for-jpublic*  
downloads a release file, rel2.0.rel, from jpublic's home directory at the host named "myserver."

`bstnA# copy logs syslog scp://noc:/var/logs/acolog10 accept-host-key`  
uploads the syslog to a host named "noc," using a default username and password. If the host key has changed for noc (or this is the first SCP to or from noc), the switch accepts the key and continues the upload.

**Related Commands** [ip scp-user](#)  
[copy ftp](#)  
[copy tftp](#)  
[copy smtp](#)  
[copy {nfs/cifs}](#)  
[move ... scp](#)  
[delete](#)  
[move](#)  
[grep](#)  
[tail](#)  
[show directories](#)

## copy smtp

**Purpose** Use the `copy smtp` command to send a maintenance file (such as a software-release file or a log file) as an E-mail attachment. This syntax only supports uploads from the switch.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer  
(A backup-operator can copy reports, but no other type of file.)

**Syntax** `copy directory file smtp://[e-mail-address]/destination-file  
[format {text|report|csv|xml}]`

*directory* is one of the following: **logs**, **stats-logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

*file* (1-1024 characters) identifies the source file from the above directory, such as a log file or a report. You can use wildcards (such as \*, ?, or [a-z]) to select multiple files; see the *Guidelines: Wildcards* below. Each matching file results in a separate E-mail message.

`smtp://[e-mail-address]/destination-file` (1-1024 characters) is an E-mail destination for the file:

`smtp://` is required. This declares that the destination is an E-mail address.

*e-mail-address* (optional) is the recipient of the E-mail in *username@host* format (for example, “jsmith@myco.com”). If you omit this, the CLI uses the default address set by the `cfg-smtp to` command.

*destination-file* is the name of the copy. If you used wildcards to select multiple files, this is the prefix for each copy. Each copy is sent as an attachment to the outbound E-mail message.

`format {text|report|csv|xml}` (optional) applies to the “reports” directory only. This chooses the output format for the external copy of the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.

**Default(s)** the destination E-mail address defaults to the one set by the `to` command

**Guidelines** DNS lookups must be configured for SMTP to function (see the documentation for [ip name-server](#)).

Use `copy ftp`, `copy tftp`, or `copy scp` to upload or download using FTP, TFTP, or SCP. The `copy {nfs|cifs}` command transfers files between the maintenance directories on the ARX and its client-accessible volumes.

To manage local files, use `delete` and/or `move`. To view ASCII files, use `show directory file-name`, `tail`, and/or `grep`.

- 
- Guidelines: Wildcards** You can use several wildcard characters to select multiple source-file names for an upload:
- \* matches any string, including an empty string.
  - ? matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `copy logs syslog.? smtp ...` would fail, but `copy logs "syslog.?" smtp ...` would succeed.
  - [] surrounds a class of characters (for example, [abcz]), and matches any one of the characters inside the square brackets (a, b, c, or z).
  - [a-z] matches any single character from the range a through z (all lower-case).

**Samples** `bstnA# copy logs syslog smtp://juser@wwmed.com/syslog`  
sends a copy of the syslog to “juser@wwmed.com.” The ARX sends the syslog as an attachment to a brief E-mail message.

`bstnA# copy reports metadata_only.17.rpt smtp://juser@wwmed.com/mdo.csv`  
sends a copy of a report to the same E-mail recipient. This command reformats the attachment into CSV before sending it (note the “.csv” extension on the destination file name).

**Related Commands** [copy ftp](#)  
[copy tftp](#)  
[copy scp](#)  
[copy {nfs|cifs}](#)  
[delete](#)  
[move](#)  
[grep](#)  
[tail](#)  
[show directories](#)

## copy tftp

**Purpose** Use the `copy tftp` command to transfer a file (such as a software-release file or a log file) to or from the ARX via TFTP.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`  
(A backup-operator can upload reports to a remote host.)

**Syntax: Download to the ARX** `copy tftp://server/source-file directory file`

`tftp://server/source-file` (1-1024 characters) is the URL for the source file:

`server` is the IP address or hostname for the TFTP server.

`source-file` is the source-file path. Lead with an extra slash (“/”) if the path is absolute (for example, “tftp://10.1.1.5//var/rels/aco4665.rel”). Use only one slash if the path is local to the “tftpboot” directory. This conforms with the specification for FTP URLs in RFC 1738.

`directory` is the destination directory. Choose one of the following: **configs**, **scripts**, **license**, or **releases**.

`file` (1-255 characters) is the name you choose for the copy.

**Syntax: Upload** `copy directory file tftp://server/dest-file  
[format {text|report|csv|xml}]`

`directory` is one of the following: **logs**, **stats-logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

`file` (1-1024 characters) identifies the source file from the above directory. You can use wildcards (such as \*, ?, or [a-z]) to select multiple files; see the *Guidelines: Wildcards* below.

`tftp://server/dest-file` (1-1024 characters) is the URL for the destination file (see above).

`format {text|report|csv|xml}` (optional) applies to the “reports” directory only. This chooses the output format for the external copy of the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.

**Default(s)** `None`

---

**Guidelines** Use [copy scp](#) to upload or download over a secure connection, using SCP. Use [copy ftp](#) to upload or download using FTP. To send out a file as an E-mail attachment, use [copy smtp](#). The [copy {nfs|cifs}](#) command transfers files between the maintenance directories on the ARX and its client-accessible volumes.

After a copy to the local disks, you can use [show directories](#) `directory-name` to verify that the copy was successful.

To move a file from the local disk to a TFTP server, thereby removing it from the local disk, you can use the [move ... tftp](#) command.

To manage local files, use [delete](#) and/or [rename](#). To view ASCII files, use [show](#) `directory file-name`, [tail](#), and/or [grep](#).

**Guidelines: Wildcards** You can use several wildcard characters to select multiple source-file names for an upload:

- `*` matches any string, including an empty string.
- `?` matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `copy capture nas?.cap tftp ...` would fail, but `copy logs "nas?.cap" tftp ...` would succeed.
- `[]` surrounds a class of characters (for example, `[abcz]`), and matches any one of the characters inside the square brackets (a, b, c, or z).
- `[a-z]` matches any single character from the range a through z (all lower-case).

**Sample** `bstnA# copy tftp://tftp.f5.com/rel6.0.rel releases r6.0.rel`  
downloads a release file, `rel6.0.rel`, from the TFTP server at `tftp.f5.com`.

**Related Commands** [copy ftp](#)  
[copy scp](#)  
[copy smtp](#)  
[copy {nfs|cifs}](#)  
[move ... tftp](#)  
[delete](#)  
[rename](#)  
[grep](#)  
[tail](#)  
[show directories](#)

## delete

**Purpose** The ARX contains directories for software-release files, log files, core files, report files, diagnostic information, and other maintenance files. Use the **delete** command to delete all files from a specified directory or to delete a specified file.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** **delete** {releases | logs | cores | reports | diag-info | scripts | capture} [*file-name*]  
**delete** {configs | license} *file-name*

**releases** | ... | **capture** identifies the directory. This is a required choice.

**file-name** (1-1024 characters) identifies a file to delete from the above directory. This is optional for any directory except **configs** or **license**; if you omit it for one of the other directories, the command deletes all files in the chosen directory. You can also use wildcards for those directories (such as \*, ?, or [a-z]); see the *Guidelines: Wildcards* below.

Some files in the **configs** and **license** directories are required for system operation and/or reboot recovery, so you cannot delete all files (or use wildcards) in those directories. You must specify a file to delete.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before deleting any files; enter **yes** to delete the file(s).

You cannot delete the running-release, armed-release, or backup-release file. You also cannot delete the “active.license” file in the license directory; removing the active license disables all storage services, so it is not recommended. (You can use [clear active-license](#) if you have been advised to remove the active license.) Do not delete core files unless advised to do so by F5 personnel; these files contain valuable data for diagnosing software problems.

The [show directories](#) command displays a listing of all directories on the ARX. Use the [grep](#), [rename](#), [copy](#), and [delete](#) commands to maintain these files.

**Guidelines: Wildcards** You can use several wildcard characters to select multiple file names:

- \* matches any string, including an empty string.
- ? matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, **delete logs traplog.?** would fail, but **delete logs “traplog.?”** would succeed.
- [] surrounds a class of characters (for example, [abcz]), and matches any one of the characters inside the square brackets (a, b, c, or z).
- [a-z] matches any single character from the range a through z (all lower-case).

---

**Samples**    `bstnA# delete logs syslog5.log`  
Delete file 'syslog5.log' in directory 'logs'? [yes/no] **yes**  
              deletes the file named "syslog5.log" from the logs directory.

`bstnA# delete logs syslog*`  
Delete file 'syslog' in directory 'logs'? [yes/no/all] **yes**  
Delete file 'syslog.1' in directory 'logs'? [yes/no/all] **all**  
`bstnA#`  
              deletes all syslog files from the logs directory.

`bstnA# delete cores`  
Delete all core files in directory 'cores'? [yes/no] **yes**  
              deletes all files in the cores directory.

**Related Commands**    [copy ftp](#)  
                          [copy scp](#)  
                          [copy tftp](#)  
                          [copy {nfs/cifs}](#)  
                          [grep](#)  
                          [rename](#)  
                          [show directories](#)

## grep

**Purpose** The ARX contains directories for software-release files, log files, core files, and other maintenance files. Use the **grep** command to filter one of these files, displaying the lines that match a pattern or text string.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax: One File** `grep filter {releases | logs | stats-logs | cores | configs | replicated-configs | reports | software | scripts | capture | license} file-name [ ignore ignore ] [ tail lines ]`

searches through one file.

*filter* (1-255 characters) is the pattern or text string to search for in the file. See the *Guidelines: Regular Expression* below for the syntax. The grep displays all lines containing this pattern.

**releases** | ... | **license** selects the directory. This is a required choice.

*file-name* (1-1024 characters) identifies the file to read.

**ignore** (optional) filters out text, and

*ignore* (1-1024 characters) specifies a text string to ignore.

**tail** (optional) displays the end of the file, and

*lines* (1-1024) specifies how many lines to show at the end of the file.

**Syntax: Directory** `grep filter {releases | logs | stats-logs | cores | configs | replicated-configs | reports | software | scripts | capture | license} [ ignore ignore ] [ tail lines ]`

searches through all files in a directory.

*filter* (1-255 characters) is the pattern or text string to search for in the directory. See the *Guidelines: Regular Expression* below for the syntax. The grep displays all lines from all files containing this pattern.

**releases** | ... | **license** selects the directory. This is a required choice.

**ignore** (optional) filters out text, and

*ignore* (1-1024 characters) specifies a text string to ignore.

**tail** (optional) displays the end of the file, and

*lines* (1-1024) specifies the number of lines to show.

**Default(s)** None

---

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Guidelines: Regular Expression</b> | <p>The regular expression syntax follows grep's "basic" regular-expression syntax:</p> <ul style="list-style-type: none"><li>. matches any single character.</li><li>.* matches any string, including the null string.</li><li>[...] matches any one of the enclosed characters.</li><li>[a-z] matches any character in the sorted range, a through z.</li><li>\ matches the next character, even if it has special meaning (for example, \. matches a period instead of any character).</li><li>[^...] matches any character that is <i>not</i> enclosed.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines: Available Files</b>    | <p>The <a href="#">show directories</a> command displays maintenance directories of the hard disks on the ARX. These are the directories and files you can search with the <code>grep</code> command. Use the <a href="#">move</a>, <a href="#">copy</a>, and <a href="#">delete</a> commands to maintain these files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Samples</b>                        | <pre>bstnA# grep :POLICY logs syslog</pre> <p>searches for the string ":POLICY" in the syslog. Sample output appears in <a href="#">Figure 7.2 on page 7-24</a>.</p> <pre>bstnA# grep :POLICY logs syslog ignore init</pre> <p>is the same search, but without any lines containing 'init.' Sample output appears in <a href="#">Figure 7.3 on page 7-24</a>.</p> <pre>bstnA# grep :POLICY.*\.\.\. logs syslog ignore init</pre> <p>searches for the same strings followed by an ellipses (...). Note the use of "\." Sample output appears in <a href="#">Figure 7.4 on page 7-24</a>.</p> <pre>bstnA# grep :POLICY.*\.\.\. logs syslog ignore init tail 5</pre> <p>is the same as the above example, but shows only the last 5 lines. Sample output appears in <a href="#">Figure 7.5 on page 7-24</a>.</p> <pre>prt1ndA# grep "prt1ndA.*CLI_COMMAND.*show namespace.*wmed" logs</pre> <p>Searches for certain CLI commands in the logs directory. All log files are searched. Sample output appears in <a href="#">Figure 7.6 on page 7-25</a>.</p> |
| <b>Related Commands</b>               | <ul style="list-style-type: none"><li><a href="#">copy ftp</a></li><li><a href="#">copy scp</a></li><li><a href="#">copy tftp</a></li><li><a href="#">copy {nfs cifs}</a></li><li><a href="#">copy smtp</a></li><li><a href="#">delete</a></li><li><a href="#">move</a></li><li><a href="#">move ... ftp</a></li><li><a href="#">move ... {nfs cifs}</a></li><li><a href="#">move ... scp</a></li><li><a href="#">move ... tftp</a></li><li><a href="#">show directories</a></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## ip ftp-user

**Purpose** When you use the `copy` or `move` command to transport files to/from an FTP site, you enter a username and password for the FTP server. Use the `ip ftp-user` command to set a default username and password.

Use the `no` form of this command to revert to the “anonymous” default.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip ftp-user name`  
`no ip ftp-user`

*name* (1-32 characters) is the FTP username.

**Default(s)** *name* - anonymous  
password - `upgrade-hostname`, where you can set the hostname with the `hostname` command.

**Guidelines** The CLI prompts twice for a password. See the sample below.  
This command makes the `copy ftp` and `move ... ftp` commands easier to use; you can omit the username and password from each of these commands, defaulting to this one.

**Sample**

```
bstnA(cfg)# ip ftp-user jsmith
Password: jpasswd
Validate Password: jpasswd
bstnA(cfg)# ...
```

provides a username and password, `jsmith` and `jpasswd`, for transferring files to/from an FTP server.

**Related Commands** `copy ftp`  
`move ... ftp`

---

## ip ron-user

**Purpose** When you use the [copy ron](#) command to copy a file onto another ARX, you require an administrative username and password for the remote peer. Use the `ip ron-user` command to set a default username and password.

Use the `no` form of this command to revert to using the current administrative account as the default.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip ron-user name`  
`no ip ron-user`

*name* (1-32 characters) is a valid administrative [user](#) at a remote ARX.

**Default(s)** If this is not set, the [copy ron](#) command uses the username and password of the current administrative account.

**Guidelines** The CLI prompts twice for a password. See the sample below.

**Sample** `bstnA(cfg)# ip ron-user jsmith`  
`Password: jpasswd`  
`Validate Password: jpasswd`  
`bstnA(cfg)# ...`

provides a username and password, `jsmith` and `jpasswd`, for sending file copies to a remote ARX.

**Related Commands** [copy ron](#)

## ip scp-user

**Purpose** When you use the `copy` or `move` command to transfer files to/from an SCP server, you enter a username and password for the SCP server. Use the `ip scp-user` command to set a default username and password for these operations.

Use the `no` form of this command to remove the default.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip scp-user name`  
`no ip scp-user`

*name* (1-32 characters) is a Unix username that is valid on the remote SCP server(s).

**Default(s)** None.

**Guidelines** The CLI prompts twice for a password. See the sample below.

This command makes the `copy scp` and `move ... scp` commands easier to use; you can omit the username and password from each command, defaulting to this one.

**Sample** `bstnA(cfg)# ip scp-user jsmith`  
`Password: jpasswd`  
`Validate Password: jpasswd`  
`bstnA(cfg)# ...`

provides a username and password, `jsmith` and `jpasswd`, for copying to/from an SCP server.

**Related Commands** `copy scp`  
`move ... scp`

---

## move

**Purpose** The ARX contains directories for software release files, log files, report files, and other maintenance files. Use the **move** command to change the name of a file in one of these directories.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** **move** {**logs** | **cores** | **configs** | **replicated-configs** | **diag-info** | **software** | **reports** | **scripts** | **capture** | **license**}  
*src-file-name dest-file-name*

**logs** | ... | **license** identifies the directory. This is required.

**logs** selects a log file. Use the [show logs](#) command for a full list of all available log files.

**cores** selects a core-dump file generated by a failing process. The [show cores](#) command lists all such files that currently exist, if any.

**configs** selects a configuration file, such as those generated by [copy running-config](#) and [copy global-config](#). Use [show configs](#) to list them.

**replicated-configs** selects a replicated-configuration file, from a remote ARX cluster. You can use these files for a disaster-recovery operation. Use [show replicated-configs](#) to list them.

**diag-info** selects a diagnostics file generated by [collect](#) or [collect logs](#). Use [show diag-info](#) to see if any are available.

**software** selects a software-related file or a software-user manual. The [show software](#) command lists all of them.

**reports** selects a report file.

**scripts** selects a script file. Use [show scripts](#) to see all available scripts.

**capture** selects a packet-capture file created by the [capture session](#) command. The [show capture](#) command lists all packet-capture files currently on the ARX.

**license** selects a license file. The [show license](#) command lists all license-related files currently on the ARX.

*src-file-name* (1-1024 characters) is the original file name, the file to rename.

*dest-file-name* (1-1024 characters) is the new name you choose for the file.

**Default(s)** None

**Guidelines** The [show directories](#) command displays all files and directories on the ARX hard disks.

You can also move files to an external servers. The [move ... ftp](#) command uploads over FTP, then deletes the source file after a successful copy operation. Use [move ... scp](#) to use a secure connection, SCP. The [move ... tftp](#) command uses TFTP (Trivial FTP) as a transport. The [move ... {nfs|cifs}](#) command transfers files from the maintenance directories on the ARX to its client-accessible volumes.

Use the [grep](#), [copy](#), and [delete](#) commands to maintain these files.

**Sample** `bstnA# move diag-info ns_wmed.tgz wmed_11_12.tgz`  
renames a diagnostics file.

**Related Commands** [move ... ftp](#)  
[move ... scp](#)  
[move ... tftp](#)  
[move ... {nfs/cifs}](#)  
[copy ftp](#)  
[copy scp](#)  
[copy tftp](#)  
[copy smtp](#)  
[copy {nfs/cifs}](#)  
[grep](#)  
[delete](#)  
[show directories](#)

---

## move ... ftp

**Purpose** Use the `move ... ftp` command to transfer a file (such as a core-dump file) off of the ARX via FTP. This command deletes the file after it is successfully copied, or leaves the file at the source location if the copy operation fails.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`  
(A backup-operator can move reports.)

**Syntax** `move directory file ftp://[user:password@]server/dest-file  
[format {text|report|csv|xml}]`

*directory* is one of the following: **logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

*file* (1-1024 characters) identifies the source file from the above directory.

`ftp://[user:password@]server/dest-file` (1-1024 characters) is the URL for the destination file:

`user[:password]@` (optional) are the credentials for FTP access. If you omit them, they default to the credentials set by the `ip ftp-user` command. If you omit the password, the CLI prompts for one.

*server* is the IP address or hostname for the FTP server.

*dest-file* is the new path that you want for the file. Lead with an extra slash (“/”) if the path is absolute (for example, “ftp://10.1.1.5//var/caps/arx0107.cap”). Use only one slash if the path is local to the home directory for *user* (for example, “ftp://10.1.1.5/gffstnA.tgz”). This conforms with the specification for FTP URLs in RFC 1738.

**format {text|report|csv|xml}** (optional) applies to the “reports” directory only. This chooses the output format for the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.

**Default(s)** `user:password` from the URL - the default set by `ip ftp-user`.

**Guidelines** If you enter a user name without a password, the CLI prompts for the password before continuing. Enter the password for the *user* you included in the URL.

To copy a file over FTP instead of moving it, you can use the `copy ftp` command.

You can also move (or copy) files using several additional protocols. Use `move ... scp` or `copy scp` to use an SCP connection for the move or copy operation. The `move ... tftp` and `copy tftp` commands use TFTP (Trivial FTP) as a transport. To send out a file as an E-mail attachment, use `copy smtp`. The `move ... {nfs|cifs}` and `copy {nfs|cifs}` commands transfer files between the maintenance directories on the ARX and its client-accessible volumes. To rename a file in its current ARX directory, you can use the `move` command.

The `move` commands only upload to an external server. The equivalent `copy` commands can also download. For example, the `copy ftp` command FTP-copies a file to or from the ARX.

To manage local files, use `delete` and/or `move`. To view ASCII files, use `show directory file-name`, `tail`, and/or `grep`.

**Guidelines:** For move operations out of the reports directory, you can reformat the file to XML or CSV (comma-separated value) format. Use a `.xml` or `.csv` extension for the *destination-file-name*, and the move operation converts the file to the chosen format. A `.txt` or `.rpt` extension leaves the file in plain-text format.

**Sample** `bstnA# move capture fsrvr.cap ftp://noc.phredco.com/bstnA_fsrvr.cap`  
moves a packet-capture file off of the ARX and onto the FTP server at `noc.phredco.com`. This example uses the default username and password, set by `ip ftp-user`.

**Related Commands** `ip ftp-user`  
`move`  
`move ... scp`  
`move ... tftp`  
`move ... {nfs|cifs}`  
`copy ftp`  
`copy scp`  
`copy tftp`  
`copy smtp`  
`copy {nfs|cifs}`  
`delete`  
`grep`  
`tail`  
`show directories`

---

## move ... {nfs|cifs}

**Purpose** Use the `move ... {nfs|cifs}` command to transfer a file (such as a software-release file or a log file) from the ARX to one of its volumes. This command deletes the file after it is successfully copied to the volume, or leaves the file at the source location if the copy operation fails.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer  
(A backup-operator can move reports.)

**Syntax** `move directory file {nfs|cifs} namespace vol [dest-file-path]  
[format {text|report|csv|xml}]`

*directory* is one of the following: **logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

*file* (1-1024 characters) identifies the source file from the above directory. You can use wildcards (such as \*, ?, or [a-z]) to select multiple files; see the *Guidelines: Wildcards* below.

**nfs** | **cifs** is a required choice. This chooses the protocol for the file transfer.

*namespace* (1-30 characters) identifies the namespace to use as a destination.

*vol* (1-1024 characters) is the volume where the file will go.

*dest-file-path* (optional, 1-1024 characters) is the destination path for the file, starting at the volume root. If you omit this, the file goes to the volume root and keeps its original name.

**format** {text|report|csv|xml} (optional) applies to the “reports” directory only. This chooses the output format for the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the reports in plain-text format.

**Default(s)** None

**Guidelines** The CLI chooses a user identity to establish its read/write privileges in the ARX volume. It chooses its identity based on the transfer protocol. For NFS, the CLI uses *root* as its identity. For CIFS, the CLI uses the [proxy-user \(gbl-ns\)](#) for the chosen namespace. These identities typically ensure that there are no permissions problems during the copy operation.

To copy a file to a volume instead of moving it, you can use the [copy {nfs|cifs}](#) command.

You can also move (or copy) files using several additional protocols. Use [move ... scp](#) or [copy scp](#) to use an SCP connection for the move or copy operation. The [move ... tftp](#) and [copy tftp](#) commands use TFTP (Trivial FTP) as a transport. To send out a file as an E-mail attachment, use [copy smtp](#). The [move ... ftp](#) and [copy ftp](#) commands use FTP to send files to an external server. To rename a file in its current ARX directory, you can use the [move](#) command.

The [move](#) commands only upload to an external server. The equivalent [copy](#) commands can also download. For example, the [copy {nfs|cifs}](#) command copies a file to or from an ARX volume.

To manage local files, use [delete](#) and/or [move](#). To view ASCII files, use [show directory file-name](#), [tail](#), and/or [grep](#).

**Guidelines: Wildcards** You can use several wildcard characters to select multiple file names:

- \* matches any string, including an empty string.
- ? matches any single character. This is also a special meta character in the CLI, so you must quote the file-path string to use it; for example, `move diag-info collNum?.tgz cifs medarcv /rcrds` would fail, but `move diag-info "collNum?.tgz" cifs medarcv /rcrds` would succeed.
- [] surrounds a class of characters (for example, [abcz]), and matches any one of the characters inside the square brackets (a, b, c, or z).
- [a-z] matches any single character from the range a through z (all lower-case).

**Sample** `bstnA# move cores core-* nfs wwmed /acct/.admin/`  
moves all core-dump files from the local “cores” directory to a hidden directory in “wwmed~/acct,” an NFS volume.

**Related Commands** [move](#)  
[move ... ftp](#)  
[move ... scp](#)  
[move ... tftp](#)  
[copy ftp](#)  
[copy scp](#)  
[copy tftp](#)  
[copy smtp](#)  
[copy {nfs|cifs}](#)  
[delete](#)  
[rename](#)  
[grep](#)  
[tail](#)  
[show directories](#)

---

## move ... scp

**Purpose** Use the `move ... scp` command to securely copy a file (such as a software-release file or a log file) to or from the ARX over SCP. This command deletes the file after it is successfully transferred, or leaves the file at the source location if the copy operation fails.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer  
(A backup-operator can move reports.)

**Syntax** `move directory file scp://[user@]server:dest-file`  
`[accept-host-key] [format {text|report|csv|xml}]`

*directory* is one of the following: **logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

*file* (1-1024 characters) identifies the file to move out of the above directory.

`scp://[user@]server:dest-file` (1-1024 characters) is the URL for the file's destination:

*user@* (optional if someone created an [ip scp-user](#)) is the username to present to the other end of the SCP connection. This user must be valid at the remote host. If you omit this and an [ip scp-user](#) is defined, it defaults to the username set by that command.

*server:* is the IP address or hostname for the SCP host. End with a colon (:).

*dest-file* is the desired path for the file at the remote host. Lead with a slash ("/") if the path is absolute (for example, "`scp://root@10.1.1.5:/var/arxDiags/6_5.tgz`").

Use no slash if the path is local to the home directory for *user* (for example, "`scp://root@10.1.1.5:6_5.tgz`").

**accept-host-key** (optional) means to accept an unknown SSH host key from the remote host, if it presents one.

**format {text|report|csv|xml}** (optional) applies to the "reports" directory only. This chooses the output format for the report. The "xml" option converts the report to XML format, "csv" converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the "text" and "report" options leave the reports in plain-text format.

**Default(s)** None

**Guidelines** If you enter a username in this command, the CLI prompts you for a password. Enter the password for the *user* in the URL. The file is transferred over SCP, which uses a secure, encrypted connection to the remote host.

Every host identifies itself with an encrypted SSH key. Whenever the ARX transfers a file using SCP, it exchanges keys with the remote host. If the remote-host key is different from one received previously, the host may not be the one you intended; an attacker may be posing as the intended host. For this reason, the ARX does not download or upload to a host with an unknown key unless you raise the **accept-host-key** flag. Note that the first contact with any server will require this flag to succeed.

The ARX deletes all SSH host keys on reboot, so all remote hosts are again unknown when the switch comes back up.

**Guidelines: Additional  
Commands for  
Moving and Copying  
Files**

To copy a file over SCP instead of moving it, you can use the [copy scp](#) command.

You can also move (or copy) files using several additional protocols. The [move ... tftp](#) and [copy tftp](#) commands use TFTP (Trivial FTP) as a transport. To send out a file as an E-mail attachment, use [copy smtp](#). The [move ... ftp](#) and [copy ftp](#) commands use FTP to send files to an external server. Use [move ... {nfs/cifs}](#) or [copy {nfs/cifs}](#) to move or copy a file to a volume on the current ARX. To rename a file in its current ARX directory, you can use the [move](#) command. The [move](#) commands only upload to an external server. The equivalent [copy](#) commands can also download. For example, the [copy scp](#) command copies a file to or from an external server.

To manage local files, use [delete](#) and/or [move](#). To view ASCII files, use [show](#) directory [file-name](#), [tail](#), and/or [grep](#).

**Sample**

```
bstnA# move capture ntap.cap scp://root@noc:/var/logs/arx2ntap.cap
accept-host-key
Password: root-password
```

uploads a packet-capture file to a host named “noc.” If the host key has changed for noc (or this is the first SCP to or from noc), the switch accepts the key and continues the upload.

(For details on creating a packet-capture file, see the documentation for the [capture session](#) command.)

**Related Commands**

[ip scp-user](#)  
[move](#)  
[move ... ftp](#)  
[move ... tftp](#)  
[move ... {nfs/cifs}](#)  
[copy scp](#)  
[copy ftp](#)  
[copy tftp](#)  
[copy smtp](#)  
[copy {nfs/cifs}](#)  
[delete](#)  
[grep](#)  
[tail](#)  
[show directories](#)

---

## move ... tftp

**Purpose** Use the `move ... tftp` command to transfer a file (such as a packet-capture file) off of the ARX via Trivial FTP (TFTP). This command deletes the file after it is successfully transferred, or leaves the file at the source location if the copy operation fails.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer  
(A backup-operator can upload reports to a remote host.)

**Syntax** `move directory file tftp://server/dest-file  
[format {text|report|csv|xml}]`

*directory* is one of the following: **logs**, **cores**, **configs**, **replicated-configs**, **reports**, **diag-info**, **software**, **scripts**, **capture**, or **license**.

*file* (1-1024 characters) identifies the source file from the above directory.

`tftp://server/dest-file` (1-1024 characters) is the URL for the destination file:

*server* is the IP address or hostname for the TFTP server.

*dest-file* is the new path for the file. Lead with an extra slash (“/”) if the path is absolute (for example, “tftp://10.1.1.5//var/diags/arxCllct.tgz”). Use only one slash if the path is local to the “tftpboot” directory. This conforms with the specification for FTP URLs in RFC 1738.

**format** {*text|report|csv|xml*} (optional) applies to the “reports” directory only. This chooses the output format for the report. The “xml” option converts the report to XML format, “csv” converts the report to a Comma-Separated-Value format (useful for spreadsheets), and the “text” and “report” options leave the report in plain-text format.

**Default(s)** None

**Guidelines** To copy a file over TFTP instead of moving it, you can use the [copy tftp](#) command. You can also move (or copy) files using several additional protocols. The [move ... scp](#) and [copy scp](#) commands use SCP (Secure CoPy) as a transport. To send out a file as an E-mail attachment, use [copy smtp](#). The [move ... ftp](#) and [copy ftp](#) commands use FTP to send files to an external server. Use [move ... {nfs|cifs}](#) or [copy {nfs|cifs}](#) to move or copy a file to a volume on the current ARX. To rename a file in its current ARX directory, you can use the [move](#) command. The [move](#) commands only upload to an external server. The equivalent [copy](#) commands can also download. For example, the [copy tftp](#) command copies a file to or from an external server. To manage local files, use [delete](#) and/or [move](#). To view ASCII files, use [show directory file-name](#), [tail](#), and/or [grep](#).

**Sample** `bstnA# move capture 11_12.cap tftp://tftp.f5.com/11_12_arx.cap`  
sends a packet-capture file, 11\_12.cap, to the TFTP server at tftp.f5.com.  
(For details on creating a packet-capture file, see the documentation for the [capture session](#) command.)

**Related Commands** [move](#)  
[move ... ftp](#)  
[move ... scp](#)  
[move ... {nfs/cifs}](#)  
[copy ftp](#)  
[copy tftp](#)  
[copy scp](#)  
[copy smtp](#)  
[copy {nfs/cifs}](#)  
[delete](#)  
[grep](#)  
[tail](#)  
[show directories](#)

---

## pause

**Purpose** This command is useful in writing/running scripts when you want to pause the CLI temporarily.

**Mode** (any)

**Security Role(s)** operator

**Syntax** `pause [seconds]`

*seconds* (optional; 0-3600) is the number of seconds to pause the CLI operation. If you omit this argument, the **<Enter>** key stops the pause.

**Default(s)** 0 (indefinite pause, until you press **<Enter>**)

**Guidelines** You can use this command with [terminal clear](#), which is also useful in writing scripts. For example, you could write a script that lets you view share status during a managed-volume import:

```
terminal clear
show share status
pause 60
terminal clear
show share status
pause 60
terminal clear
show share status
pause 60
terminal clear
show share status
pause 60
terminal clear
show share status
```

**Samples** `bstnA# pause 300`  
pauses the CLI for 300 seconds (five minutes).

```
bstnA# pause
Press <enter> to continue.
pauses the CLI until you press <Enter>.
```

**Related Commands** [run](#)  
[terminal clear](#)

## remark

|                         |                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use this command to enter a text-string comment into the syslog.                                                                                                                                                                                                                                                                                                       |
| <b>Mode</b>             | (any)                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Security Role(s)</b> | operator                                                                                                                                                                                                                                                                                                                                                               |
| <b>Syntax</b>           | <b>remark {critical   error   warning   notice   info   debug} <i>comment-string</i></b><br><br><b>critical   error   warning   notice   info   debug</b> is a required choice. This sets the severity of the message.<br><br><b><i>comment-string</i></b> (1-255 characters) is the message text. Insert quotation marks around the string if it contains any spaces. |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines</b>       | Use <a href="#">show logging levels</a> to verify the log-level settings for each component.<br>From any mode, use <code>show logs syslog</code> or <code>grep pattern logs syslog</code> to view the log messages in the syslog file. See the manual, <a href="#">ARX Log Catalog</a> , for a full list of log messages.                                              |
| <b>Sample</b>           | <code>bstnA# remark critical "J. Random bringing down NFS"</code><br>enters a critical message into the syslog.                                                                                                                                                                                                                                                        |
| <b>Related Commands</b> | <a href="#">show logging levels</a><br><a href="#">pause</a><br><a href="#">grep</a>                                                                                                                                                                                                                                                                                   |

## run

**Purpose** This command enables you to run a CLI script.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `run {scripts | configs} script-name`

`scripts` | `configs` selects the directory that holds the script. Use [show scripts](#) or [show configs](#) for file listings in these directories.

*script-name* (1-1024 characters) identifies the CLI script file to run. Use `show scripts` to display the scripts directory contents.

**Default(s)** None

**Guidelines** Use this command to run a CLI script. You can only run a script that is in the `scripts` or `configs` directory. The script is comprised of CLI commands, one per line. Comments start with a semi-colon (;).

To download a CLI-script file from an FTP, SCP, TFTP or other network service, use the `copy` command. If you want to run the script periodically, on a schedule, use the `at ... do run` command.

There are several CLI commands (such as [attach](#)) that do not get committed until you exit the mode with either `exit` or `end`. The best practice is to use the `end` command at the end of any script; you can use this command from any mode under `cfg` or `gbl` mode.

If you auto-generate a script (for example, with [show running-config](#) or [show global-config](#)), you must edit the script before you run it on an earlier release of ARX software. Command syntax may have changed as well as the best practices for command order. Consult the documentation from the earlier release (available from the GUI) and change the script's commands as needed before you use this command to run it.

**Sample** `bstnA# run scripts testdemo1.scr`  
runs the script, "testdemo.scr."

**Related Commands** [copy ftp](#)  
[copy scp](#)  
[copy tftp](#)  
[copy {nfs|cifs}](#)  
[show scripts](#)  
[show configs](#)  
[show software](#)  
[show directories](#)

| <b>Syntax</b>           | <code>show at</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines</b>       | <p>Use the <code>at</code> command to schedule a CLI job to run in the future.</p> <p>This command displays two rows per scheduled CLI job. Each pair of rows contains the following columns:</p> <p><b>Job</b> is a numeric ID for the scheduled job. This is assigned by the CLI when the user issues the <code>at</code> command. You can use this ID with <code>clear at</code> to clear the job.</p> <p><b>NextTime</b> is the date and time for the next scheduled job run. This is in the following format: <i>mm/dd/yyyy.HH:MM</i>.</p> <p><b>Interval</b> is the time between runs, if there is one. This is the <b>every interval</b> part of the <code>at</code> command.</p> <p><b>Command</b> is the exact CLI command (or script) that is invoked at each run.</p> <p><b>Report</b> is the prefix for the report generated at each run, if there is one. Each report is named as follows: <i>report-prefix_yyyymmddHHMM.rpt</i>. The part after the underscore is the date and time of the run. Use <code>show reports</code> to view the reports, if there are any.</p> |
| <b>Sample</b>           | <pre>bstnA# show at</pre> <p>shows all scheduled commands and scripts. See <a href="#">Figure 7.7</a> for sample output.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## show capture

|                         |                                                                                                                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The capture directory stores all files created by capturing IP traffic. Use this command to display the contents of the capture directory and/or the contents of a specified capture file. |
| <b>Mode</b>             | (any)                                                                                                                                                                                      |
| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                                                                                        |
| <b>Syntax</b>           | <b>show capture</b> [ <i>file-name</i> [summary [cifs non-cifs]]]                                                                                                                          |

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the CLI shows a list of all files in the directory.

**summary** (optional) reduces the output to a group of summary tables, like those shown with **Tshark -z**.

**cifs** | **non-cifs** (optional) is a filter on the summary output. If you choose **cifs**, the summary only counts packets related to CIFS traffic. These are packets to or from UDP/88, TCP/88, UDP/137, UDP/138, TCP/139, and/or TCP/445. The **non-cifs** option summarizes all packets *except* the ones to or from those ports.

- Guidelines** You can capture IP traffic into a file with the [capture session](#) command. This command shows a list of all captured files or shows the contents of one of them.
- The contents of the capture file are similar to the output of TShark, a commonly available network-packet analyzer. The TShark program is built on the same Packet Capture (PCap) library as WireShark, a similar program with a graphical interface.
- The capture summary is similar to the output of **Tshark -z**. This shows a table of UDP conversations and TCP conversations, followed by RTT statistics for NFSv2, NFSv3, and SMB (or CIFS). The TCP and UDP tables have one row per pairing of IP addresses. The NFS tables do not appear if you use the **cifs** option, and the SMB tables do not appear if you enter the **non-cifs** option.
- Use the [show directories](#) command to show the contents of all directories on the ARX. To maintain this directory, use the [copy](#), [move](#), [grep](#), and [delete](#) commands.
- While a capture session is underway, the ARX writes to its output file each time it captures IP packets. If the capture session writes to multiple files, it creates them all with a time stamp in each of their names. Use [show capture sessions](#) for a list of capture sessions that are currently underway.

**Samples** bstnA> show capture

```
capture
cifsVol.cap 06/29 01:55 220 kB
clientCap.cap 06/29 01:45 15 MB
fsrvr.cap 06/29 02:12 224 kB
nasTraffic.cap 06/29 01:55 212 kB
ntaps_00001_20110629060427.cap 06/29 02:04 24 B
proxyTraffic_01620_20110629055529.cap 06/29 01:55 150 kB
proxyTraffic_01621_20110629055531.cap 06/29 01:55 94 kB
```

lists the directory contents.

```
bstnA> show capture nasTraffic_00001_20060328081103.cap
```

Shows the contents of a capture file. See [Figure 7.8](#) for sample output.

```
bstnA> show capture nasTraffic.cap summary
```

Summarizes the contents of a capture file. See [Figure 7.9 on page 7-46](#) for sample output.

## show configs

**Purpose** Use this command to display the configs directory, which contains the switch's configuration files. You can also use this command to read one file from the directory.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show configs [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the CLI shows a list of the directory's files.

**Guidelines** Use the [show directories](#) command to show the contents of all directories on the ARX. To maintain this directory, use the [copy](#), [move](#), [grep](#), and [delete](#) commands.

The following files commonly appear in the configs directory:

- `acopia.keystore` is the SSH key for HTTPS connections to the GUI. This is the GUI's "security certificate" that is discussed in a pop-up when you first connect to the GUI. This file is in binary format, so you cannot read it. If you [delete](#) this file and restart the GUI (using [gui restart](#)), the ARX generates a new, self-signed, security certificate.
- `omDbVersion.info` contains the last understood database version. During a software upgrade, the ARX uses this file to determine if it requires a change in the database schema.
- `boot-config` contains the configuration parameters for setting up the administrative account created in the initial-boot script. This is a text file that can be run as a CLI script. The ARX runs this after it boots if (and only if) the `startup-config` is missing.
- `startup-config` is binary file with all configuration parameters on the ARX. The ARX uses this after it boots to recreate its entire configuration. It ignores the `boot-config` file if this file is present. You cannot view this file directly, though you can use [copy startup-config](#), [copy running-config](#), or [copy global-config](#) to copy the `startup-config` (or its components, the `running-config` and `global-config`) to a CLI script.

---

**Sample** bstnA# show configs

```
configs
 wmed.keystore 06/16 10:33 1.3 kB
 active.license 06/29 01:08 9.3 kB
 arx.dossier 04/11 22:54 3.0 kB
 arx.regkey 06/29 01:08 34 B
 boot-config 06/29 01:15 1.5 kB
 eeprom.dat 06/29 00:17 119 B
 fbstat.out 06/29 02:05 41 kB
 nlmd_ports.conf 06/29 00:19 52 B
 NSM_WR.cfg 06/23 13:53 10 kB
 oem-menu-log.txt 06/29 00:13 3.1 kB
 omDbVersion.info 06/29 00:16 281 B
 post_login.conf 06/29 01:14 40 B
 startup-config 06/29 02:05 7.5 MB
```

**Related Commands**

- [copy ftp](#)
- [copy scp](#)
- [copy tftp](#)
- [copy smtp](#)
- [copy {nfs/cifs}](#)
- [copy ron](#)
- [move](#)

- [move ... scp](#)
- [move ... tftp](#)
- [move ... {nfs/cifs}](#)
- [delete](#)
- [show directories](#)

## show cores

**Purpose** A *core file* contains system-memory dumps from a software failure; this information is very useful in diagnosing software problems. All core files reside in the `cores` directory. Use the `show cores` command to display this directory or information from a core file.

**Mode** (any)

**Security Role(s)** `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

**Syntax** `show cores`  
`show cores file-name { backtrace | syslog | list | message | cmdinfo }`

*file-name* (optional, 1-1024 characters) is the name of the core file to view.

`backtrace | syslog | list | message | cmdinfo` is a required choice.

**backtrace** displays information from the current program stack. See [Figure 7.10 on page 7-51](#) for a sample backtrace.

**syslog** displays contextual lines from the syslog file (many lines before and 20 lines after the core-dump event).

**list** shows what types of information/files you can extract from the core file. You can use one of these items with `show cores file-name list-item` syntax, described below.

**message** displays the syslog-file message that announced the core dump. Use the time stamp in this message to focus on the time of the software failure.

**cmdinfo** displays the CLI output for the specified file/argument.

**Guidelines** Use the `copy` command to copy the file off to an FTP server, an SCP host, a TFTP server, an E-mail recipient, or a namespace. The `move` command can send the file to one of those destinations and delete the original. Use `move` (with a local destination) to rename it, or `delete` to remove it.

**Samples** `stoweA# show cores`

```
cores
 core-0001.dmp 06/29 03:50 332 kB
 core-0002.dmp 06/29 03:51 335 kB
```

shows two core-dump files.

```
bstnA> show cores core-0012.dmp backtrace
```

shows the backtrace in another core-dump file. See [Figure 7.10](#).

## show diag-info

**Purpose** Use this command to display the contents of the diag-info directory.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show diag-info`

**Guidelines** If someone issues a `collect` command with a local file as the target, a large diagnostics file is written to the diag-info directory. Use this command to prove that the file was created. Use the `copy` command to copy the file off to an FTP server, an SCP host, a TFTP server, an E-mail recipient, or a namespace. The `move` command can send the file to one of those destinations and delete the original. Use `move` (with a local destination) to rename it, or `delete` to remove it.

To conserve disk space, the system only stores one diag-info file at a time.

**Sample** `bstnA> show diag-info`

```
diag-info
 juser-ns-wwmed.tgz 06/29 08:17 6.3M
```

**Related Commands** `collect`  
`copy ftp`  
`copy scp`  
`copy tftp`  
`copy smtp`  
`copy {nfs|cifs}`  
`move`  
`move ... ftp`  
`move ... scp`  
`move ... tftp`  
`move ... {nfs|cifs}`  
`delete`  
`show directories`

---

## show directories

**Purpose** The ARX contains directories on its hard disks where you can store release files, configuration scripts, and other switch-maintenance files. Use the `show directories` command to display all directories or enter `show directory-name` to display the contents for one directory only.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show directories`  
`show {releases | license | logs | stats-logs | cores | configs | reports | diag-info | auto-diagnostic | software | scripts }`

`directories` shows all directories and their contents

`releases | logs | ... | scripts` focuses on one directory.

**Guidelines** The `show directories` command displays the maintenance files on the ARX's local hard disks. To maintain these directories, use the `copy`, `move`, `grep`, and `delete` commands.

**Samples** `bstnA> show directories`  
 shows all directories and their contents. See the sample output in [Figure 7.11](#), below.

`bstnA> show releases`  
 shows the contents of the releases directory.

**Related Commands** `copy ftp`  
`copy scp`  
`copy tftp`  
`copy {nfs|cifs}`  
`copy smtp`  
`move`  
`move ... ftp`  
`move ... scp`  
`move ... tftp`  
`move ... {nfs|cifs}`  
`delete`  
`grep`

*Figure 7.11 Sample Output: show directories*

```
bstnA# show directories
```

```
releases
 test1.rel 06/24 10:23 1.0 GB V6.01.000.14033
R A test2.rel 06/29 00:18 1.0 GB V6.01.000.14032
B test3.rel 06/28 21:06 1.0 GB V6.01.000.14036
```

# show license

**Purpose** Use this command to display the contents of the license directory and/or the contents of a specified license file. A license file specifies the features and capacity that are licensed for use on this ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show license [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the command displays the list of the directory's files.

**Guidelines** Issue the command to view the directory contents. Then issue the command with a file name to view the contents of the given license file. The documentation for [show active-license](#) describes the detailed output for a license file.

If the directory listing does not include an "active.license" file, no license is active for the current ARX. You can use the [license activate](#) command to automatically activate a license, but only if the ARX is connected to the Internet. For an ARX that is off of the Internet, you can manually activate the license. Start with the [license create license-dossier](#) command for manual activation.

**Samples** `stkgbrgA# show license`  
shows all license files on the switch. For sample output, see [Figure 7.12 on page 7-58](#).

`stkgbrgA# show license active.license`  
shows the currently-active license file. For sample output, see [Figure 7.13 on page 7-58](#).

**Related Commands** [show active-license](#)  
[license activate](#)  
[license create license-dossier](#)

## show logs

**Purpose** Use this command to display the contents of the logs directory and/or the contents of a specified log file.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show logs [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the command displays the list of the directory's files.

**Guidelines** Issue the command to view the directory contents. Then issue the command with a file name to view the file contents.

The syslog file is arguably the most-important file in the logs directory. It shows detailed logs from most of the switch software. You can use the [logging level](#) command to change the volume of messages from each software subsystem.

Namespaces, volumes, and shares are denoted in the syslog by their internal, numeric IDs: use the [show id-mappings](#) command to translate these IDs into names used in the CLI.

**Sample** bstnA# `show logs`

```
logs
 error.log 06/29 02:03 185 kB
 fastpath 06/29 01:55 33 kB
 ha-reboot-history.log 06/29 00:13 322 B
 syslog 06/29 02:05 5.2 MB
 traplog 06/29 02:04 594 kB
```

**Related Commands** [copy ftp](#)  
[copy scp](#)  
[copy tftp](#)  
[copy {nfs|cifs}](#)  
[copy smtp](#)  
[move](#)  
[move ... ftp](#)  
[move ... scp](#)  
[move ... tftp](#)  
[move ... {nfs|cifs}](#)  
[delete](#)  
[show directories](#)

## show releases

**Purpose** A software release for the ARX is packaged in a *release file*. All release files are stored in the “releases” directory. Use this command to display the contents of the releases directory and/or the version of a specified release file.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show releases [file-name] [verbose]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the command displays the list of the directory’s files.

**verbose** (optional) runs a checksum test on the integrity of the downloaded release file.

**Guidelines** Issue the command without any options for a list of release files on the ARX. Then issue the command with a file name to view the specific release file.

The directory output shows one row for each release file. The table has five columns:

Flags appear in the first column to indicate how the release file is used:

- **B** is a flag for the Backup release, if any. This is the software release that was running prior to the current release. F5 personnel can roll the switch back to this release if needed.
- **R** is the flag for the currently-Running release.
- **A** flags the Armed release. This is the software to be loaded on the next reboot. Use `boot system` to arm the switch with a new release file. Use `reload` to reboot and put the new release file into service.

The release-file name is in the next column.

The date and time, in the third column, is the time the file was copied to the switch.

The size of the file is in the fourth column.

The next column, usually blank, says “incomplete” between the time that the file is downloaded and the switch has performed an integrity check. The switch does not use the release file until this check is complete. It should complete at the end of the download, automatically; a poorly-timed switch reload may prevent the check. In this case, replace the file.

The version of the release appears in the final column. The version appears in *Vrelease.build* format, where *build* is a specific build in the given *release*. For example, “V5.02.000.12574” would appear for build 12574 of release 5.02.000.

If you issue the command with a file name, the output shows the version number, the date the release was built, and the username that ran the build. If you use the **verbose** option, the results of a checksum test appear. If this shows that the checksum failed, retry the **copy** of the release file.

**Samples** provA# show releases

shows all releases on the switch. For sample output, see [Figure 7.14](#), below.

```
provA# show releases test1.rel
Version 5.02.000.12568 (May 14 2010 20:19:21) [nbuilds]
shows one release file.
```

```
provA# show releases test1.rel verbose
Version 5.02.000.12568 (May 14 2010 20:19:21) [nbuilds]
Checksum: Passed
shows that the release file's checksum passed.
```

**Related Commands**

B test2.rel 06/07 09:04 1.0 GB V5.02.000.12577
 test3.rel 06/27 03:05 1.0 GB V6.01.000.14030
```

## show replicated-configs

**Purpose** Use this command to display the replicated-configs directory, which contains configuration files from a remote ARX. You can use these files to recreate the remote configuration in case of a disaster at the remote site.

You can use this command to list all of the replicated-configuration files on the current ARX, or to read one configuration file from the directory.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show replicated-configs [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the CLI shows a list of the directory's files.

**Guidelines** Use the [show directories](#) command to show the contents of all directories on the ARX. To maintain this directory, use the [copy](#), [move](#), [grep](#), and [delete](#) commands.

This holds global-configuration files from remote ARX clusters. You can create a [config-replication](#) rule to regularly copy a global-config file from one cluster to another. The file's contents are an ordered list of CLI commands required to recreate the remote cluster's global configuration; they are the same as the output for [show global-config](#).

**Samples** `newptA# show replicated-configs`

```
configs-replication
 provSvcs.rcfg 04/02 03:08 12 kB
 testrun2.rcfg 04/02 03:08 12 kB
```

lists all replicated-config files on the "newptA" chassis.

`newptA# show replicated-configs provSvcs.rcfg`

shows the above file's contents. For sample output, see [Figure 7.15 on page 7-63](#).

---

**Related Commands**

## show reports

**Purpose** Use this command to display the contents of the reports directory and/or the contents of a specified file in the directory.

**Mode** (any)

**Security Role(s)** operator or backup operator (any)

**Syntax** **show reports**  
**show reports *report-name***  
**show reports type *report-type***  
**show reports type *report-type* *report-name***

If you omit both options, the command displays the full list of the directory's files.

*report-name* (optional, 1-1024 characters) is the name of the report to display.

*report-type* (optional, 1-12 characters) specifies the type of report to list. Enter **show reports type ?** for a full list of report types.

**Guidelines** Issue the command (perhaps with a **type** specification) to view the directory contents. Then issue the command with a file name to view the file contents.

When you use the command to list reports, the output is a table with one line per report. Each line shows a summary status for the job that generated the report. To see the one-line status for a particular report, use [show reports status](#).

Some reports run over a long period of time. To wait for a report to finish (perhaps in a CLI script), you can use [wait-for report](#).

**Samples** bstnA# **show reports**  
lists all reports. See [Figure 7.16 on page 7-65](#) for sample output.

bstnA> **show reports inconsistencies.12.rpt**  
shows one report. See [Figure 7.17 on page 7-68](#).

bstnA> **show reports type Imp**  
shows all import reports. See [Figure 7.18 on page 7-69](#).

[charts] 192.168.25.20:histories
[bulk] 192.168.25.27:bulkstorage

**** Legend:
**** LF = File exists in the metadata, but is missing from the physical filer.
**** LD = Directory exists in the metadata, but is missing from the physical filer.
**** FF = File exists on the physical filer, but is missing from the metadata.
**** FD = Directory exists on the physical filer, but is missing from the metadata.
**** LL = File is a symlink in the metadata, but is a regular file on the filer.
**** FL = File is a symlink on the filer, but is a regular file in the metadata.
**** IF = Filehandles in the metadata do not match the filehandles on the physical filer.
**** MF = The file is currently being migrated.
**** NL = Unable to lock parent directory during report.
**** FE = Error contacting filer during report.

```

```

**** FO = Filer Offline: The filer is offline or disabled.
**** F8 = A file name matches a CIFS alternate "8.3" name on another share.
**** D8 = A directory name matches a CIFS alternate "8.3" name; its contents will be skipped.
**** DC = A client has the file or directory open for delete-on-close, but the filer has already
deleted it.
**** SD = Striped leaf directory found on filer, expected on other shares.
**** SL = File is a symlink.
**** UT = Name contains characters that are invalid UTF-8; must solve issue directly on the filer
**** IS = Inconsistent attributes on one of this directory's stripes (discovered)
**** MI = Attributes are consistent, metadata marked as inconsistent
**** SI = Attributes are inconsistent, metadata not marked as inconsistent

## show reports status

**Purpose** Use this command to show a one-line summary of a given report.

**Mode** (any)

**Security Role(s)** operator (any except backup operator)

**Syntax** `show reports status report-name`

*report-name* (optional, 1-1024 characters) is the name of the report to summarize.

**Guidelines** Use this command to get a one-line status for the job that created the report. The line is the same as the one shown by [show reports](#). The line shows a summary status for the job that generated the report, with the following fields:

*report-name.rpt last-mod-time size type status*

*report-name* identifies the report. For time-sensitive reports, this name contains a date stamp for when the report was created, either manually or on a schedule. The report is created when an administrator invokes a report-generating command or when a rule's [schedule](#) fires.

*last-mod-time* is the time of the report's most-recent change.

*size* is the amount of internal-disk space that the report uses. You can use [copy ftp](#) and similar commands to copy reports off the ARX, and [delete reports \*report-name\*](#) to clear a report from the disk.

*type* indicates the process that created the report. This column uses the same abbreviations used for the [type report-type](#) option, above.

*status* shows the current or final state of the operation (typically DONE or FAILED) followed by a summary of the results. The summary shows a number of objects processed (such as files and directories) and the elapsed time for the report run. The elapsed time is the time since the report was created, which may be longer than the actual time the process ran; view the report contents to find actual processing times.

**Sample** `bstnA# show reports status status import.2.bills.6.rpt`  
shows the status for an import report. See [Figure 7.19](#) for sample output.

**Related Commands** [show reports](#)

## show scripts

**Purpose** Use this command to display the contents of the scripts directory and/or the contents of a specified script file.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show scripts [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the command displays the list of the directory's files.

**Guidelines** Issue the `show scripts` command to view the directory contents. Then issue the command with a file name to view the file contents.

**Samples** `bstnA# show scripts`

```

# show software

**Purpose** Use this command to display the contents of the ARX software directory and/or the contents of a specified MIB file in that directory.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show software [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the command displays the list of the directory's files.

**Guidelines** The software directory contains MIBs, user documentation, and some useful scripts. Issue the `show software` command to view the directory contents. Then issue the command with a file name to view the file contents (this only works with the text-based files, such as MIBs and scripts).

To view the documentation, use one of the `copy` commands ([copy ftp](#), [copy scp](#), [copy {nfs|cifs}](#), [copy tftp](#), or [copy smtp](#)) to upload it to an external machine. Then use a standard PDF reader or plugin. PDF readers are freely available on the Internet.

**Sample** `bstnA# show software`  
shows the full contents of the software directory. See [Figure 7.20](#) for sample output.

---

## show stats-logs

**Purpose** The ARX has an internal [stats-monitor](#) process that monitors communication with external devices (such as filers and clients) and places statistical data about this communication in the “stats-logs” directory. Use this command to display the contents of the stats-logs directory or the contents of a specific stats-log file.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show stats-logs [file-name]`

*file-name* (optional, 1-1024 characters) is the name of the file to display. If you omit this, the command displays the list of the directory’s files.

**Guidelines** Issue the command to view the directory contents. Then issue the command with a file name to view the file contents.

The stats-logs are all in CSV format, so that you can copy them onto an external device and use Microsoft Excel (or a similar spreadsheet application) to view them as spreadsheets. You can use [copy ftp](#), [copy {nfs|cifs}](#), [copy smtp](#), or similar copy commands to copy these files off of the ARX.

If you select a stats-monitor [sampling interval](#) that is shorter than the default, the stats-monitor process writes to these .csv files more frequently. These .csv files are kept (together with all other log files) on a separate disk partition from configuration files and other important data. Each hour, the stats-monitor creates an hourly file with the first line of the new hour; this is a summary of the data in the raw file. The stats-monitor files are not permitted to consume more than 80% of the log partition. If the .csv files approach their size limit, the oldest raw-data files are removed and the hourly-summary files remain.

**Guidelines: File Names** The stats-log files use the following naming convention:

`source_YYYYMMDD_hhmmss.{raw|hourly}.stats.csv`

where

- **source** is the source process or group of devices that generated the statistics. These are
  - “cifs-service” (related to a [cifs](#) front-end service and its clients; these statistics are similar to the CIFS output from [show statistics namespace ... summary](#)),
  - “cifs-service-auth” (CIFS-authentication statistics, also visible with [show statistics cifs authentication](#)),
  - “nfs-service” (for an [nfs](#) service and its clients, similar to the NFS output from [show statistics namespace ... summary](#)),
  - “cifs-share” or “nfs-share” (back-end [shares](#) behind an ARX [volume](#), viewable with [show statistics namespace ... summary](#) on an individual share),
  - “metadata” (used to locate files behind a managed volume, and stored on an external [metadata share](#); you can also see these statistics with [show statistics metadata](#)),

**Guidelines: File Names (Cont.)**

- “metalog” (volume-state information required for [redundancy](#) failovers; these statistics are also viewable with [show statistics metalog](#)),
  - “cifs-work-queue” (internal data structures for managing CIFS tasks, also viewable with [show statistics cifs work-queues](#)),
  - “domain-controller” (related to traffic between internal CIFS processes and external DCs; these statistics are similar to the output from [show statistics domain-controller](#)), and
  - “migration” (related to [place-rules](#) and other policies that migrate files between back-end shares; these statistics are related to the output from [show statistics migration](#)).
- **YYYYMMDD\_hhmmss** is the date and time the file was created.
  - **raw|hourly** differentiates between a file with raw data and an hourly file with roll-up data. The stats-monitor process writes to each raw-data file as often as dictated by the [sampling interval](#) setting. It creates an hourly file for each source once per hour, with the first set of data for the next hour. If the sampling interval is less than one hour, the hourly files act as summaries of the raw-data files: they show the data samples at the beginning of the hour, but not the changes in those values during the hour.

**Guidelines: File Format**

The top line of any stats-log file has the following format:

```
BEGIN source version=v timestamp=nnnnnnnnnn
```

where

- *source* is the same as the source in the file name, defined above,
- *v* is a version number for the stats-monitor, and
- *nnnnnnnnnn* is the number of seconds since the first second of 1970, UTC.

The second line shows the data types of each field in the file’s rows. The possible data types are

- **TIMESTAMP** identifies a time as the number of seconds since epoch, as above.
- **KEY** is a unique value that identifies the object being monitored (such as a volume-group ID).
- **COUNTER** is an integer to show a count.
- **INTERVAL** and
- **TOTALTIME** are time intervals, in microseconds (millionths of a second).
- **TEXT**

The third row is the name of each field.

The remaining rows contain data, arranged in columns below the names in the above row.

STATS\_RESET marks when a reboot, a [clear statistics cifs work-queues](#), or a [clear statistics filer](#) occurred to clear some statistics. This has a “ts” (time-stamp) field, followed by some KEY fields to identify the object statistics that were cleared.

**Samples** bstnA# show stats-logs

shows a list of all stats-log CSV files. See [Figure 7.21](#) for sample output.

```
provA# show stats-logs metadata_20110705_041347.raw.stats.csv
```

shows a particular stats-log CSV file. See [Figure 7.22 on page 7-78](#) for sample output.

---

# tail

**Purpose** Use the tail command to display the end of a file selected from a specified directory.

**Mode** (any)

**Security Role(s)** network-technician

**Syntax** `tail {releases | logs | stats-logs | cores | configs | replicated-configs | reports | software | scripts | capture | license} file-name [lines | follow]`  
`tail capture file-name [lines]`

`releases | ... | license` identifies the directory. This is a required choice.

`file-name` (1-1024 characters) identifies the file to display.

This command shows the last 24 lines of the file. You can use the optional *lines* argument or **follow** flag to change the number of lines:

*lines* (optional; 1-4096) is the number of lines at the end of the file to display.

**follow** (optional) makes the CLI follow the file as it grows.

**Guidelines** Use [show directories](#) to view a list of all files in all directories. Use `show directory-name` (for example, `show logs` or `show capture`) to list the files in one directory.

**Samples** `bstnA# tail logs syslog follow`  
tails the syslog file as it grows. This displays all syslog messages in real time.

`bstnA# tail logs syslog 100`  
displays the last 100 lines of the syslog file.

`bstnA# tail scripts myscript.scr`  
displays the last 24 lines of the “myscript.scr” script file.

`bstnA# tail capture cifsVol.cap follow`  
tails a packet-capture file, “cifsVol.cap,” as it grows. You can use the [capture session](#) command to start capturing packets and sending them to a file.

**Related Commands** [grep](#)  
[pause](#)  
[show directories](#)  
[show releases](#), [show logs](#), [show stats-logs](#), [show cores](#), [show configs](#),  
[show replicated-configs](#), [show reports](#), [show software](#), [show scripts](#), [show capture](#), [show license](#)

## truncate-report

**Purpose** To stop a process from generating a report, use the `truncate-report` command. This truncates the report without otherwise affecting the process.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `truncate-report file-name`

*file-name* (1-255 characters) identifies the report file to truncate. This must be a file in the “reports” directory; use [show reports](#) for a file listing.

**Guidelines** This command prompts for confirmation before truncating the report; enter `yes` to continue.

The `nsck` utility can generate several report types, one per `nsck` job. To stop the `nsck` utility from writing to the report, use this command. The utility continues processing after the report is truncated.

This command is used the same way for any report, from any process.

**Samples**

```
bstnA# truncate-report last-modified.22.rpt
Truncate report 'last-modified.22.rpt'? [yes/no] yes
bstnA#
 truncates a report.
```

**Related Commands** [show reports](#)

---

# wait-for report

**Purpose** Use the `wait-for report` command to wait until the ARX finishes writing a report.

**Mode** (any)

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `wait-for report report-name [timeout timeout]`

*report-name* (1-255 characters) identifies the report. You can use the [show reports](#) command to list all of them.

*timeout* (optional, 1-2096) is a timeout value, in seconds. This sets a time limit; if the report takes longer than this to complete, the `wait-for` operation quits.

**Default(s)** *timeout* - 0 (zero, meaning that the `wait-for` command should wait indefinitely)

**Guidelines** This command is useful in CLI scripts.

Many commands create reports to show their progress (such as [nsck ... report metadata-only](#)), and some internal operations generate reports (such as the various reports produced as a by-product of a share [enable \(gbl-ns-vol-shr\)](#)). You can use this command to wait for any given process to finish writing a report.

If you set a *timeout* and it expires before the report is finished, the command exits with a warning.

**Sample** `bstnA# wait-for report remService_medco_201005260714.rpt`  
waits for the ARX to finish writing a remove-service report.

**Related Commands** [show reports](#)

# 8

---

---

## Master Key

---

---

The *master key* encrypts and decrypts all of the Critical-Security Parameters (CSPs), such as passwords, on the ARX. You can use the master key in conjunction with the [show running-config](#) and [show global-config](#) commands to backup and restore the full switch configuration, including passwords.

---

## show master-key

**Purpose** The ARX supports a single *master key* that encrypts and decrypts all of its CSPs (such as passwords). You generate the master key as part of the switch's initial boot process; use the `show master-key` command to get an encrypted copy of the master key.

**Mode** (any)

**Security Role(s)** crypto-officer

**Syntax** `show master-key`

**Guidelines** This command prompts you for two passwords:

- **System Password** is a password entered at initial-boot time. It is 12-32 characters long. This validates that you have permission to access the master key.
- **Wrapping Password** is set with this command. The security software uses this to encrypt (and later decrypt) the master-key string.

Enter 12-32 characters. At least one character in this password must be a number (0-9) or a symbol (!, @, #, \$, and so on).

Save this password: you will need it to decrypt the master key later, on the secondary switch.

This command outputs a base64-encoded string that is the encrypted master key. Save this string *and* the wrapping password that you set in the command.

You can use these pieces of information to duplicate the master key later on a redundant switch; both switches in a redundant pair must share the same master key. If you set up two redundant pairs in a disaster-recovery configuration, where one pair is an active cluster (see [cluster-name](#)) and the other is a backup cluster, all four switches must share the same master key.

For maximum security, the encrypted master key and its wrapping password *must be saved separately*.

**Guidelines: Resetting the Master Key**

There are occasions where you may need to reset your master key. For example, your chassis may be designated for use in a backup cluster for a disaster-recovery setup, and may need the same master key as the switches in the active cluster. If the master key was not copied during installation, you must reset the switch to its factory defaults to change it.

You must clear your entire configuration to reset your master key. You can restore the running-config (network parameters), but the global-config (storage parameters) should remain clear for a backup switch. Follow these steps to reset a switch back to its factory defaults and reset its master key:

- Use the `copy running-config` command to copy the entire running configuration (network-level parameters, not storage parameters) into a file on the chassis.
- The ARX should not be running any storage services if it is designated as a backup; a backup is designed to take over services from the active switch or cluster after a failover. Use the `remove service` command to clear each service that is currently running, if any. This cleanly de-couples the ARX software from all back-end filers.
- Connect a serial cable to the Console port. Only the Console port is available after you take the next step.
- Use `delete startup-config` and `delete` configs `boot-config` to delete the entire configuration, and then run the `reload` command. This resets the machine to its factory defaults, disables all management-IP interfaces, and reruns the initial-boot script at the Console port.
- Use the initial-boot script to reset the master key. For detailed instructions on the initial-boot process, refer to the hardware-installation guide for your chassis.
- Invoke the `run` command on the running-config file that you saved onto the chassis earlier. This re-establishes all of your network parameters.

**Sample**

```
bstnA(cfg)# show master-key
System Password: Sup3r$ecretpw
Wrapping Password: An0ther$ecretpw
Validate Wrapping Password: An0ther$ecretpw
```

Encrypted master key:

```
2oftVCwAAAAGAAApwazSRFd2ww/H1pi7R7JMDZ9SoIg4WGA/XsZP+HcXjsIAAAADDRbMC
xE/bc=
bstnA(cfg)#
```

## blocked-vlan (cfg-vlan)

|                         |                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use this command to block an interface (a VLAN member) or a range of interfaces from receiving ingress traffic from the current VLAN. (Contrast this with <a href="#">no members (cfg-vlan)</a> , which removes the interface from the VLAN altogether.)                                                                                                    |
| <b>Mode</b>             | cfg-vlan                                                                                                                                                                                                                                                                                                                                                    |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>           | <b>blocked-vlan <i>slot/port</i> [to <i>slot/port</i> ]</b><br><b>no blocked-vlan <i>slot/port</i> [to <i>slot/port</i> ]</b><br><br><i>slot/port</i> (2/1-14 on ARX-4000; 1/1-4 or 2/1-2 on ARX-2500; 1/1-12 on ARX-2000; 1/1-8 on ARX-1500) is the first (or only) Ethernet port.<br><i>to slot/port</i> (optional) is the last port in a range of ports. |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                        |
| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                                                                                                                                                                                                       |
| <b>Guidelines</b>       | This blocks the interface from accepting incoming packets, but keeps using the interface for outbound packets. This only applies to packets from the current VLAN.<br>Use the <a href="#">show interface summary</a> command to locate all Ethernet ports on the chassis.                                                                                   |
| <b>Samples</b>          | <pre>bstnA(cfg-vlan[1])# blocked-vlan 2/5 to 2/6</pre> blocks ports 2/5 - 2/6 from VLAN 1.<br><br><pre>bstnA(cfg-vlan[7])# no blocked-vlan 2/3</pre> removes port 2/3 from being blocked on VLAN 7.                                                                                                                                                         |
| <b>Related Commands</b> | <a href="#">show interface</a><br><a href="#">show vlan</a>                                                                                                                                                                                                                                                                                                 |

## channel

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | <p>A <i>channel</i> is an aggregated group of Ethernet ports that function as one link, as defined in IEEE 802.3ad. You can configure up to eight channels on the ARX. From <code>cfg</code> mode, use the <code>channel</code> command to begin configuring a channel.</p> <p>Use <code>no channel</code> to remove the channel number configuration and return all member ports to their independent roles.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Guidelines</b>       | <p>We recommend disconnecting the ARX from the peer station before configuring the channel on either side. Once the channel is configured on both switches, connect the cables between them.</p> <p>This command puts you into <code>cfg-channel</code> mode, where you use <a href="#">members (cfg-channel)</a> to configure the channel's member ports and <code>no shutdown (cfg-channel)</code> to start traffic on the channel. For a channel that connects a redundant pair, configure the channel's member ports with <a href="#">redundancy protocol (cfg-channel)</a>. You can optionally use the <a href="#">description (cfg-channel)</a> command to set an optional name for the channel. The <a href="#">vlan (cfg-channel)</a> command assigns the channel to a VLAN, untagged. The <a href="#">vlan-tag</a> command assigns the channel to a VLAN in tagged mode; you can assign the channel to multiple VLANs by invoking this command once for each VLAN.</p> <p>By default, outbound traffic is load-balanced by hashing both the source and destination IP of an outbound packet. On some platforms you have the option to change the IP addresses used in this hash with the <a href="#">load-balance</a> command.</p> <p>Use the <a href="#">show channel</a> command to view the channel's configuration.</p> <p>All ports in a channel must be in the same VLAN(s). The station on the other side of the channel must have the same member ports and VLANs as the ARX; traffic cannot flow through the channel unless the channel configurations match. Additionally, the ports cannot have an "auto" speed.</p> <p>If spanning tree is running, the channel's VLAN determines its spanning-tree membership.</p> |

---

**Guidelines: Shutting Down the Redundant-Pair Link** If you use the `no channel` command on the channel that carries the redundant-pair link (see [redundancy protocol \(cfg-channel\)](#)) while redundancy is enabled ([enable \(cfg-redundancy\)](#)), the command causes the standby peer to reboot. The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the [redundancy protocol](#) or [redundancy protocol \(cfg-channel\)](#) command on another port or channel to establish a new redundant-pair link.

The CLI prompts for confirmation before removing the channel and shutting down the redundant-pair link; enter `yes` to proceed with the channel removal and the reboot.

**Sample**

```
bstnA(cfg)# channel 1
bstnA(cfg-channel[1])#
creates channel 1.
```

## clear counters lacp

**Purpose** Link-Aggregation Control Protocol (LACP) is a control protocol for dynamically managing the member ports in a channel. The peers on both ends of the channel use LACP to exchange information about member ports; the peers can automatically remove or replace member links if configuration changes disqualify/re-qualify them for channel membership.

For LACP statistics, use the `show channel ... lacp stats` command (see the documentation for [show channel ... stats](#)). Use this command to clear the current LACP statistics for all channels (or for a specified channel) and restart the count.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `clear counters lacp [channel id]`

*id* (1-8) identifies a single channel to clear. If you omit this option, the command clears the statistics for all channels. Use the [show channel summary](#) command to enumerate all configured channels.

**Default(s)** None

**Valid Platforms** ARX-1500 and ARX-2500 only

**Guidelines** The [channel](#) command creates a channel, and the [lacp active](#) or [lacp passive](#) command enables LACP on the channel. Use this command to clear and restart the statistics counters for LACP. Use [show channel ... stats](#) to view a channel's statistics (including LACP statistics).

The CLI prompts for confirmation before clearing the LACP counters; enter **yes** to proceed.

**Sample**  
stoweA# `clear counters lacp channel 2`  
Clear the LACP counters for channel 2? [yes/no] **yes**  
clears the current statistics count for channel 2.

**Related Commands** [show channel ... stats](#)  
[lacp active](#)  
[lacp passive](#)  
[channel](#)

## clear counters redundancy network

|                         |                                                                                                                                                                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use this command to clear the link-transition counters in the <code>show redundancy network</code> output.                                                                                                                                                                                               |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                                                                                |
| <b>Security Role(s)</b> | network-technician, network-engineer, storage-engineer, or crypto-officer                                                                                                                                                                                                                                |
| <b>Syntax</b>           | <code>clear counters redundancy network</code>                                                                                                                                                                                                                                                           |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                     |
| <b>Valid Platforms</b>  | any <i>except</i> ARX-VE                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>       | The link-transition counter increments every time the link status changes for a redundancy-protocol port (the link goes up or down). A redundancy-protocol port is used as one end of a redundant-pair link. Use the <a href="#">show redundancy network</a> command to see the link-transition counter. |
| <b>Sample</b>           | <pre>bstnA# clear counters redundancy network bstnA# clears the link-transition counters.</pre>                                                                                                                                                                                                          |
| <b>Related Commands</b> | <a href="#">show redundancy network</a><br><a href="#">clear counters redundancy</a>                                                                                                                                                                                                                     |

## description (cfg-if-gig)

**Purpose** A port can optionally have a description for its show commands. Use the `description` command to create a description for the current port.  
Use `no description` to remove the description.

**Mode** `cfg-if-gig`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `description description`  
`no description`

*description* (1-60 characters) is the description you choose for the current port. Quote the description if it contains spaces.

**Default(s)** No description

**Guidelines** The description appears in the output from the [show interface gigabit](#) command.

**Samples** `bstnA(cfg-if-gig[2/4])# description "link to back-end filers"`  
sets a description for the current port, 2/4.

`bstnA(cfg-if-gig[2/8])# no description`  
erases the description for port 2/8.

**Related Commands** [interface gigabit](#)  
[show interface gigabit](#)

# forward-delay

|                         |                                                                                                                                                                                                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The <i>Forward Delay</i> is the time for spanning-tree ports to stay in the listen and learn states, waiting for the best BPDU frame to reach the ARX. Use the <code>forward-delay</code> command to set the Forward-Delay time.<br><br>Use the <code>no</code> form to revert to the default Forward Delay. |
| <b>Mode</b>             | cfg-stp                                                                                                                                                                                                                                                                                                      |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                           |
| <b>Syntax</b>           | <code>forward-delay <i>seconds</i></code><br><code>no forward-delay</code><br><br><i>seconds</i> is a number from 4 to 30.                                                                                                                                                                                   |
| <b>Default(s)</b>       | 15 (seconds)                                                                                                                                                                                                                                                                                                 |
| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                                                                                                                                                        |
| <b>Guidelines</b>       | The Spanning-Tree protocol is defined in IEEE 802.1D.<br><br>The Forward Delay time should be at least twice the maximum transit time for a BPDU to traverse the entire network. This allows the bridges enough time to establish a new spanning-tree topology in case of a bridge or link failure.          |
| <b>Sample</b>           | <code>bstnA(cfg-stp)# forward-delay 10</code><br>sets the Forward Delay to 10 (seconds).                                                                                                                                                                                                                     |
| <b>Related Commands</b> | <a href="#">spanning-tree</a>                                                                                                                                                                                                                                                                                |

## flowcontrol

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | A high-speed (1000-tx-full or ten-gigabit) interface can transmit a flow-control request and/or accept and enforce a flow-control request for an over-burdened peer. Use the <code>flowcontrol</code> command to enable flow control.<br><br>Use the <code>no</code> form to disable flow control.                                                                                                                                                                                  |
| <b>Mode</b>             | <code>cfg-if-gig</code><br><code>cfg-if-ten-gig</code>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Syntax</b>           | <code>flowcontrol send {on   off}</code><br><code>flowcontrol receive {on   off}</code><br><code>no flowcontrol</code><br><br><code>on   off</code> is a required choice.                                                                                                                                                                                                                                                                                                           |
| <b>Default(s)</b>       | Disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Valid Platforms</b>  | In <code>cfg-if-gig</code> mode: ARX-1500, ARX-2000, ARX-2500, and ARX-4000<br>In <code>cfg-if-ten-gig</code> mode: ARX-2500 and ARX-4000 only                                                                                                                                                                                                                                                                                                                                      |
| <b>Guidelines</b>       | On a one-gigabit interface, the speed setting must be 1000-tx-full to enable flow control. Use the <a href="#">speed (cfg-if-gig)</a> command to set the speed on a single-gigabit interface. The <a href="#">show interface gigabit</a> and <a href="#">show interface ten-gigabit</a> commands show the current flow-control setting on a particular one-gigabit or ten-gigabit interface, respectively.<br><br>This command is not supported on the ARX-500 or ARX-VE platforms. |
| <b>Sample</b>           | <code>bstnA(cfg-if-gig[2/4])# flowcontrol send on</code><br>sets the interface to transmit flow-control requests. This does not necessarily accept any flow-control requests from peers.                                                                                                                                                                                                                                                                                            |
| <b>Related Commands</b> | <a href="#">interface gigabit</a><br><a href="#">speed (cfg-if-gig)</a><br><a href="#">show interface gigabit</a><br><a href="#">show interface ten-gigabit</a>                                                                                                                                                                                                                                                                                                                     |

# hello-time

|                         |                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The <i>Hello Time</i> is the interval (in seconds) between broadcasts of Bridge Protocol Data Units (BPDUs) to neighboring bridges. The BPDUs have spanning-tree topology information that a bridge uses to determine its role in the spanning tree. Use the <code>hello-time</code> command to set the Hello Time.<br><br>Use the <code>no</code> form to revert to the default Hello Time. |

| <b>Syntax</b>                                            | <code>interface gigabit slot/port</code><br><br><i>slot/port</i> (2/1-14 on ARX-4000; 1/1-4 on ARX-2500; 1/1-12 on ARX-2000; 1/1-8 on ARX-1500; 1/2 on ARX-500; 1/1 on ARX-VE) is a Gigabit Ethernet port. Use the <code>show interface summary</code> command to show all Gigabit Ethernet ports and their slot(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default(s)</b>                                        | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines</b>                                        | <p>This command puts you into <code>cfg-if-gig</code> mode, where you can set several configuration parameters for the port. Use the <code>speed (cfg-if-gig)</code> command to manually set the port speed and duplex configuration. If the device at the other end of the connection supports flow control, you can use the <code>flowcontrol</code> command to configure it. Use the <code>description (cfg-if-gig)</code> command to set an optional description for the port, for show commands. Use the <code>no shutdown (cfg-if-gig)</code> command to start the port.</p> <p>For every platform except the ARX-1500, ARX-2500, and ARX-VE, traffic-storm control is configured automatically at every gigabit interface. The ARX forwards a maximum of 1000 packets per second for each of the following frame types: broadcast, multicast, or unicast frames with unknown destination addresses. If the ingress-side of the port reaches the maximum in a given second, the port drops packets of the chosen type until the second is over. Traffic-storm control does not suppress spanning-tree BPDU packets. The ARX-1500, ARX-2500, and ARX-VE do not support traffic-storm control.</p> |
| <b>Guidelines: Port 1/1 on the ARX-1500 and ARX-2500</b> | <p>By default, port 1/1 on an ARX-1500 or ARX-2500 is configured as an out-of-band (OOB) management interface. You can use the <code>interface mgmt</code> command and its sub commands to manage this interface. The CLI returns an error message if you enter <code>interface gigabit 1/1</code> while port 1/1 is being used for out-of-band management.</p> <p>To re-assign this port to client/server traffic, use <code>no interface mgmt</code> to delete the out-of-band management interface. Then use this command on port 1/1 (<code>interface gigabit 1/1</code>) to enter <code>cfg-if-gig</code> mode and edit the port for client/server traffic.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Purpose</b>          | The ARX-4000 supports two ten-gigabit ports, which are called <i>interfaces</i> in the CLI. Use the <code>interface ten-gigabit</code> command to begin configuring a ten-gigabit interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Guidelines</b>       | <p>This command puts you into <code>cfg-if-ten-gig</code> mode, where you can set several configuration parameters for the port. The speed is fixed at 10 gigabits/second, full duplex. Use the <a href="#">description (cfg-if-ten-gig)</a> command to set an optional description for the port, for show commands. If the device at the other end of the connection supports flow control, you can use the <a href="#">flowcontrol</a> command to configure it. Use the <a href="#">no shutdown (cfg-if-ten-gig)</a> command to start the port.</p> <p>For every platform except the ARX-1500, ARX-2500, and ARX-VE, traffic-storm control is configured automatically at every ten-gigabit interface. The ARX forwards a maximum of 1000 packets per second for each of the following frame types: broadcast, multicast, or unicast frames with unknown destination addresses. If the ingress-side of the port reaches the maximum in a given second, the port drops packets of the chosen type until the second is over. Traffic-storm control does not suppress spanning-tree BPDU packets. The ARX-1500, ARX-2500, and ARX-VE do not support traffic-storm control.</p> |
| <b>Sample</b>           | <pre>bstnA(cfg)# interface ten-gigabit 2/1 bstnA(cfg-if-ten-gig[2/1])#     edits the ten-gigabit interface at slot 2, port 1.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## ip private vlan

**Purpose** Two private VLANs are used for inter-process communication in the ARX: the private VLAN and the metalog VLAN. The private VLAN carries a private IP network, used for inter-process communication. The metalog VLAN carries important namespace-software records to a battery-backed NVRAM device. These VLANs are configured during the initial boot process; it is rarely necessary to change them. Use the `ip private vlan` command to change one of these VLANs, or the IP subnet carried by the private VLAN.

**Mode** cfg

**Security Role(s)** network-engineer or crypto-officer

**Syntax** `ip private vlan internal vlan-id [metalog meta-vlan-id] [subnet ip-subnet mask]`

*vlan-id* (1-4095) is the number for the private VLAN.

**metalog *meta-vlan-id*** (optional; 1-4095) sets the number for the metalog VLAN. This *must* be different from the private VLAN, above.

**subnet *ip-subnet mask*** (optional) is the IP address and mask for the private subnet (for example, 169.254.14.0). The mask must be 24 bits (255.255.255.0) or less for an ARX-2000 or ARX-4000; it must be 26 bits (255.255.255.192) or less for an ARX-500. 255.255.255.0 defines a large enough subnet for any platform.

**Valid Platforms** ARX-500, ARX-2000, and ARX-4000

**Guidelines** The private and metalog VLANs must not be supported on any external LAN segments. If either VLAN is in use, use this command to change it/them.

You cannot change the private VLAN or subnet in a redundant pair (see [redundancy](#)).

You may need to change the *ip-subnet* in a large RON where two switches have the same private subnet. This is a rare situation, but possible. If it occurs, the current switch can only reach one of the conflicting switches over the RON: the switch that was connected to the current switch first. To reach the other switch, you must make their private subnets unique within the RON. The [show ron conflicts](#) command indicates which switches have the conflict, and shows all of the private subnets that are currently in the RON (and should therefore be avoided). The [ip private subnet reassign](#) command is designed to fix this by automatically choosing a unique private subnet; alternatively, you can set the subnet manually with this command. Go to the CLI for one of the conflicting switches and use either command to change its private subnet.

---

**Samples**    `bstnA(cfg)# ip private vlan internal 2222`  
Change the private VLAN and reboot the chassis? [yes/no] **yes**  
...  
          changes the private VLAN to 2222.

`bstnA(cfg)# ip private vlan internal 2222 subnet 169.254.166.0  
255.255.255.0`  
          changes the private VLAN to 2222, leaves the metalog VLAN as is, and changes  
the private subnet to 169.254.166.0/24.

`bstnA(cfg)# ip private vlan internal 2222 metalog 2223`  
          changes the private VLAN to 2222 and the metalog VLAN to 2223.

`prt1ndA(cfg)# ip private vlan internal 1002 subnet 169.254.200.0  
255.255.255.192`  
          changes the private subnet only, perhaps because of a conflict with another switch  
in the RON.

| <b>Purpose</b>          | Link-Aggregation Control Protocol (LACP) is a control protocol for dynamically managing the member ports in a channel. The peers on both ends of the channel use LACP to exchange information about member ports; the peers can automatically remove or replace member links if configuration changes disqualify/re-qualify them for channel membership. Use the <b>lACP active</b> command to enable LACP on the current channel, with the ARX as the active peer.<br><br>Use <b>no lACP</b> to stop sending LACPDU to the device at the other end of the channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Mode</b>             | cfg-channel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Guidelines</b>       | <p>LACP is defined in IEEE 802.1AX-2008. If you configure LACP for the channel, the peers can exchange Link Aggregation Control Protocol Data Units (LACPDUs) over each member port. The peers can use the state information in these LACPDUs to dynamically react to configuration or topology changes. For example, if a configuration change disqualifies one of the channel's member ports for aggregation, the ARX and its peer can use LACP to automatically remove the port's link from the channel. If another configuration change makes the link suitable for aggregation again, the LACP processes can automatically restore it to the channel.</p> <p>To establish LACP on the channel, enable passive LACP at the peer and use this command on the ARX. If you connect two ARX peers over a channel (see <a href="#">redundancy protocol (cfg-channel)</a>), you can use this command on both ARX peers to establish LACP; one of them assumes the passive LACP role automatically.</p> <p>To support LACP on chassis types other than the ARX-1500 or ARX-2500, you can use the <a href="#">lACP passive</a> command.</p> <p>If LACP is disabled, all member ports remain in the channel no matter what configuration or topology changes occur later.</p> |

### Important

*The **no lACP active** command restarts all of the channel's member ports. This stops all traffic on the channel for a brief time. This is not recommended for a busy channel; perform this operation only during off hours, or on an inactive channel.*

*For a channel used in a redundant-pair link (see the documentation for [redundancy protocol \(cfg-channel\)](#)), this causes the backup ARX to reboot. In most cases, the reboot has no effect on client traffic.*

**Guidelines (Cont.)** Use the [channel](#) command to create a channel, and use the [members \(cfg-channel\)](#) command to add a port to the channel. Each end of the channel should have the same LACP timeout settings; you can use the [lACP rate](#) command to change this end of the channel to a long timeout. The [show channel ... lACP](#) command shows the current configuration and status of LACP on a given channel. For LACP statistics, use the [show channel ... lACP stats](#) command (see the documentation for [show channel ... stats](#)).

**Samples**

```
stoweA(cfg)# channel 6
stoweA(cfg-channel[6])# no lACP active
```

Warning: Disabling LACP will result in temporarily loss of network connectivity for all members of this channel.

Are you sure? [yes/no] **yes**  
stops LACP processing on channel 6.

```
stoweA(cfg)# channel 1
stoweA(cfg-channel[1])# lACP active
starts LACP processing on channel 1.
```

| <b>Purpose</b>          | Link-Aggregation Control Protocol (LACP) is a control protocol for dynamically managing the member ports in a channel. The peers on both ends of the channel use LACP to exchange information about member ports; the peers can automatically remove or replace member links if configuration changes disqualify/re-qualify them for channel membership. Use the <code>lACP passive</code> command to enable LACP on the current channel.<br><br>Use <code>no lACP passive</code> to ignore all LACPDU s from the device at the other end of the channel. |
| <b>Mode</b>             | cfg-channel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>           | <code>lACP passive</code><br><code>no lACP passive</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default(s)</b>       | <code>no lACP passive</code> - static LACP (that is, no LACP) runs by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Valid Platforms</b>  | ARX-2000 or ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Guidelines** LACP is defined in IEEE 802.1AX-2008. If you configure LACP for the channel, the peers can exchange Link Aggregation Control Protocol Data Units (LACPDU s) over each member port. The peers can use the state information in these LACPDU s to dynamically react to configuration or topology changes. For example, if a configuration change disqualifies one of the channel's member ports for aggregation, the ARX and its peer can use LACP to automatically remove the port's link from the channel. If another configuration change makes the link suitable for aggregation again, the LACP processes can automatically restore it to the channel.

To establish LACP on the channel, enable active LACP at the peer and use this command on the ARX. If you connect two ARX peers over a channel (see [redundancy protocol \(cfg-channel\)](#)), you can use this command on both ARX peers to establish LACP; one of them assumes the active LACP role automatically.

The ARX-1500 and ARX-2500 only support active LACP; you can use the [lACP active](#) command to enable active LACP on those devices.

If LACP is disabled, all member ports remain in the channel no matter what configuration or topology changes occur later.

## ◆ Important

---

*The `no lACP passive` command restarts all of the channel's member ports. This stops all traffic on the channel for a brief time. This is not recommended for a busy channel; perform this operation only during off hours, or on an inactive channel.*

*For a channel used in a redundant-pair link (see the documentation for [redundancy protocol \(cfg-channel\)](#)), this causes the backup ARX to reboot. In most cases, the reboot has no effect on client traffic.*

**Guidelines (Cont.)** Use the [channel](#) command to create a channel, and use the [members \(cfg-channel\)](#) command to add a port to the channel. Each end of the channel should have the same LACP timeout settings; you can use the [lACP rate](#) command to change this end of the channel to a long timeout. The [show channel ... lACP](#) command shows the current configuration and status of LACP on a given channel. For LACP statistics, use the [show channel ... lACP stats](#) command (see the documentation for [show channel ... stats](#)).

**Samples** prt1ndA(cfg)# **channel 2**  
prt1ndA(cfg-channel[2])# **no lACP passive**

Warning: Disabling LACP will result in temporarily loss of network connectivity for all members of this channel.

Are you sure? [yes/no] **yes**  
stops LACP processing on channel 2.

bstnA(cfg)# **channel 1**  
bstnA(cfg-channel[1])# **lACP passive**  
starts LACP processing on channel 1.

**Related Commands** [channel](#)

---

# lacp rate

**Purpose** Link-Aggregation Control Protocol (LACP) is a control protocol for dynamically managing the member ports in a channel. The peers on both ends of the channel use LACP to exchange information about member ports; the peers can automatically remove or replace member links if configuration changes disqualify/re-qualify them for channel membership.

By default, the ARX uses a `Fast_Periodic_Time` for its transmissions (1 LACPDU each second), and a `Short_Timeout_Time` (time out if the peer takes longer than 3 seconds to respond). If the peer has different LACP timer settings, the peers may periodically disconnect from each other. Use the `lacp rate` command to lengthen the rate to one LACPDU every 30 seconds, and to lengthen the timeout to 90 seconds.

Use `no lacp rate` to return the timeout to its faster defaults.

**Mode** `cfg-channel`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `lacp rate long-timeout`  
`no lacp rate`

**Default(s)** `no lacp rate` -

- `Fast_Periodic_Time` - transmit an LACPDU once per second.
- `Short_Timeout_Time` - time out after 3 seconds.

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** The LACP timer settings should be the same at both ends of the channel.

This command is irrelevant unless you also use `lacp active` or `lacp passive` to enable LACP on the current channel.

This command disables and re-enables the channel to activate the change. The CLI prompts you with a warning about the temporary connection loss; enter `yes` to proceed.

LACP is defined in IEEE 802.3ad, and later in IEEE 802.1AX-2008. Channel peers configured with LACP can exchange Link Aggregation Control Protocol Data Units (LACPDU) over each member port. The peers can use the state information in these LACPDU to dynamically react to configuration or topology changes. For example, if a configuration change disqualifies one of the channel's member ports for aggregation, the ARX and its peer can use LACP to automatically remove the port's link from the channel. If another configuration change makes the link suitable for aggregation again, the LACP processes can automatically restore it to the channel.

These LACP timer settings are also defined in IEEE 802.1AX-2008. This command toggles between `Fast_Periodic_Time/Short_Timeout_Time` and `Slow_Periodic_Time/Long_Timeout_Time`.

Use the `channel` command to create a channel, and use the `members (cfg-channel)` command to add a port to the channel. The `show channel ... lacp` command shows the current configuration and status of LACP on a given channel. For LACP statistics, use the `show channel ... lacp stats` command (see the documentation for `show channel ... stats`).

**Sample** `bstnA(cfg-channel[1])# lacp rate long-timeout`

Warning: Changing the LACP Rate will result in temporarily loss of network connectivity for all members of this channel.

Are you sure? [yes/no] **yes**

sets a 30-second interval (and a 90-second timeout) for LACP transmissions on channel 1.

| <b>Syntax</b>           | <p><code>load-balance {src-ip   dst-ip   src-dst-ip}</code><br/> <code>no load-balance</code></p> <p><b>src-ip</b> uses only the packet's source-IP address in the hash. This may not produce the best hash: the source IPs are limited to a small set of VIPs (see <a href="#">virtual server</a>), proxy IPs (see <a href="#">ip proxy-address</a>), and management IPs (see <a href="#">ip address (cfg-if-vlan)</a> and <a href="#">ip address (cfg-mgmt)</a>).</p> <p><b>dst-ip</b> uses the packet's destination-IP address, ignoring the source address. Destination addresses are those of clients, filers, and management stations, so this is typically a better hash than one that uses the limited set of source IPs.</p> <p><b>src-dst-ip</b> combines the source and destination IPs with a bit-wise XOR operation. This hash typically produces the best traffic distribution within the channel.</p> |
| <b>Default(s)</b>       | <code>src-dst-ip</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Valid Platforms</b>  | ARX-2000 or ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>       | <p>This stops and restarts the channel to reset the traffic-distribution hash. The CLI therefore prompts for confirmation before stopping traffic; type <b>yes</b> to confirm.</p> <p>This is relevant to outbound traffic only.</p> <p>Use <code>show channel [load-balance]</code> to view the current load-balancing configuration for all channels. To find the results of the hash for a packet with a particular source and destination IP, use <code>show load-balancing</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Samples</b>          | <pre>bstnA(cfg-channel[9])# load-balance src-ip</pre> <p>Changing the load-balancing algorithm will cause the channel to disrupt traffic.</p> <pre>Are you sure? [yes/no] yes</pre> <p>uses source-IP addresses to choose outbound ports in channel 9. This ignores destination-IP addresses for the hash.</p> <pre>bstnA(cfg-channel[2])# no load-balance</pre> <p>Changing the load-balancing algorithm will cause the channel to disrupt traffic.</p> <pre>Are you sure? [yes/no] yes</pre> <p>returns channel 2 to the default; choose an outbound port based on an XOR of the packet's source and destination IPs.</p>                                                                                                                                                                                                                                                                                          |

## mac-address aging-time

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The ARX learns the MAC addresses of neighboring bridges by examining the source MACs in the frames that it receives. Each MAC address is added to (or updated in) an internal table of MAC addresses. If no new updates are received for a MAC address over the <i>aging time</i> , the switch erases a MAC address from the table. Use the <code>mac-address aging time</code> command to set the aging time.<br><br>Use the <code>no</code> form of the command to revert to the default aging time. |
| <b>Mode</b>             | cfg-stp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Valid Platforms</b>                                             | ARX-1500, ARX-2000, ARX-2500, and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Guidelines</b>                                                  | A channel can have up to 8 ports. All of the ports must be shut down before you add them with this command (see <code>shutdown (cfg-if-gig)</code> or <code>shutdown (cfg-if-ten-gig)</code> ). The ARX can support different speeds amongst the channel members; confirm that the peer at the other end of the channel can support this before you configure your channel this way.<br><br>For a channel to be used as a redundant-pair link, use the <code>redundancy protocol (cfg-channel)</code> command instead of this command.<br><br>You cannot use the <code>no members</code> command on the last port in the channel; instead, use <code>no channel</code> to remove the entire channel. |
| <b>Guidelines: Confirmation Prompt on an ARX-1500 and ARX-2500</b> | The ARX-1500 and ARX-2500 do not support the same VLAN on two physical interfaces, where a “physical interface” is either a port or a channel. Each VLAN can be carried by only one port or channel. Therefore, the system removes all VLANs from any member port you choose before adding the port to the channel. The port then carries the same VLAN(s) as the other ports in the same channel (with <code>vlan (cfg-channel)</code> or <code>vlan-tag</code> ). The CLI prompts for confirmation before taking the port off of any VLANs; enter <code>yes</code> to continue.                                                                                                                    |
| <b>Guidelines: Port 1/1 on an ARX-1500 and ARX-2500</b>            | On the ARX-1500 and ARX-2500, port 1/1 is the out-of-band management interface by default, and cannot be included in any client/server channel. If you prefer to use an in-band (VLAN) management interface (see <code>interface vlan</code> ) for accessing the CLI or GUI, you can use <code>interface mgmt</code> and <code>shutdown (cfg-mgmt)</code> to stop using port 1/1 for out-of-band management. Then you can use this command to include port 1/1 in a client/server channel.                                                                                                                                                                                                           |

**Samples**    `bstnA(cfg-channel[2])# members 2/7 to 2/10`  
                  adds ports 2/7-2/10 to channel 2.

`bstnA(cfg-channel[5])# members 2/2`  
                  adds port 2/2 (a ten-gigabit port) to channel 5.

`bstnA(cfg-channel[4])# no members 2/13 to 2/14`  
                  removes ports 2/13-2/14 from channel 4.

| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Syntax</b>           | <code>members slot/port [to slot/port ]</code><br><code>no members slot/port [to slot/port ]</code><br><br><i>slot/port</i> (2/1-14 on ARX-4000; 1/1-4 or 2/1-2 on ARX-2500; 1/1-12 on ARX-2000; 1/1-8 on ARX-1500) is the first (or only) Ethernet port.<br><i>to slot/port</i> (optional) is the last port in a range of ports. You cannot use this option on the ARX-2500 or ARX-1500, which allow only a single port to carry each VLAN.<br>Use the <a href="#">show interface</a> summary command to locate the slot(s) for these ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Valid Platforms</b>  | ARX-1500, ARX-2000, ARX-2500, and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Guidelines</b>       | IEEE 802.1Q defines VLANs.<br>This command adds ports to the VLAN with <i>tagging</i> disabled. A port with tagging disabled does not tag any outgoing frames with the VLAN ID (VID) for this VLAN. Use the <a href="#">tag</a> command to add ports with tagging enabled, or to enable tagging for existing VLAN ports.<br>On the ARX-1500 and the ARX-2500, only a single port ( <a href="#">interface gigabit</a> or <a href="#">interface ten-gigabit</a> ) or <a href="#">channel</a> can carry any given VLAN. That is, you can only select a single member port with this command. This includes VLAN 1; if multiple channels or ports default to VLAN 1, all but one of them must be disabled (with <a href="#">shutdown (cfg-if-gig)</a> , <a href="#">shutdown (cfg-if-ten-gig)</a> , or <a href="#">shutdown (cfg-channel)</a> ).<br>To assign a channel to carry the VLAN, use the <a href="#">vlan (cfg-channel)</a> command. On the ARX-2500 or ARX-1500, this is the method for carrying a VLAN on multiple ports; aggregate the ports into a <a href="#">channel</a> , then assign the desired VLAN to that channel. |

**Guidelines: Removing the Last Port from the Redundancy Link**

In the following circumstances, the `no members` command causes the backup ARX peer to reboot:

- the `interface vlan` command establishes an in-band (VLAN) management address for this VLAN,
- the `redundancy (cfg-if-vlan)` command establishes the above management address as the local end of the redundancy link,
- `redundancy` is active between the ARX peers, and
- the `no members` command is removing the last port(s) from the VLAN.

The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the `redundancy protocol`, `redundancy protocol (cfg-channel)`, or `redundancy (cfg-if-vlan)` command on another port, channel, or VLAN interface to establish a new redundant-pair link.

**Samples**

```
bstnA(cfg-vlan[1])# members 2/3 to 2/6
adds ports 2/3-2/6 to VLAN 1.
```

```
bstnA(cfg-vlan[5])# members 2/1
adds port 2/1 to VLAN 5.
```

```
bstnA(cfg-vlan[1])# no members 2/5 to 2/6
removes ports 2/5-2/6 from VLAN 1.
```

```
bstnA(cfg-vlan[7])# no members 2/11
removes port 2/11 from VLAN 7.
```

| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Guidelines</b>       | RST improves on the original STP implementation by more-rapidly converging on a new spanning-tree topology after a bridge or port failure. Conforming bridges (including the ARX) agree on the most-modern supported version of the protocol and use that version for all spanning-tree communication.<br><br>For an RST implementation, use the <code>cfg-if-gig <a href="#">spanning-tree edgeport</a></code> command to identify all the Edge Ports on the ARX. |
| <b>Samples</b>          | <code>bstnA(cfg-stp)# protocol dot1d</code><br>selects the earliest version of spanning-tree.<br><br><code>bstnA(cfg-stp)# no protocol</code><br>sets the protocol to the default, RST.                                                                                                                                                                                                                                                                            |

| <b>Guidelines</b>                                        | <p>At the layer-2 level, this establishes one end of the link between redundant peers. For best performance, a gigabit or ten-gigabit connection is strongly recommended; use the <code>speed (cfg-if-gig)</code> command to set the speed on a single-gigabit interface. We also recommend that the connection be direct (without any intervening bridges or routers), and that the switches are co-located. If the latency is low, an intervening Gigabit L2 switch is permissible.</p> <p>Alternatively, you can configure a multi-port channel as the redundant-pair link. Use <code>channel</code> to create the channel, then use <code>redundancy protocol (cfg-channel)</code> to add member ports to it. (The ARX-1500 and ARX-2500 use different commands to establish the redundancy link over a channel, described in the documentation for <code>redundancy protocol (cfg-channel)</code>.)</p> <p>For cases where low latency between the peers is impossible, you may need to increase a timeout value when you set up the redundant pair. When you set up <code>redundancy</code> between the peers later, you can use the <code>resilver-timeout</code> command to increase this timeout value. You can also use the <code>show redundancy metalog</code> command to monitor the latency between the peers.</p> |
| <b>Guidelines: Shutting Down the Redundant-Pair Link</b> | <p>The <code>no redundancy protocol</code> command disables the redundant-pair link (see <code>redundancy protocol</code>), and therefore causes the standby peer to reboot if redundancy is enabled (<code>enable (cfg-redundancy)</code>). The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the <code>redundancy protocol</code> or <code>redundancy protocol (cfg-channel)</code> command on another port or channel to establish a new redundant-pair link.</p> <p>The CLI prompts for confirmation before shutting down a redundant-pair link; enter <code>yes</code> to proceed with the interface shutdown and the reboot.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |

**Guidelines: ARX-1500 and ARX-2500**

The ARX-1500 and ARX-2500 use layer-3 (IP) networking software for exchanging heartbeats and important metalog data between the peers, so they require layer-3 configuration for their redundancy link. Instead of the layer-2 redundancy protocol command described here, you can use the following commands to set up a layer-3 redundancy link over the current interface:

- Establish a new VLAN for this link. Use the [vlan](#) command to create a new VLAN, then use [members \(cfg-vlan\)](#) to assign the current interface to that VLAN.
- Use the [interface vlan](#) to create a management-IP interface on the VLAN; this puts you into `cfg-if-vlan` mode.
  - From `cfg-if-vlan` mode, use the [ip address \(cfg-if-vlan\)](#) command to establish an in-band (VLAN) IP address. You later use this VLAN-management IP address to identify this ARX to its peer, as described below.
  - From the same mode, use [redundancy \(cfg-if-vlan\)](#) to designate the interface for exchanging metalog data and heartbeats.
  - From the same mode, use `no shutdown (cfg-if-vlan)` to enable the management interface.

**Samples**

```
prtlndA(cfg-if-gig[2/1])# redundancy protocol
 uses interface 2/1 as one end of a redundant-pair link.
```

```
bstnA(cfg-if-gig[2/13])# no redundancy protocol
Removing redundancy protocol for this interface will cause the peer to
reboot.
```

```
Are you sure? [yes/no] yes
 stops using interface 2/13 as one end of a redundant-pair link. If the redundant
 pair has already formed (see the enable \(cfg-redundancy\) documentation), this
 causes the peer to reboot.
```

```
bstnA(cfg-if-ten-gig[2/2])# redundancy protocol
 uses a ten-gigabit interface, 2/2, as one end of a redundant-pair link.
```

**Related Commands**

[interface gigabit](#)  
[interface ten-gigabit](#)  
[speed \(cfg-if-gig\)](#)  
[redundancy](#)  
[resilver-timeout](#)  
[show redundancy metalog](#)

## redundancy protocol (cfg-channel)

**Purpose** From `cfg-channel` mode, use the `redundancy protocol` command to add a single port or a range of ports to the current redundancy-link channel. This command performs two tasks at once: it adds ports to the channel, and prepares the channel for use as a redundant-pair link.

Use the `no redundancy protocol` command to remove redundancy-link support along with one or more ports.

**Mode** `cfg-channel`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `redundancy protocol slot/port [to slot/port ]`  
`no redundancy protocol slot/port [to slot/port ]`

*slot/port* (2/1-14 on ARX-4000; 1/1-12 on ARX-2000) is a single port or the first port in a range.

*to slot/port* (optional) is the last port in a range of ports.

Use the `show interface` summary command to locate the slot(s) for these ports.

**Default(s)** None

**Valid Platforms** ARX-2000 and ARX-4000

**Guidelines** A channel can have up to 8 ports. All ports must belong to the same VLAN(s) and they must run at the same speed.

Redundancy requires a reliable and fast channel for best performance. We recommend that you enable LACP on the channel to increase its reliability in high packet traffic: use `lacp passive` or `lacp active` to enable LACP, depending on your platform. For best performance, a gigabit (or higher-bandwidth) connection is strongly recommended. Use the `cfg-if-gig speed (cfg-if-gig)` command to set the speed on each port. We also recommend that the connection be direct (without any intervening bridges or routers), and that the switches are co-located. If the latency is low, an intervening Gigabit L2 switch is permissible.

For cases where low latency between the peers is impossible, you may need to increase a timeout value when you set up the redundant pair. When you set up `redundancy` between the peers later, you can use the `resilver-timeout` command to increase this timeout value. You can also use the `show redundancy metalog` command to monitor the latency between the peers.

A port cannot be a member of a channel if it has an “auto” speed.

Use the `members (cfg-channel)` command to add ports to a standard (non-redundancy-link) channel.

You cannot use the `no redundancy protocol` command on the last port in the channel; instead, use `no channel` to remove the entire channel.

**Guidelines: ARX-1500 and ARX-2500** The ARX-1500 and ARX-2500 use layer-3 (IP) networking software for exchanging heartbeats and important metalog data between the peers, so they require layer-3 configuration for their redundancy link. Instead of the layer-2 `redundancy protocol` command described here, you can use the following commands to set up a layer-3 redundancy link over the current channel:

- Establish a new VLAN for this link. Use the `vlan (cfg-channel)` command to assign the channel to the VLAN.
- Use the `interface vlan` to create a management-IP interface on the VLAN; this puts you into `cfg-if-vlan` mode.
  - From `cfg-if-vlan` mode, use the `ip address (cfg-if-vlan)` command to establish an in-band (VLAN) IP address. You later use this VLAN-management IP address to identify this ARX to its peer, as described below.
  - From the same mode, use `redundancy (cfg-if-vlan)` to designate the interface for exchanging metalog data and heartbeats.
  - From the same mode, use `no shutdown (cfg-if-vlan)` to enable the management interface.

**Samples** `bstnA(cfg-channel[2])# redundancy protocol 2/1 to 2/2`  
 adds ports 2/1-2/2 to channel 2, a channel to be used as a link between redundant peers.

`prt1ndA(cfg-channel[4])# no redundancy protocol 2/3`  
 removes port 2/3 from channel 4.

**Related Commands** `channel`  
`show interface summary`  
`speed (cfg-if-gig)`  
`members (cfg-channel)`  
`redundancy`  
`resilver-timeout`  
`show redundancy metalog`

## show channel

**Purpose** A *channel* is a group of Ethernet ports aggregated into a single flow, as specified in IEEE 802.3ad. Use the `show channel` command to show the configuration of one channel.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show channel {summary | load-balance | channel-id [lACP]}`

`summary` | `load-balance` | *channel-id* is a required choice.

- **summary** shows a summary for all channels.
- **load-balance** shows the load-balancing algorithm for all channels.
- ***channel-id*** (1-8) identifies one channel; use this option to show detailed parameters for one channel.

**lACP** (optional, if you choose a *channel-id*) displays the configuration and state of the Link Aggregation Control Protocol (LACP) on the given channel.

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, or ARX-4000

**Guidelines** This command shows the configuration and running state of a channel. Its various outputs are described below. For channel statistics (such as packet counts), use [show channel ... stats](#).

**Guidelines: Summary** The `show channel summary` command outputs one line per channel. Each line contains the following fields:

Ch Id identifies the channel.

\* indicates that the channel is used as a redundancy link with the switch's redundant peer (see [redundancy protocol \(cfg-channel\)](#)).

Admin State is set by the [shutdown \(cfg-channel\)](#) command.

Oper Status is Up if the channel has at least one operational port. This is Down if all of the member ports are down.

Speed is the speed of each port in the channel. Before ports can be aggregated into a channel, their speeds must match (see [speed \(cfg-if-gig\)](#) to set a port's speed).

Load-Balancing Algorithm shows the IP address(es) (source and/or destination) that are hashed to choose a port for an outbound packet. This is set by the [load-balance](#) command.

LACP is "Active," "Passive," or "Disabled," depending on the [lACP active](#) setting (on the ARX-1500 or ARX-2500), or the [lACP passive](#) setting (on other platforms that support channels).

Description is set by the [description \(cfg-channel\)](#) command.

**Guidelines: Load-Balance** The `show channel load-balance` command shows the load-balancing algorithm for each channel.

**Guidelines:**  
**channel-id (Detailed)**

The show channel *channel-id* command shows details about the given channel:

Channel Id identifies the channel.

Description is set by the [description \(cfg-channel\)](#) command.

Load Balancing Algorithm shows the IP address(es) or MAC address(es) (source and/or destination) that are hashed to choose a port for an outbound packet. This is set by the [load-balance](#) command.

LACP State is “Active,” “Passive,” or “Disabled.” LACP (Link Aggregation Control Protocol) is a control protocol for dynamically adapting member usage to topology changes. On some platforms, you can enable LACP “Passive” mode with the [lACP passive](#) command; on other platforms, you can use the [lACP active](#) command to enable LACP “Active” mode.

LACP Rate is either “Short Timeout” or “Long Timeout.” The rate should be the same at both ends of the channel, or the channel may periodically drop out of service. You can set this with the [lACP rate](#) command.

Members(Slot/Interface) lists the interfaces (ports) in this channel. Use the [members \(cfg-channel\)](#) command or the [redundancy protocol \(cfg-channel\)](#) command to add members to the channel.

Number of Members counts the ports from the above field.

Admin State is set by the [shutdown \(cfg-channel\)](#) command.

Channel Oper Status is Up if the channel has at least one operational port. This is Down if all of the member ports are down.

Trap Status is set by the [trap shutdown](#) command.

These spanning-tree fields only appear on systems that support the [spanning-tree](#) command.

- Spanning-Tree Forwarding State is “discard,” “forward,” or “disabled.” The channel is typically in “discard” state when the Spanning-Tree Role is “alternate,” and it is typically in “forward” state when the role is “designated” or “root.”
- Spanning-Tree State is enabled if the channel participates in the spanning tree. You can use the [spanning-tree shutdown](#) command to disable spanning tree for the channel.
- Spanning-Tree Role is the channel’s Port Role in the spanning tree: “root,” “designated,” or “alternate.”
- Accept Frames is “All” or “Tagged Only.” If this is the latter, the channel rejects all ingress frames unless they are tagged for one of the channel’s VLANs. “Tagged Only” appears if (and only if) the channel is used in a link between redundant peers; see [redundancy protocol \(cfg-channel\)](#).

Total Vlans Configured counts all VLANs in which this channel participates.

A small table of VLANs appears next, with one row for each VLAN on this channel. The table contains two columns:

Members VLAN ID is the VLAN (if any) where this channel is a member. The channel does not *tag* any outgoing frames with the VLAN ID (VID) for this VLAN.

Tag VLAN ID lists one or more VLANs (if any) where this channel is a tagging member; that is, this channel *tags* its outgoing frames with the VLAN ID (VID) for the destination VLAN.

**Guidelines:**  
**channel-id (Detailed),**  
**Cont.**

The next table contains the status of each member port, one per row. **Slot/Port** identifies each member port, and **Link Status** its status (up or down).

**Spanning-Tree Statistics** is a table of counters for the Bridge Protocol Data Units (BPDUs) transmitted and received. The counters are shown for two versions of spanning-tree BPDUs: original spanning tree (STP) or rapid spanning-tree (RST).

**Guidelines: lacp**

If you use the optional **lacp** argument in the command, the output shows LACP parameters and status for the chosen channel.

Three summary fields appear at the top of the output:

**Channel ID** identifies this channel

**LACP** is “Active,” “Passive,” or “Disabled,” depending on the **lacp active** setting (on the ARX-1500 or ARX-2500), or the **lacp passive** setting (on other platforms that support channels).

**Time since last state change** shows the time that has passed since the last change in channel membership or status.

This is followed by a table of **LACP Channel Parameters**. This table shows the channel-level configuration for LACP. It is divided into two columns: **Local** (for the ARX end of the channel) and **Peer** (for the remote end of the channel):

**Admin Key** is the numeric key for the channel that was set by its administrative configuration. A channel’s *key* is a number used by LACP software to identify the relevant configuration parameters of the channel. This is the same as the **Oper Key**, below, until or unless a configuration and/or topology change triggers a change in member-port usage. This field only appears in the **Local** column.

**Oper Key** is the numeric key that is currently in use for the channel. This key appears in both columns. The peer’s operational key is the one that was reported in the most-recent Link Aggregation Control Protocol Data Unit (*LACPDU*) from the peer.

**System Priority** shows the System Priority of the ARX and its peer. A lower number is considered a higher priority. The system with the higher priority initiates all port-membership changes in the channel, such as putting a port in “standby” status due to a configuration change. You can use the **priority (cfg-channel)** command to set the priority for the ARX end of the channel.

**System ID** is the MAC address used to identify the ARX and its peer.

The final section of the output, **LACP Port Parameters**, contains one table per channel member. Each table describes one port with its port-level LACP parameters and status. As above, these tables contain one **Local** column (for the ARX port) and a **Peer** column (for the corresponding port at the remote end of the channel). On the ARX-1500 and ARX-2500, this table contains the following fields:

**Slot/Port** identifies the ARX port. This information does not appear for the **Peer** port.

**Oper Key** is the key that is currently in use for this port. This number is a code that is only meaningful to the LACP software. It appears for both the local port and the peer port.

**Link Status** is either “up” or “down.” If this link is down, it is not being used for the channel’s traffic.

**Link Failure Count** shows the number of transmissions failures on this link, if any.

**Guidelines: LACP  
Output (Cont.)**

On all other platforms, the LACP Port Parameters table contains the following fields:

**Slot/Port** identifies the ARX port. This information does not appear for the Peer port.

**Admin Status** shows the administratively-set status of the member port. This only appears for an ARX port. Each port may have one or more of the following codes to signify its status:

- **A or P - A** (Active) means that the port is actively running LACP, and **P** (Passive) indicates that the port is sending LACPDUs but has not yet received proper responses from the peer.
- **T or L** - indicates the timeout between LACPDU transmissions. **T** is a short timeout (typically, 1 second) and **L** is a long timeout (typically 30 seconds).
- **a** - means that the port is eligible for Aggregation, or active use in the channel. Ports without this flag cannot be used in the channel; check the configuration at both ends for possible differences that make them incompatible.
- **S** - shows that the LACP process considers this port “in Sync” with its usage in the channel. If this flag is missing, it may indicate that the LACP software is in the process of changing the port from a “standby” state to an “active” one, or from active to standby.
- **C** - indicates that the port is Collecting packets. That is, it can accept incoming traffic.
- **D** - means that the port is Distributing packets. That is, it can send outbound packets to its peer.
- **d** - indicates that the port is using Default information for its peer’s operational key. This means that the peer’s configuration information on the ARX does not contradict the latest learned information from LACPDUs.
- **E** - indicates that the latest LACPDU has expired, and the LACP process is waiting for the next one.

**Oper State** is the current status of the port. This appears for both the Local port and its Peer. This has the same possible values as the **Admin Status**, described above.

**Admin Key** is a numeric key used by the LACP software as a code to represent the port’s capabilities. This key is based on administrative (CLI) settings. The LACP software may choose a different operational key (described below) for the port based on L2-topology changes or configuration changes at the peer port. This only appears for the ARX port, where administrative parameters are known.

**Oper Key** is the key that is currently in use for this port. This number is a code that is only meaningful to the LACP software. It appears for both the local port and the peer port.

**Port Priority** is a number that represents the port’s eligibility for use in the channel. A lower priority number represents a higher priority. If ports are excluded from active use in the channel, the LACP software prefers low-priority ports (that is, ports with higher-priority numbers). This appears for both the local and peer ports, and it may be different at both ends.

- Samples**
- stoweA# **show channel summary**  
shows a one-line summary for each channel. See [Figure 9.1](#) for sample output.
  
  - prtIndA# **show channel load-balance**  
shows the load-balancing algorithm for all channels on the “prtIndA” switch. See [Figure 9.2 on page 9-48](#) for sample output.
  
  - prtIndA# **show channel 1**  
shows the configuration for channel 1 on the same switch. See [Figure 9.3 on page 9-48](#) for sample output.
  
  - bstnA# **show channel 1 lacp**  
shows the LACP configuration for channel 1 on the “bstnA” switch. See [Figure 9.4 on page 9-49](#) for sample output.

## show channel ... stats

**Purpose** A *channel* is a group of Ethernet ports aggregated into a single flow, as specified in IEEE 802.3ad. Use the `show channel ... stats` command to show traffic statistics for one channel.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show channel channel-id [lACP] stats`

*channel-id* (1-8) identifies the channel to show.

**lACP** (optional) focuses the output on the Link Aggregation Control Protocol (LACP) statistics for the channel.

**stats** is a required keyword.

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** This command shows traffic statistics or Link Aggregation Control Protocol (LACP) statistics for a given channel. The sections below describe the two outputs from this command.

For configuration information about the channel, use [show channel](#). To clear the channel statistics in the default output, use [clear counters channel](#). To clear the LACP statistics, use [clear counters lACP](#).

**Guidelines: Traffic Statistics** If you omit the optional `lACP` keyword, the output focuses on frame counts for the overall channel.

Channel Id identifies the channel.

The statistics are divided into three tables:

- Basic Ingress and Egress statistics (primarily packet counts and error counts.)
- Statistics for MIB values from RFC 1493.
- Ethernet statistics.

**Guidelines: LACP Statistics**

If you use the `lACP` keyword, a table appears with LACP statistics. To enable LACP on a channel, you use the `lACP active` command on the ARX-1500 or ARX-2500, or the `lACP passive` command on other platforms that support channels.

Each table has a separate row for every member port in the channel, with the following columns:

**S/P** identifies the channel member in *slot/port* format.

**LACP Packets** are the numbers of Link Aggregation Control Protocol Data Units (*LACPDU*s) transmitted from and received on this member port.

**Marker Response** counts the LACP-marker frames transmitted and received. The LACP software sometimes injects *marker* frames to find the ends of one or more frame “conversations.” A *marker response* frame from the peer indicates that the conversation(s) is/are finished. Once the LACP software receives this marker, it can migrate future conversations to another link in the channel. For details on the Marker Protocol, see IEEE802.3ad, Section 43.5.

**Illegal** is the number of illegal Slow-Protocol PDUs (see IEEE802.3ad, Section 43B.4) received on this member port.

**Unknown** is the number of unknown Slow-Protocol PDUs received on this member port.

**Samples**

`prt1ndA# show channel 1 stats`

shows the statistics for channel 1. See [Figure 9.5](#) for sample output.

`bstnB# show channel 1 lacp stats`

shows the LACP statistics for channel 1 on a different switch. See [Figure 9.6 on page 9-53](#) for sample output.

## show interface gigabit

**Purpose** Use the `show interface gigabit` command to show the configuration of one Gigabit interface. Add the `stats` keyword to the end of the command to show the interface's traffic statistics.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show interface gigabit slot/port [stats]`

*slot/port* (2/3-14 on ARX-4000; 1/1-4 on ARX-2500; 1/1-12 on ARX-2000; 1/1-8 on ARX-1500; 1/2 on ARX-500; 1/1 on ARX-VE) specifies the interface.

**stats** (optional) displays statistics for this interface.

Use the [show interface summary](#) command to locate slots and ports.

**Guidelines** The default command shows a table of configuration settings.

The `stats` output is a table of counters, separated into Ingress and Egress counts. Use the [clear counters gigabit](#) command to clear and restart the statistics count.

**PAUSE Frames** are notices to control traffic flow: the [flowcontrol](#) command determines whether the interface sends or receives these.

These outputs are abbreviated for the ARX-VE platform. For example, on an ARX-VE the output does not include any references to flow control or storm control, which are managed at the hypervisor's vNIC.

**Samples** `bstnA> show interface gigabit 2/6`

shows the configuration for slot 2, port 6. See [Figure 9.7](#) for sample output.

`bstnA> show interface gigabit 2/6 stats`

shows the statistics for the same slot and port. See [Figure 9.8 on page 9-55](#) for sample output.

`stoweA> show interface gigabit 1/2`

shows the configuration for port 1/2 on an ARX-2500. See [Figure 9.9 on page 9-56](#) for sample output.

`stkbngA# show interface gigabit 1/1 stats`

shows the statistics for the only interface on an ARX-VE. As mentioned above, the statistics are abbreviated on this chassis type. See [Figure 9.9 on page 9-56](#) for sample output.

## show load-balancing

**Purpose** A *channel* is a group of Ethernet ports aggregated into a single flow, as specified in IEEE 802.3ad. Each channel uses a hash algorithm to balance the traffic load between its member ports; for each packet, the hash uses some combination of the source and destination IPs to choose a port. Use `show load-balancing` to show which port is used for a given source and destination IP.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show load-balancing source-ip src destination-ip dest channel chnl-id`

*src* is the source-IP address.

*dest* is the destination-IP address.

*chnl-id* (1-8) identifies the channel.

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** Use the `load-balance` command to change the algorithm for load-balancing a channel. Use this command to test the channel's current hash.

The output shows the **Slot Id** and **Interface** (port) that would be chosen for the source and destination IP that you provided.

**Sample** `prtInA# show load-balancing source-ip 172.16.100.98 destination-ip 192.168.25.23 channel 1`

shows the port that channel 1 uses for a packet with the given source and destination IPs. See [Figure 9.13](#) for sample output.

**Related Commands** [load-balance](#)

**Figure 9.13** Sample Output: `show load-balancing`

```
prtInA# show load-balancing source-ip 172.16.100.98 destination-ip 192.168.25.23 channel 1
```

```

| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines</b>       | <p>Mac Address Learning Mode is always IVL.</p> <p>MAC Address High Count and:</p> <p>Active MAC Addresses in FDB are counts of addresses in the Forwarding DataBase (FDB), the table that holds all MAC addresses.</p> <p>Maximum MAC Address Supported is fixed at 12,000.</p> <p>Configured Aging Time is the maximum time a learned MAC address is kept in the FDB without any updates; if a MAC address is not re-learned for this many seconds, it is deleted. Use the <code>mac-address aging-time</code> command to set the aging time.</p> <p>Use the <code>show mac-address-table</code> command to see all the MAC addresses in the FDB.</p> |
| <b>Related Commands</b> | <code>mac-address aging-time</code><br><code>show mac-address-table</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

*Figure 9.15 Sample Output: show mac-address-table summary*

```
bstnA> show mac-address-table summary

Mac Address Learning Mode IVL (Independent Vlan Learning)
MAC Address High Count 183
Active MAC Addresses in FDB 183
Maximum MAC Addresses Supported 12000
Configured Aging Time 300 secs
```

# show redundancy network

|                         |                                                                                                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>show redundancy network</code> command to show the layer-2 status of the redundant-pair link.                                                                                                  |
| <b>Mode</b>             | (any)                                                                                                                                                                                                        |
| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                                                                                                          |
| <b>Syntax</b>           | <code>show redundancy network</code>                                                                                                                                                                         |
| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                                                        |
| <b>Guidelines</b>       | This command shows an error unless at least one port has the <a href="#">redundancy protocol</a> setting, or one channel has ports added with the <a href="#">redundancy protocol (cfg-channel)</a> command. |

**Network** is “Client,” “Server,” “Private,” or “Metalog.” The redundant-pair link carries the Private and Metalog networks between the redundant peers.

**VLAN** is the VLAN number for this port. This does not appear on the ARX-500.

**Port(s)** are in *slot/port* format (for example, 2/9).

**Admin State** is “Enabled” or “Disabled.” You can set this with the `no shutdown (cfg-if-gig)` or the `no shutdown (cfg-if-ten-gig)` command.

**Link Status** is “Up” or “Down;” this is the link’s operational state.

**Spanning-Tree Status** is “Discard,” “Learning,” “Forward,” “Disabled,” “Manual Forwarding,” or “Not Participating.” This is the port’s current role in the spanning tree.

The Link Transitions table tracks any and all state/status transitions for redundancy-related ports:

**Count** is the total number of transitions. Use the `clear counters redundancy network` command to clear this counter.

**Last** is the date and time of the last transition.

**Reason** explains the nature and cause of the last transition.

**Last Cleared** is the last time someone used the `clear counters redundancy network` command.

**Related Commands** [clear counters redundancy network](#)

**Figure 9.16** Sample Output: `show redundancy network`  
 prtlnA# `show redundancy network`

| Network    | VLAN | Port(s) | Admin State | Link Status | Spanning-Tree Status |
|------------|------|---------|-------------|-------------|----------------------|
| External 1 | 1    | 1/1     | Enabled     | Down        | Disabled             |
| External 1 | 1    | 1/2     | Enabled     | Down        | Disabled             |
| External 1 | 1    | 1/3     | Enabled     | Down        | Disabled             |
| External 1 | 1    | 1/4     | Enabled     | Down        | Disabled             |
| External 1 | 1    | 1/5     | Enabled     | Up          | Manual Forwarding    |

Chapter 9  
Layer 2

---

|              |      |          |      |                   |
|--------------|------|----------|------|-------------------|
| External 1   | 1/6  | Enabled  | Up   | Manual Forwarding |
| External 1   | 1/7  | Disabled | Down | Disabled          |
| External 1   | 1/8  | Disabled | Down | Disabled          |
| External 1   | 1/9  | Disabled | Down | Disabled          |
| External 1   | 1/10 | Disabled | Down | Disabled          |
| External 1   | 1/11 | Disabled | Down | Disabled          |
| External 74  | 1/5  | Enabled  | Up   | Manual Forwarding |
| External 74  | 1/6  | Enabled  | Up   | Manual Forwarding |
| Private 1008 | 1/12 | Enabled  | Up   | Manual Forwarding |
| Metalog 1009 | 1/12 | Enabled  | Up   | Manual Forwarding |

Link Transitions:

Count: 3  
Last: 07:38:58 03/05/2010  
Reason: Port 1/5 link up  
Last Cleared: Never

## show spanning-tree interface

|                         |                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>show spanning-tree interface</code> command to show the spanning-tree configuration for a particular port.                                                        |
| <b>Mode</b>             | (any)                                                                                                                                                                           |
| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                                                                             |
| <b>Syntax</b>           | <code>show spanning-tree interface <i>slot/port</i></code>                                                                                                                      |
|                         | <i>slot/port</i> (2/1-14 on ARX-4000 or 1/1-12 on ARX-2000) is the slot and port number. Use the <a href="#">show interface</a> summary command to show all ports in all slots. |
| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                           |
| <b>Guidelines</b>       | This command shows the spanning-tree configuration parameters, the port's role in the spanning-tree topology, and some port statistics.                                         |
| <b>Related Commands</b> | <a href="#">spanning-tree</a>                                                                                                                                                   |

## show spanning-tree summary

**Purpose** Use the `show spanning-tree summary` command to show high-level information about the spanning-tree configuration.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show spanning-tree summary`

**Valid Platforms** ARX-2000 and ARX-4000

**Guidelines** Use the [show spanning-tree detailed](#) command to show details.

**Sample** `bstnA(cfg)# show spanning-tree summary`

```
Spanning Tree Admin State is Enabled
Configuration: Protocol : IEEE_Dot1w
 Revision Level : 0
 Format Selector : 0
Default : Name : 00-0A-49-00-13-02
Total MST Instances Created : 0
```

## show vlan summary

**Purpose** Use the `show vlan summary` command to list all configured VLANs.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show vlan summary`

**Valid Platforms** any *except* ARX-VE

**Guidelines** The sample output shows a table of configured VLANs:

Vlan ID identifies each VLAN.

Usage is: 'External' for VLANs used outside the box, 'Internal' for private VLANs inside the box, 'Private' for internal communications and communications with redundant peers, and 'Metalog' for metadata exchange between redundant peers.

Channel is set by assigning a channel to this VLAN (with `vlan (cfg-channel)` or `vlan-tag`). This is "N/A" if not set.

Frame/MTU is the packet size, set by `jumbo mtu`.

Description is set by the `description (cfg-vlan)` command.

Use the `show vlan` command to show details about a VLAN.

**Sample** `bstnA# show vlan summary`

Total VLANs Configured: 5

| VLAN ID | Usage    | Channel | Frame/MTU | Description           |
|---------|----------|---------|-----------|-----------------------|
| 1       | External | N/A     | Standard  | Default VLAN.         |
| 25      | External | N/A     | Standard  | personnel dept.       |
| 1010    | Private  | N/A     | Standard  | Private Subnet VLAN.  |
| 1011    | Metalog  | N/A     | Standard  | Private Metalog VLAN. |

**Related Commands** `description (cfg-vlan)`  
`show vlan`

| <b>Guidelines</b>       | <p>If this channel is used as a redundant-pair link (see <a href="#">redundancy protocol (cfg-channel)</a>) and redundancy is enabled (<a href="#">enable (cfg-redundancy)</a>), this command causes the standby peer to reboot. The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the <a href="#">redundancy protocol</a> or <a href="#">redundancy protocol (cfg-channel)</a> command on another port or channel to establish a new redundant-pair link.</p> <p>The CLI prompts for confirmation before shutting down a redundant-pair link; enter <code>yes</code> to proceed with the interface shutdown and the reboot.</p> |

| <b>Default(s)</b>                                        | <b>shutdown</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>                                        | <p>You cannot use this command on a channel member; use the <a href="#">shutdown (cfg-channel)</a> command to stop traffic on the channel.</p> <p>The ARX-1500 and ARX-2500 allow only a single logical interface (port or channel) to carry any given VLAN. That is, any VLAN can only be assigned to one port or channel (<a href="#">interface gigabit</a>, <a href="#">interface ten-gigabit</a>, or <a href="#">channel</a>). The CLI therefore prevents a <code>no shutdown</code> for any port on those chassis types if it carries a VLAN that is already assigned to an active channel or another active port. The CLI returns an error in this case, displaying the VLAN that has the conflict along with the active port(s) that already carry the VLAN. You can use <a href="#">show vlan n</a> to see the port or channel that carries VLAN <i>n</i>.</p>                                                                                              |
| <b>Guidelines: Shutting Down the Redundant-Pair Link</b> | <p>If this interface is the only one used as a redundant-pair link (through <a href="#">redundancy protocol</a> or <a href="#">redundancy (cfg-if-vlan)</a>) and redundancy is enabled (<a href="#">enable (cfg-redundancy)</a>), this command causes the standby peer to reboot. The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the <a href="#">redundancy protocol</a> or <a href="#">redundancy protocol (cfg-channel)</a> command on another port or channel to establish a new redundant-pair link.</p> <p>The CLI prompts for confirmation before shutting down a redundant-pair link; enter <b>yes</b> to proceed with the interface shutdown and the reboot.</p> |
| <b>Samples</b>                                           | <pre>bstnA(cfg-if-gig[2/4])# shutdown shuts down the current port, 2/4.</pre><br><pre>bstnA(cfg-if-gig[2/4])# no shutdown restarts the same port.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Guidelines</b>                                        | <p>You cannot use this command on a channel member; use the <a href="#">shutdown (cfg-channel)</a> command to stop traffic on the channel.</p> <p>The ARX-2500 allows only a single logical interface (port or channel) to carry any given VLAN. That is, any VLAN can only be assigned to one port or channel (<a href="#">interface gigabit</a>, <a href="#">interface ten-gigabit</a>, or <a href="#">channel</a>). The CLI therefore prevents a <code>no shutdown</code> for any port on those chassis types if it carries a VLAN that is already assigned to an active channel or another active port. The CLI returns an error in this case, displaying the VLAN that has the conflict along with the active port(s) that already carry the VLAN. You can use <a href="#">show vlan n</a> to see the port or channel that carries VLAN <i>n</i>.</p>                                             |
| <b>Guidelines: Shutting Down the Redundant-Pair Link</b> | <p>If this interface is used as a redundant-pair link (see <a href="#">redundancy protocol</a>) and redundancy is enabled (<a href="#">enable (cfg-redundancy)</a>), this command causes the standby peer to reboot. The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the <a href="#">redundancy protocol</a> or <a href="#">redundancy protocol (cfg-channel)</a> command on another port or channel to establish a new redundant-pair link.</p> <p>The CLI prompts for confirmation before shutting down a redundant-pair link; enter <b>yes</b> to proceed with the interface shutdown and the reboot.</p> |

| <b>Default(s)</b>       | <b>shutdown</b> : spanning tree is disabled (along with switch forwarding; see below) by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Valid Platforms</b>  | ARX-2000 and ARX-4000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Guidelines</b>       | <p>Before you can run <code>no shutdown</code> to start spanning-tree processing, you must use the <code>switch-forwarding enable</code> command. This permits the ARX to forward packets from one client/server port to another. By default, the ARX behaves as an end station rather than a bridge. The <code>switch-forwarding enable</code> command runs <code>no shutdown</code> as a side-effect; conversely, <code>no switch-forwarding enable</code> runs <code>shutdown</code> as a side-effect.</p> <p>If you shut down spanning tree, neighboring bridges must adjust the spanning-tree topology as though the ARX had been removed from the network.</p> |

### ◆ Important

---

*Spanning tree is activated along with switch forwarding to protect against possible network loops. You have the option to disable spanning tree while switch forwarding is active (using this command), but this is dangerous. Do not disable spanning tree unless you are confident that the ARX cannot create a loop.*

**Samples** `bstnA(cfg-stp)# shutdown`  
shuts down spanning tree.

`bstnA(cfg-stp)# no shutdown`  
restarts the spanning tree.

**Related Commands** [spanning-tree](#)  
[switch-forwarding enable](#)

| <b>Purpose</b>          | <p>The Spanning-Tree Protocol (STP) creates a loop-free topology in bridged networks. Use the <b>spanning-tree</b> command to configure the spanning-tree parameters on the ARX.</p> <p>Use the <b>no</b> form of this command to revert the spanning-tree parameters back to their defaults.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Guidelines</b>       | <p>The Spanning-Tree protocol is defined in IEEE 802.1D.</p> <p>Before the ARX can use STP, you must use the <a href="#">switch-forwarding enable</a> command. This permits the ARX to forward packets from one client/server port to another. By default, the ARX behaves as an end station rather than a bridge.</p> <p>The <b>spanning-tree</b> command puts you into <b>cfg-stp</b> mode, where you must set the protocol (STP or Rapid STP) with the <a href="#">protocol (cfg-stp)</a> command. There are several spanning-tree options you can set from <b>cfg-stp</b> mode, and there are some port-level options you can set from <b>cfg-if-gig</b> mode; see <i>Related Commands</i>, below.</p> <p>The <b>no</b> form of the command resets all global parameters to their respective defaults. The global parameters are the protocol, bridge Priority, Hello Time, Max Age, and Forward Delay.</p> |
| <b>Samples</b>          | <pre>bstnA(cfg)# <b>spanning-tree</b> bstnA(cfg-stp)#     enters cfg-stp mode.</pre> <pre>bstnA(cfg)# <b>no spanning-tree</b> bstnA(cfg)#     sets all global spanning-tree parameters to their default values.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## spanning-tree cost

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | IEEE 802.1D defines <i>Port Cost</i> as the relative cost to relay a frame to the root bridge. A lower cost is preferred. The port with the lowest cost is the <i>root port</i> for the ARX. Neighboring bridges compare the Port Costs of spanning-tree ports to <i>designate</i> one of them for their traffic. Use the <code>spanning-tree cost</code> command to set the Port Cost for the current port.<br><br>Use <code>no spanning-tree cost</code> to reset the Port Cost to the default. |

## spanning-tree priority

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | IEEE 802.1D defines <i>Port Priority</i> as the relative priority between ports with equal Port Costs. Neighboring bridges compare the Port Costs of spanning-tree ports to <i>designate</i> one of them for their traffic; if two or more Port Costs are the same, the protocol uses the Port Priority to break the tie. A lower number represents a higher priority. Use the <code>spanning-tree priority</code> command to set the Port Priority for the current port.<br><br>Use <code>no spanning-tree cost</code> to reset the Port Priority to the default. |

## spanning-tree shutdown

**Purpose** You can shut down spanning-tree processing on an individual port, thus removing the port from the spanning-tree topology. This stops the port from relaying frames from one LAN segment to another. You can also shutdown spanning tree for an aggregated channel. Use the `spanning-tree shutdown` command to shut down spanning tree at the current port or channel.

Use `no spanning-tree shutdown` to put the current port back into the spanning tree.

**Modes** `cfg-if-gig`  
`cfg-if-ten-gig`  
`cfg-channel`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `spanning-tree shutdown`  
`no spanning-tree shutdown`

**Default(s)** All ports and channels are part of the spanning tree by default.

**Valid Platforms** In `cfg-if-gig` mode or `cfg-channel`: ARX-2000 and ARX-4000.  
In `cfg-if-ten-gig` mode, ARX-4000 only.

**Guidelines** The Spanning-Tree protocol is defined in IEEE 802.1D.  
Use the [spanning-tree](#) command to configure spanning-tree on the ARX.  
You cannot use this command on a port or channel used in a redundant-pair link (see the documentation for the [redundancy protocol](#) and [redundancy protocol \(cfg-channel\)](#) commands).  
The ARX must be allowed to forward packets (with the [switch-forwarding enable](#) command) before you can use this command to enable spanning tree.

**Samples** `bstnA(cfg-if-gig[2/3])# spanning-tree shutdown`  
removes port 2/3 from the spanning tree.

`bstnA(cfg-channel[1])# spanning-tree shutdown`  
removes channel 1 from the spanning tree.

`bstnA(cfg-if-gig[2/3])# no spanning-tree shutdown`  
returns port 2/3 to the spanning tree.

`bstnA(cfg-if-ten-gig[2/2])# spanning-tree shutdown`  
removes port 2/2, a ten-gigabit port, from the spanning tree.

**Related Commands** [interface gigabit](#)  
[interface ten-gigabit](#)  
[channel](#)  
[spanning-tree](#)  
[switch-forwarding enable](#)

| <b>Related Commands</b> | <a href="#">interface gigabit</a><br><a href="#">show interface gigabit</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## switch-forwarding enable

**Purpose** By default, the ARX does not forward packets between its client/server ports; it behaves as an end station instead of a MAC bridge. Use the `switch-forwarding enable` command to enable packet forwarding and start using the ARX's bridging features. Use the `no` form of this command to stop all packet forwarding.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `switch-forwarding enable`  
`no switch-forwarding enable`

**Default(s)** `disabled`

**Valid Platforms** ARX-2000 and ARX-4000

**Guidelines** If switch forwarding is disabled, you cannot enable the `spanning-tree` protocol. When you enable switch forwarding with this command, spanning tree is enabled as a side-effect. Conversely, when you disable switch forwarding then spanning tree is disabled. The CLI warns you of these side-effects and prompts for confirmation; enter `yes` to proceed.

### ◆ Important

---

*Spanning tree is enabled along with switch forwarding to protect against possible network loops. You have the option to disable spanning tree while switch forwarding is active (using `shutdown (cfg-stp)`), but this is dangerous. Do not disable spanning tree unless you are confident that the ARX cannot create a loop.*

Use the `show version` command to see the current setting for this ARX.

**Samples** `bstnA(cfg)# switch-forwarding enable`  
Warning: Enable switch forwarding between all Ethernet Interfaces?  
This will also enable the Spanning Tree Protocol. [yes/no] `yes`  
`bstnA(cfg)#`

enables switch forwarding and spanning tree. This ARX can now behave as a MAC bridge.

`bstnA(cfg)# no switch-forwarding enable`  
Warning: Disable switch forwarding between all Ethernet Interfaces?  
This will also disable the Spanning Tree Protocol. [yes/no] `yes`  
`bstnA(cfg)#`

returns the "bstnA" switch to its default status. It no longer forwards packets from one client/server port to another.

**Related Commands** `spanning-tree`  
`show version`

---

## tag

**Purpose** A port with VLAN *tagging* enabled adds the VLAN ID (VID) to outbound frames, and only accepts ingress packets that are specifically tagged for the current VLAN. This is required to support multiple external VLANs. Use the **tag** command to add a single tag-enabled port or a range of tag-enabled ports to the current VLAN.

Use the **no** form of this command to disable tagging on a port(s).

**Mode** `cfg-vlan`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** **tag** *slot/port* [**to** *slot/port* ]  
**no tag** *slot/port* [**to** *slot/port* ]

*slot/port* (2/1-14 on ARX-4000; 1/1-4 or 2/1-2 on ARX-2500; 1/1-12 on ARX-2000; 1/1-8 on ARX-1500) is a single port or the first port in a range of ports.

**to** *slot/port* (optional) is the last port in a range of ports. You cannot use this option on the ARX-2500 or ARX-1500, which allow only a single port to carry each VLAN.

Use the [show interface](#) summary command to locate all slots and ports.

**Default(s)** None

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** IEEE 802.1Q defines VLANs.

If you select ports that were already configured as members of the VLAN, this command simply enables tagging on the selected ports. This means that incoming packets on those ports are not accepted as part of the current VLAN unless they are explicitly tagged with the VLAN's ID.

Use the [members \(cfg-vlan\)](#) command to add ports with tagging disabled.

A port can be a member of multiple VLANs, as long as each port is tagged for the VLANs. Use [vlan](#) to go into `cfg-vlan` mode for a VLAN, then use **tag** *slot/port* ... to tag some ports for that VLAN. You can repeat this for multiple VLANs, tagging the same set of ports for each.

To assign a channel to the VLAN with tagging enabled, use the [vlan-tag](#) command.

On the ARX-1500 and the ARX-2500, only a single port ([interface gigabit](#) or [interface ten-gigabit](#)) or [channel](#) can carry any given VLAN. That is, if you use this command to tag a port with a particular VLAN ID, you cannot tag any other port or channel with the same VLAN ID. This includes VLAN 1; if multiple channels or ports default to VLAN 1, all but one of them must be disabled (with [shutdown \(cfg-if-gig\)](#), [shutdown \(cfg-if-ten-gig\)](#), or [shutdown \(cfg-channel\)](#)).

**Guidelines: Removing the Last Port from the Redundancy Link**

In the following circumstances, the `no tag` command causes the backup ARX peer to reboot:

- the `interface vlan` command establishes an in-band (VLAN) management address for this VLAN,
- the `redundancy (cfg-if-vlan)` command establishes the above management address as the local end of the redundancy link,
- `redundancy` is active between the ARX peers, and
- the `no tag` command is removing the last port(s) from the VLAN.

The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with shutting down the link, you should establish a new one as soon as possible: use the `redundancy protocol`, `redundancy protocol (cfg-channel)`, or `redundancy (cfg-if-vlan)` command on another port, channel, or VLAN interface to establish a new redundant-pair link.

**Samples**

```
bstnA(cfg-vlan[1])# tag 2/3 to 2/5
adds ports 2/3-2/5, tagging enabled, to VLAN 1.
```

```
bstnA(cfg-vlan[1])# tag 2/6
adds port 2/6, tagging enabled, to VLAN 1.
```

```
bstnA(cfg-vlan[2])# no tag 2/7
disables tagging for port 2/7, VLAN 2. The port will not tag any outbound frames
destined for a MAC on VLAN 2.
```

## vlan

**Purpose** A Virtual Bridged Local Area Network (VLAN) is a group of physically-separated MAC addresses that appear as a single LAN segment. Devices on the same VLAN appear to be physically co-located even though some of the devices may be on different floors or different buildings. VLAN membership is often driven by human factors like departmental membership in a company. A VLAN often carries a single IP subnet. Use the `vlan` command to begin configuring a VLAN.

Use the `no` form of the command to remove a VLAN configuration.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `vlan vlan-id`  
`no vlan vlan-id`

*vlan-id* (1-4009) is an ID you choose for the VLAN. If the VLAN is already configured, this command edits its configuration.

**Default(s)** On all platforms except the ARX-1500, ARX-2500, and ARX-VE, the following VLANs are configured by default

- VLAN 1, which carries all client and server subnets.
- another VLAN to carry *private* IP traffic amongst the internal processes of the ARX.
- a third VLAN to carry *metalog* IP traffic amongst the internal processes of the ARX.

The ARX-1500 and ARX-2500 do not use internal VLANs for their private or metalog traffic.

**Valid Platforms** any *except* ARX-VE

**Guidelines** IEEE 802.1Q defines VLANs.

This command puts you into `cfg-vlan` mode, where you must configure at least one member port with either the `members (cfg-vlan)` command or the `tag` command. You can edit the ingress options for the VLAN members through some `cfg-if-gig` commands. See *Related Commands*, below, for a complete list of CLI options.

The ARX-1500 and ARX-2500 support only one port per VLAN. If you require multiple ports to carry a given VLAN on those chassis types, aggregate them into a `channel` and assign the VLAN to that channel with `vlan (cfg-channel)` or `vlan-tag`.

**Samples** `bstnA(cfg)# vlan 2`  
`bstnA(cfg-vlan[2])#`  
creates a configuration for VLAN 2.

`bstnA(cfg)# no vlan 18`  
removes the configuration for VLAN 18.

| <b>Guidelines</b>       | Before you assign a channel to a VLAN, the channel must have at least one member port (see <a href="#">members (cfg-channel)</a> ), and all members must be disabled ( <a href="#">shutdown (cfg-if-gig)</a> or <a href="#">shutdown (cfg-if-ten-gig)</a> ).<br>On the ARX-1500 and the ARX-2500, only a single port ( <a href="#">interface gigabit</a> or <a href="#">interface ten-gigabit</a> ) or channel can carry any given VLAN. That is, if you use this command to assign a VLAN to the current channel, you cannot assign the same VLAN to any other port or channel. This includes VLAN 1; if multiple channels or ports default to VLAN 1, all but one of them must be disabled (with <a href="#">shutdown (cfg-if-gig)</a> , <a href="#">shutdown (cfg-if-ten-gig)</a> , or <a href="#">shutdown (cfg-channel)</a> ).<br>A channel with VLAN <i>tagging</i> enabled adds a VLAN ID to every outgoing frame. Use the <a href="#">vlan-tag</a> command to enable VLAN tagging for the current channel. If VLAN tagging is disabled for the channel, the channel can belong to only one VLAN. |
| <b>Samples</b>          | <pre>bstnA(cfg-channel[1])# vlan 5</pre> assigns channel 1 to VLAN 5, untagged.<br><br><pre>bstnA(cfg-channel[7])# no vlan 2</pre> removes channel 7 from VLAN 2. If channel 7 did not have VLAN tagging set, it reverts to VLAN 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# vlan-tag

**Purpose** You can configure a channel to tag its outgoing packets with a VLAN ID, and to start accepting only explicitly-tagged ingress packets into the current VLAN. Channels with tagging enabled can support multiple VLANs; channels without tagging enabled can support only one. From `cfg-channel` mode, use the `vlan-tag` command to add a tagged VLAN to the current channel.

Use `no vlan-tag` to remove a tagged VLAN.

**Mode** `cfg-channel`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `vlan-tag vlan-id`  
`no vlan-tag vlan-id`

*vlan-id* (1-4095) identifies the VLAN to add or remove.

**Default(s)** channels belong to VLAN 1 by default.  
tagging disabled

**Valid Platforms** ARX-1500, ARX-2000, ARX-2500, and ARX-4000

**Guidelines** A channel with VLAN *tagging* enabled adds a VLAN ID to every outgoing frame. Repeat this command with different VLAN IDs to carry multiple VLANs on the channel. Once you tag the channel for one or more VLANs, it only accepts ingress frames that are explicitly tagged for one of the VLANs.

If you remove the last VLAN with the `no` form of this command, tagging is disabled for the channel and the channel is assigned to VLAN 1.

On the ARX-1500 and the ARX-2500, only a single port ([interface gigabit](#) or [interface ten-gigabit](#)) or channel can carry any given VLAN. That is, if you use this command to tag a channel with a particular VLAN ID, you cannot tag any other port or channel with the same VLAN ID. This includes VLAN 1; if multiple channels or ports default to VLAN 1, all but one of them must be disabled (with [shutdown \(cfg-if-gig\)](#), [shutdown \(cfg-if-ten-gig\)](#), or [shutdown \(cfg-channel\)](#)).

**Samples** `bstnA(cfg-channel[3])# vlan-tag 6`  
assigns channel 3 to VLAN 6 with tagging enabled.

`bstnA(cfg-channel[7])# no vlan-tag 2`  
removes channel 7 from VLAN 2. If channel 7 did not have another VLAN set for tagging, it reverts to VLAN 1 with no tagging.

## arp

**Purpose** The Address-Resolution Protocol (ARP) maps IP addresses to MAC addresses in an ARP table. Each network processor in the ARX has its own ARP table. Use the `arp` command to add a static entry to all ARP tables on the switch.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `arp ip-address mac-address [vlan vlan-id]`  
`no arp ip-address`

*ip-address* (for example, 10.125.16.3) is the IP address.

*mac-address* (for example, 12:34:56:78:9a:bc) is the MAC address you are statically mapping to the *ip-address*.

*vlan vlan-id* (optional; 0-4096) applies the mapping to a single VLAN.

**Default(s)** None

**Guidelines** The network processors are the ones behind the client/server interfaces, as well as the one behind the out-of-band MGMT interface.

Use the [show arp](#) command to show all ARP-table entries. Use the [clear arp](#) command to clear all dynamic-ARP entries, learned from neighboring equipment.

**Samples** `bstnA(cfg)# arp 192.168.25.38 11:54:d6:2a:95:f2`  
adds a static entry to the ARP table.

`bstnA(cfg)# arp 10.1.1.159 11:df:45:b3:95:36 vlan 4`  
adds a static entry to the ARP table and applies it to VLAN 4.

`bstnA(cfg)# no arp 172.16.209.55`  
removes an entry from the ARP table.

**Related Commands** [show arp](#)  
[clear arp](#)

## arp gratuitous

**Purpose** The Address-Resolution Protocol (ARP) maps IP addresses to MAC addresses in an ARP table. Each processor in the ARX has its own ARP table. Use the **arp gratuitous** command to issue gratuitous ARP entries for a single IP address or all IP addresses on the switch (including virtual IP addresses (VIPs), management IP addresses (MIPs), and proxy IP addresses (XIPs)).

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** **arp gratuitous {ip-address | yes}**

*ip-address* (0.0.0.0 to 255.255.255.255) is the IP address for which you want to add a gratuitous ARP entry. If there is an error, the system displays the error message on the CLI console.

**yes** specifies to add gratuitous ARP entries for all IP addresses owned by the switch. If there is an error, the system logs the error message (failed GARP) in the syslog.

**Default(s)** None.

**Guidelines** If you do not enter an IP address or **yes** at the end of this command, the switch sends a gratuitous ARP for all of its publicly-visible IP addresses (such as VIPs). Before sending all of this traffic, the CLI prompts for confirmation: enter **yes** to proceed.

Use the [show arp](#) command to show all ARP-table entries. Use the [clear arp](#) command to clear all dynamic-ARP entries, learned from neighboring equipment.

**Samples** bstnA# **arp gratuitous 192.168.25.38**  
sends a gratuitous ARP entry for one IP address.

```
bstnA# arp gratuitous
Send a gratuitous ARP for all of this switch's IP addresses? [yes/no]
yes
sends a gratuitous ARP for all IP addresses on the switch (VIPs, MIPs, and Proxy
IPs).
```

```
bstnA# arp gratuitous yes
also sends gratuitous ARPs for all IPs, but skips the prompt.
```

**Related Commands** [show arp](#)  
[clear arp](#)  
[arp](#)

---

## clear arp

**Purpose** The Address-Resolution Protocol (ARP) maps IP addresses to MAC addresses in an ARP table. ARP-table entries are either learned from neighbors (*dynamic*), set through the CLI (*static*), or set by internal software (*local*). Use the `clear arp` command to clear all dynamic entries from the ARP table.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `clear arp [from slot.processor]`

**from slot.processor** (optional) specifies one module processor. This option is not supported on the ARX-1500, ARX-2500, or ARX-VE. Each network-connected processor (the ones behind the client/server ports and the one behind the MGMT port) has its own ARP table.

*slot* (1-2 for an ARX-4000; 1 for all others) is the slot number.

*processor* is the processor number. Use the `show processors` command to show all processors and their associated *slot.processor* IDs.

**Default(s)** None

**Guidelines** Use the `show arp` command to show all ARP-table entries. Use the `arp` command to create a static-ARP entry.

**Samples** `bstnA# clear arp`  
clears all dynamic-ARP entries from the ARX.

`bstnA# clear arp from 2.2`  
clears the dynamic-ARP entries from processor 2.2 only.

**Related Commands** `show processors`  
`show arp`  
`arp`

|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Administrators can log into the CLI or GUI through the out-of-band (OOB) management interface. Port 1/1 is used as the OOB management interface on the ARX-1500 and ARX-2500. The <a href="#">show interface mgmt stats</a> command shows packet counters for this management interface. On the ARX-1500 or the ARX-2500, you can use the <code>clear counters mgmt</code> command to reset these counters to 0 (zero).                                                                                                                                                                                                                                                                         |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Platforms</b>        | ARX-1500 or ARX-2500                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Guidelines</b>       | <p>Use the <a href="#">show interface mgmt stats</a> command to show all ingress and egress counters for the out-of-band management interface.</p> <p>The ARX-1500 and the ARX-2500 can operate without using port 1/1 as an out-of-band management interface; you can use the <code>no interface mgmt</code> command to designate port 1/1 for client/server traffic instead of management traffic. If the port is not used for out-of-band management statistics, this command is unnecessary. You can use the <a href="#">show interface mgmt</a> command (with or without the <code>stats</code> option) to confirm that port 1/1 is designated as an out-of-band management interface.</p> |
| <b>Sample</b>           | <pre>stoweA# clear counters mgmt</pre> <p>clears all out-of-band-management counters from the current ARX.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## description (cfg-if-vlan)

**Purpose** You can configure one in-band management interface per VLAN. From `cfg-if-vlan` mode, use the optional `description` command to create a descriptive string for an in-band-management interface.

Use the `no` form of the command to delete the interface description.

**Mode** `cfg-if-vlan`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `description text`  
`no description`

*text* (up to 128 characters) is your description. Surround the text with quotation marks (“”) if it contains any spaces.

**Default(s)** No description

**Guidelines** The description appears in the [show interface vlan](#) command.

**Sample** `bstnA(cfg-if-vlan[1])# description “management for vlan 1”`  
specifies a description for the in-band-management interface on VLAN 1.

**Related Commands** [show interface vlan](#)

## description (cfg-mgmt)

**Purpose** An ARX (except the ARX-VE) can have one out-of-band management interface, on a separate IP network from all clients and servers. From `cfg-mgmt` mode, use the optional `description` command to create a descriptive string for the out-of-band management interface.

Use the `no` form of the command to delete the interface description.

**Mode** `cfg-mgmt`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `description text`  
`no description`

*text* (up to 128 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** `no description`

**Platforms** any *except* ARX-VE

**Guidelines** The description appears in the [show interface mgmt](#) command.

**Sample** `bstnA(cfg-mgmt)# description "oob management"`  
specifies a description for the management interface.

**Related Commands** [show interface mgmt](#)

| <b>Guidelines</b>                                          | <p>The ARX software keeps a separate IP routing table for its out-of-band management interface; this network is designed to be completely separate and disjoint from any client or server subnets. This interface is designed for installations with a separate subnet exclusively for management use.</p> <p>This command puts you into <code>cfg-mgmt</code> mode, where you can set several configuration parameters for the management interface. Use the <a href="#">ip address (cfg-mgmt)</a> command to change the IP address. Use the <a href="#">description (cfg-mgmt)</a> command to set an optional description for the interface, for show commands. Use the <a href="#">shutdown (cfg-mgmt)</a> command to shut down the interface.</p> <p>To show the configuration of the management interface, use <a href="#">show interface mgmt</a>.</p> <p>To set up an in-band management interface for one or more VLANs, use the <a href="#">interface vlan</a> command.</p> <p>You cannot use <code>no interface mgmt</code> if you are logged into the CLI through the out-of-band management interface; this would abruptly end your CLI session. The CLI also prevents <code>no interface mgmt</code> if the ARX has <a href="#">redundancy</a> configured; on many platforms, this interface is used for important redundancy-related traffic.</p> |
| <b>Guidelines: ARX-1500 and ARX-2500</b>                   | <p>On the ARX-1500 and ARX-2500, port 1/1 is set up as the out-of-band management interface by default. For installations with no separate management subnet, you can use the <code>no interface mgmt</code> command to stop using port 1/1 for out-of-band management. You can then edit the port as a standard client/server interface with the <a href="#">interface gigabit 1/1</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Guidelines: No Out-of-Band Management on the ARX-VE</b> | <p>The ARX-VE is a Virtual Appliance (VA) that only uses a single VNIC, so it only has an in-band management interface. This command is therefore unavailable in the ARX-VE CLI.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Purpose</b>          | You can configure one in-band management interface per supported VLAN. Use the <code>interface vlan</code> command to begin configuring the management interface for a VLAN. Use the <code>no</code> form to remove the in-band-management interface for a VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Use the <a href="#">show vlan summary</a> command for a list of all configured VLANs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Guidelines</b>       | <p>This command puts you into <code>cfg-if-vlan</code> mode, where you can set several configuration parameters for the in-band management interface. Use the <a href="#">ip address (cfg-if-vlan)</a> command to set the IP address. Use the <a href="#">description (cfg-if-vlan)</a> command to set an optional description for the interface, for show commands. Use the <a href="#">shutdown (cfg-if-vlan)</a> command to shut down the interface.</p> <p>You can re-use this interface as a connection to the switch's redundant peer and/or to multiple switches on the same RON. The <a href="#">redundancy (cfg-if-vlan)</a> command makes the interface eligible for the initial rendezvous with a redundant peer; this command is required for the ARX-1500 and ARX-2500, which use this layer-3 connection for exchanging heartbeats and metalog data. The <a href="#">ron tunnel</a> command enters a sub-mode for configuring a RON tunnel to another ARX.</p> <p>To show the configuration of the management interface, use <a href="#">show interface vlan</a>.</p> |
| <b>Sample</b>           | <pre>bstnA(cfg)# interface vlan 9 bstnA(cfg-if-vlan[9])#</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Related Commands</b> | <a href="#">show vlan summary</a><br><a href="#">ip address (cfg-if-vlan)</a><br><a href="#">description (cfg-if-vlan)</a><br><a href="#">shutdown (cfg-if-vlan)</a><br><a href="#">show interface vlan</a><br><a href="#">redundancy (cfg-if-vlan)</a><br><a href="#">ron tunnel</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## ip address (cfg-if-vlan)

**Purpose** Administrators can use the in-band management address to log into the CLI or GUI from a client or server VLAN. From `cfg-if-vlan` mode, use the `ip address` command to set the address for the current VLAN's in-band management interface. Use the `no` form of this command to remove the IP address and disable the interface.

### ◆ Important

---

*In a redundant pair of ARXes, the network software uses an in-band (VLAN) management address as a home address for its communication with the [quorum-disk](#). Without an in-band-management address and an [ip route](#) to the quorum disk, a failover is impossible. Additionally, any [ron tunnels](#) that use this address will fail if you remove it; a [shadow-copy-rule](#) depends on RON tunnels to communicate with other ARXes in the network. Use the `no` form of the command only on the advice of F5 Support.*

**Mode** `cfg-if-vlan`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip address address mask`  
`no ip address`

*address* is the IP address you choose for the VLAN-management interface (for example, 192.168.108.223).

*mask* defines the network part of the address (for example, 255.255.255.0).

**Default(s)** None

**Guidelines** An ARX in a redundant pair requires an in-band (VLAN) management address with an IP route to its quorum disk. This is required so that the ARX can reach its quorum disk while in the backup role. Refer to the [quorum-disk](#) documentation for more details. Do not delete this address if this ARX has a quorum disk on the current VLAN.

A redundant pair of ARX-2500 or ARX-1500 devices requires an in-band (VLAN) management interface for each end of the redundancy link. The redundancy link is the channel (or possibly single link) that connects the redundant ARX devices. The IP address that you assign to the redundancy link (with this command) is used in the [peer](#) command when you join the redundant pair.

If the current in-band (VLAN) interface is the end point for one or more RON tunnels, those tunnels also depend in this IP address.

**Sample** `bstnA(cfg-if-vlan[9])# ip address 192.168.25.28 255.255.255.0`  
sets an in-band management IP for VLAN 9.

**Related Commands** [interface vlan](#)  
[quorum-disk](#)  
[peer](#)  
[ron tunnel](#)

## ip address (cfg-mgmt)

**Purpose** Administrators can use the out-of-band management address to log into the CLI. This is configured as part of the initial-boot process. From `cfg-mgmt` mode, use the `ip address` command to change the address for the out-of-band management interface. Use the `no` form of this command to remove the IP address and disable the interface.

**Mode** `cfg-mgmt`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip address address mask`  
`no ip address`

*address* is the IP address you choose for the management interface (for example, 10.1.1.10).

*mask* defines the network part of the address (for example, 255.255.255.0).

**Default(s)** None

**Platforms** any *except* ARX-VE

**Guidelines** This address must belong to a management network that is entirely distinct from any client subnet (established with [virtual server](#)) or the proxy-IP subnet (created by [ip proxy-address](#)). The MGMT interface uses a separate IP-routing table; use the [ip route ... mgmt](#) command to specify a default route (or any other static route) for the out-of-band management network.

**Samples** `bstnA(cfg-mgmt)# ip address 10.1.1.7 255.255.255.0`  
sets an out-of-band management IP for the ARX.

`bstnA(cfg-mgmt)# no ip address`  
removes the IP configuration from the out-of-band management interface.

**Related Commands** [interface mgmt](#)  
[ip route](#)

---

# ip domain-list

**Purpose** You can create an optional *search list* of domain names for the ARX to use in its DNS lookups. Whenever the switch needs to perform a DNS lookup for a hostname (for example, “fs5”), it appends a domain name (for example, “mycompany.com”) and tries a DNS lookup; on failure, it appends the next domain name in the list; and so on. Use the `ip domain-list` command to add one domain name to the search list.

Use the `no` form of this command to remove a domain name from the search list.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip domain-list name`  
`no ip domain-list name`

*name* (1-255 characters) is a name for one local domain (for example, “myorg.org”).

**Default(s)** `None`

**Guidelines** The search list is analogous to the “search” list in an `/etc/resolv.conf` file. You can enter this command multiple times, once for each search domain. The search domains are concatenated together, separated by spaces: the total length of this domain list cannot exceed 256 characters.

To identify a DNS server, use the [ip name-server](#) command. Use the [show ip domain](#) command to view the current DNS-lookup configuration.

**Samples** `bstnA(cfg)# ip domain-list estorage.com`  
`bstnA(cfg)# ip domain-list enet.com`  
adds two domain names to the search list. The ARX will try “estorage.com” first when it looks up short names.

`bstnA(cfg)# no ip domain-list enet.com`  
removes one domain name from the search list.

**Related Commands** [ip name-server](#)  
[show ip domain](#)

## ip name-server

**Purpose** This command identifies a DNS server that the ARX can use for DNS lookups. You can enter up to three DNS servers. Use the `ip name-server` command to add a DNS server.

Use the `no` form of this command to remove a DNS server from the list.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip name-server ip-address`  
`no ip name-server ip-address`

*ip-address* identifies a DNS server (for example, “172.16.98.36”). This address must be on the server/proxy-IP subnet (see [ip proxy-address](#)) or reachable through a static route (see [ip route](#)).

**Default(s)** None

**Guidelines** You can enter this command multiple times, once for each DNS server; the switch supports a maximum of three. The servers are queried in the order that you enter them. The ARX switches from one DNS server to another if (and only if) the server is unreachable.

To support lookups of hostnames (for example, “myserver” instead of “myserver.mycompany.com”), you can declare one or more local domains (such as “mycompany.com”) for the switch with the [ip domain-list](#) command.

All of the DNS servers should provide service for the same set of networks and domains.

Use the [show ip domain](#) command to view the current DNS-lookup configuration.

**Samples** `bstnA(cfg)# ip name-server 192.168.25.201`  
identifies a DNS server.

`bstnA(cfg)# no ip name-server 192.168.25.212`  
removes one DNS server from the list.

**Related Commands** [ip proxy-address](#)  
[ip route](#)  
[ip domain-list](#)  
[show ip domain](#)

---

# ip proxy-address

**Purpose** Every NSM processor requires a *proxy IP* address to communicate with back-end devices. Use the `ip proxy-address` command to add a range of proxy IPs. Use the `no` form of the command to remove a range of unused proxy-IP addresses.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip proxy-address address mask [vlan vlan-id] [count number] [processor slot.proc]`  
`no ip proxy-address address`

*address* is the starting IP address for a range of proxy IPs (for example, 192.168.25.0).

*mask* is the subnet mask (for example, 255.255.255.0).

`vlan vlan-id` (optional, 1-65535) is the VLAN for this subnet, if there is one. Use [show vlan summary](#) for a complete list of configured VLANs.

`count number` (optional, 1-64) is the number of contiguous IP addresses to assign to the proxy pool.

`slot.proc` (optional: for example, 1.4) assigns the proxy-IP address to a particular NSM processor. You can only use this option if you specify a single IP.

**Default(s)** *vlan-id* defaults to VLAN 1.  
*number* defaults to 1.

**Guidelines** You must configure one proxy-IP address per network processor, where

- the ARX-VE and ARX-500 each have 1,
- the ARX-1500 has 2,
- the ARX-2000 has 4,
- the ARX-2500 has 3 (or 4, depending on the setting for [resource-profile](#)), and
- the ARX-4000 has 12.

The proxy IP addresses must all belong to the same subnet, but do not need to be contiguous. You can use this command multiple times to define multiple ranges, as long as there are enough proxy IPs for all of the network processors.

Be sure to assign the correct proxy-IP addresses the first time. Once the proxy IP is assigned to an NSM processor, it is difficult to change. To change an assigned proxy IP, you must save your configuration (with the `priv-exec copy startup-config` command), remove it from the switch (`delete startup-config`), reboot (`reload`), edit the saved configuration with the correct proxy-IP addresses, and replay it (that is, copy it and paste it into the CLI). The CLI prompts for confirmation before making any change to the proxy-IP addresses; please examine your proxy-IP change carefully before you enter `yes` to proceed.

**Sample** bstnA(cfg)# ip proxy-address 192.168.25.31 255.255.255.0 vlan 25 count  
4  
%WARNING: The IP proxy address changes will take effect,  
and cannot be modified without clearing your startup-config.

The ip proxy-address configuration will be 4 proxy-address(es)  
starting at IP 192.168.25.31 on VLAN 25.

Continue? [yes/no] yes  
bstnA(cfg)# ip proxy-address 192.168.25.141 255.255.255.0 vlan 25 count  
8  
%WARNING: The IP proxy address changes will take effect,  
and cannot be modified without clearing your startup-config.

The ip proxy-address configuration will be 8 proxy-address(es)  
starting at IP 192.168.25.141 on VLAN 25.

Continue? [yes/no] yes  
configures two ranges of proxy-IP addresses, for a total of 12.

**Related Commands** [show vlan summary](#)

---

# ip route

**Purpose** Use the `ip route` command to configure a static IP route.  
Use the `no` form of this command to remove a static route.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip route ip-subnet ip-mask gateway [distance] [mgmt]`  
`no ip route ip-subnet ip-mask gateway [distance] [mgmt]`

*ip-subnet* is the IP address of a remote subnet (for example, 172.16.151.0).

*ip-mask* defines the network part of the subnet (for example, 255.255.255.0).

*gateway* identifies the gateway to the subnet (for example, 192.168.25.1).

*distance* (optional; 1-255) is an arbitrary distance metric; if you configure two routes to the same subnet, the route with the lowest distance is used.

*mgmt* (optional) is a flag that adds the route to a separate routing table for the out-of-band management network. This option is not available on the ARX-VE, which does not have a separate out-of-band management interface. Also, the option does not apply to any ARX-1500 or an ARX-2500 where port 1/1 is being used for client/server traffic.

**Default(s)** *distance* - 128

**Guidelines** Configure a static route for every IP subnet with clients or servers that is outside any client subnet (defined by the [virtual server](#) command) or the proxy-IP subnet (see [ip proxy-address](#)). For a remote client subnet, the next-hop gateway must be in the subnet where their VIP resides. Similarly, a route to a remote server network must go through the proxy-IP subnet.

The ARX keeps a separate routing table for the out-of-band management interface. This management interface connects to a separate IP network, and therefore requires a routing table that is tailored to its network. Use the **mgmt** flag to add or remove a route from this table. The gateways for these routes must be on the management subnet defined by the [ip address \(cfg-mgmt\)](#) command.

You can also use multiple static routes to the same destination, each with different next hops. You can use different *distance* costs with each route to indicate your route preferences.

If the ARX has a redundant peer, you can use the [critical route](#) command to designate that a route is critical. If a critical route fails, the ARX may fail over to its peer.

Use the [show ip route](#) command to list all static routes, including the routes in the separate table for management routes.

**Samples**    `bstnA(cfg)# ip route 172.16.231.0 255.255.255.0 192.168.25.1`  
creates a static route to a client subnet.

`bstnA(cfg)# ip route 172.16.231.0 255.255.255.0 192.168.25.2 255`  
creates another static route to the same subnet. The distance is set very high, so this route would not be chosen unless the gateway fails for the previous route.

`bstnA(cfg)# ip route 10.16.10.0 255.255.255.0 10.1.1.1 mgmt`  
creates a static route for the out-of-band management network.

`bstnA(cfg)# no ip route 10.16.165.0 255.255.255.0 10.1.1.1 mgmt`  
removes a static route for the out-of-band management network.

---

## ip route ... per-vlan

**Purpose** Some installations have a firewall between the ARX and its clients, and require VIPs on multiple client VLANs. In those situations, the ARX's single default route (created with the [ip route](#) command) causes the ARX to send all response packets over the default route's VLAN. If that VLAN is not the same as the VIP's VLAN, the firewall may drop the response packet. For example, if there are VIPs on each of VLANs A, B, and C, the single default route can only go over one of those VLANs (for example, VLAN A). Clients from the other VLANs (B and C) would send requests to those VLANs and get responses from VLAN A. If the firewall is connected to each VLAN through different interfaces, the response packet arrives on a different interface than the request packet. A firewall drops such packets, with different source and destination interfaces. To solve this specific problem, on the advice of F5 Support, you can use the [ip route ... per-vlan](#) command to make a separate default route for each client VLAN. Use the `no` form of this command to remove a VLAN-specific-default route.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip route 0.0.0.0 0.0.0.0 gateway [distance] per-vlan vlan-id`  
`no ip route 0.0.0.0 0.0.0.0 gateway [distance] per-vlan vlan-id`

`0.0.0.0 0.0.0.0` is the IP subnet and mask for a default route. You cannot define a subnet-specific route on a per-VLAN basis.

`gateway` identifies the gateway to use for this VLAN (for example, 192.168.30.1).

`distance` (optional; 1-255) is an arbitrary distance metric; if you configure two routes to the same subnet, the route with the lowest distance is used.

`per-vlan vlan-id` (0-4096) identifies the VLAN for this default route. You must choose a VLAN that is already defined on the ARX; use [show vlan summary](#) for a list of defined VLANs, and use [vlan](#) to define a new one.

**Default(s)** `distance - 128`

**Platforms** ARX-500, ARX-2000, ARX-4000, and ARX-VE

**Guidelines** Use this command only on the advice of F5 Support. A standard `ip route` has some features (listed below) that are not supported for the per-VLAN route.

Because of this route's limitations, the CLI prompts for confirmation before it accepts the per-VLAN route; enter `yes` to continue.

If a client request arrives over a VLAN without a per-VLAN-default route, the response goes over the ARX's default route (defined with the standard [ip route](#) command).

This command is not available on the ARX-1500 or ARX-2500. The [ip route ... source-ip](#) command performs a similar function for those platforms.

- Guidelines:** As mentioned above, this type of default route has several limitations.
- Limitations**
- You cannot create a per-VLAN route to a specific subnet. This is always a default route.
  - You cannot designate a per-VLAN route as a **critical route**, as you can with a standard IP route. If you lose connectivity to the **gateway**, the ARX does not fail over to its peer (which may have a better connection).
  - Unlike a standard default route, you are limited to a single **gateway** for each VLAN. For a standard default route, you can enter multiple **ip route** commands with different gateways and different values for **distance**. The ARX attempts to reach the gateway with the lowest distance value and tries a higher-distance gateway if the first is unreachable. This form of the command does not support a **distance** value, so you cannot establish redundant gateways for the VLAN's default route.
  - This type of default route is used only for outbound IP packets where a VIP is the source address. (The **virtual server** command creates a VIP.)

**Samples** bstnA(cfg)# **ip route 0.0.0.0 0.0.0.0 192.168.76.1 1 per-vlan 38**

This static route overrides the default route for the specified VLAN. The route does not support health checks.

Do you want to continue? [yes/no] **yes**

creates a default route for VLAN 38 with the lowest possible distance metric, 1. Responses to packets from this VLAN go back out over the same VLAN.

prtlndB(cfg)# **no ip route 0.0.0.0 0.0.0.0 per-vlan 99**

Removing this route will result in the global default route being used for this VLAN.

Do you want to proceed? [yes/no] **yes**

removes the default route for VLAN 99. Responses to packets from this VLAN use the default route designated by the standard **ip route** command.

## ip route ... source-ip

**Purpose** Some installations have a firewall between the ARX and its clients, and require VIPs on multiple client VLANs. In those situations, the ARX's single default route (created with the [ip route](#) command) causes the ARX to send all response packets over the default route's VLAN. If that VLAN is not the same as the VIP's VLAN, the firewall may drop the response packet. For example, if there are VIPs on each of VLANs A, B, and C, the single default route can only go over one of those VLANs (for example, VLAN A). Clients from the other VLANs (B and C) would send requests to those VLANs and get responses from VLAN A. If the firewall is connected to each VLAN through different interfaces, the response packet arrives on a different interface than the request packet. A firewall drops such packets, with different source and destination interfaces. To solve this specific problem on an ARX-1500 or ARX-2500, you can use the `ip route ... source-ip` command to make a separate default route for each VIP; any packet received at the VIP uses this default route with the same VIP as its source IP.

Use the `no` form of this command to remove a VIP-specific-default route.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ip route 0.0.0.0 0.0.0.0 gateway [distance] source-ip vip`  
`no ip route 0.0.0.0 0.0.0.0 [gateway] [distance] source-ip vip`

`0.0.0.0 0.0.0.0` is the IP subnet and mask for a default route. You cannot define a subnet-specific route on a per-VIP basis.

`gateway` identifies the gateway to use for this route (for example, 192.168.30.1).

`distance` (optional; 1-255) is an arbitrary distance metric; if you configure two routes to the same subnet, the route with the lowest distance is used.

`source-ip vip` identifies the VIP for this default route. You must choose a VIP that is already defined on the ARX; use [show global server](#) for a list of defined VIPs, and use the [virtual server](#) command to define a new one.

**Default(s)** `distance` - 128

**Platforms** ARX-1500 or ARX-2500

**Guidelines** This command only functions on the ARX-1500 or ARX-2500. The [ip route ... per-vlan](#) command performs a similar function on all other platforms.

If a client request arrives at a VIP without a per-VIP-default route, the response goes over the ARX's default route (defined with the standard [ip route](#) command).

**Samples** canbyA(cfg)# **ip route 0.0.0.0 0.0.0.0 192.168.121.1 1 source-ip 192.168.121.76**  
creates a default route for VIP 192.168.121.76 with the lowest possible distance metric, 1. Responses to packets from this VIP go back out over the same VIP.

stoweA(cfg)# **no ip route 0.0.0.0 0.0.0.0 192.168.90.1 source-ip 192.168.90.29**  
removes the default route for VIP 192.168.90.29. Responses to packets from this VIP use the default route designated by the standard [ip route](#) command.

## ntp server

**Purpose** The ARX can synchronize its internal clock with an external Network Time Protocol (NTP) server. Use the `ntp server` command to identify an NTP server.  
Use the `no` form of this command to disconnect from an NTP server.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `ntp server ip-address [version {3 | 4}]`  
`no ntp server ip-address`

*ip-address* (1-128 characters) identifies the external NTP server by its IP address.

---

### ◆ Note

*Windows Domain Controllers (DCs) support NTP and can be used as NTP servers. You should only use a DC as your NTP server if all the back-end CIFS filers also use the DC in this way.*

**version {3 | 4}** (optional) is the NTP version to use, NTPv3 or SNTPv4.

**Default(s)** `version - 4` (SNTPv4)

**Guidelines** Use the same NTP servers for the ARX that you use for the back-end filers and front-end clients. For namespace policy it is vital that the ARX is synchronized with the back-end servers; it is also required for installations that use Kerberos. Note that synchronization is more important than time accuracy; if all the servers agree on the wrong time, policy and Kerberos continue to function.

The default protocol for external NTP communication is Simple NTP (SNTP) v4, defined in RFC 2030. If you set the version to v3, the switch uses NTPv3 defined in RFC 1305.

You can repeat this command to configure up to 8 NTP servers. The switch selects the best server as specified by the NTP protocol.

Use [show ntp servers](#) to see the current NTP configuration. Use [show clock](#) to see the current time/date setting on the ARX.

You can set the internal clock manually with the [clock set](#) command. If this setting conflicts with NTP-server time, the NTP time overrides the manual setting.

**Samples** `bstnA(cfg)# ntp server 192.168.25.201`  
selects an NTP server at 192.168.25.201.

`bstnA(cfg)# ntp server 192.168.25.202 version 3`  
selects another NTP server, but uses NTPv3 to communicate with it.

| <b>Guidelines</b>                        | To select this management interface for rendezvous, go to this switch's redundant peer and use the <a href="#">peer</a> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Guidelines: ARX-1500 and ARX-2500</b> | <p>As mentioned above, the ARX-1500 or ARX-2500 can also use this management interface as one end of a redundant-pair link. The redundant pair depends on this link for ongoing heartbeats and metalog updates.</p> <p>For the best failover performance in this case, we strongly recommend a gigabit or ten-gigabit connection to the redundant peer. That is, the current VLAN's channel (or member) should connect to the redundant peer and have speeds of 1-gigabit or more. We also recommend that the connection be direct (without any intervening bridges or routers), and that the switches are co-located. If the latency is low, an intervening Gigabit L2 switch is permissible.</p> <p>When <a href="#">redundancy</a> is enabled and the ARX-1500 or ARX-2500 is using this interface as a redundant-pair link, the <code>cfg-if-vlan no redundancy</code> command causes the backup peer to reboot. The reboot does not disrupt any storage services, but the ARX peers cannot function as a redundant pair while the link is shut down. Additionally, a quorum-disk failure or disconnection would cause the active peer to reboot, too. If you proceed with removing the link, you should establish a new one as soon as possible: use the <a href="#">redundancy protocol</a>, <a href="#">redundancy protocol (cfg-channel)</a>, or this command on another port, channel, or VLAN interface to establish a new redundant-pair link.</p> |
| <b>Samples</b>                           | <pre>bstnA(cfg-if-vlan[555])# redundancy</pre> <p>allows the in-band-management interface on VLAN 555 to be used for redundancy rendezvous.</p> <pre>bstnA(cfg-if-vlan[8])# no redundancy</pre> <p>disallows rendezvous for the VLAN-8 interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## show arp

**Purpose** Address-Resolution Protocol (ARP) maps IP addresses to MAC addresses. Every network-connected processor on the ARX keeps a separate ARP table with its known IP/MAC entries. Use the `show arp` command to show one or more ARP tables.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show arp [all]`  
`show arp from slot.processor [type {dynamic | static | local}]`

**all** (optional) specifies all entries on the switch.

**from slot.processor** (optional) focuses on the ARP table at one processor. This option is not supported on the ARX-1500, ARX-2500, or ARX-VE:

*slot* (1-2 for ARX-4000; 1 for all others) is the slot number.

*processor* is the processor number. Use the `show processors` command to show all processors on the ARX, along with their associated module name(s) and status.

**type {dynamic | static | local}** (optional, if you use the **from** clause) selects one type of ARP-table entry, based on how the entry was learned. You must choose one of the following:

**dynamic** - learned from neighboring equipment.

**static** - specified by the `arp` command.

**local** - set internally by the switch.

**Guidelines** Proc is the processor (in *slot.processor* format). This only appears if you use an option, **all** or **from**, on a platform other than the ARX-1500, ARX-2500, or ARX-VE.

IP Address and

MAC Address are mapped together. If the MAC address is all zeros, the ARX could not find the IP address through ARP; likely the IP address does not exist in this case.

VLAN is the VLAN where the IP address was learned or specified.

Type is

- **dynamic** if the entry was learned from neighboring equipment,
- **static** if the entry was specified by the `arp` command, or
- **local** if the entry is defined by the switch software.

The summary output (from `show arp`, without any additional arguments) shows only dynamic-ARP entries.

Age (sec) is the time the entry has been in the ARP table, shown in seconds.

Use the `arp` command to create a static ARP entry. Use the `clear arp` command to clear all dynamic-ARP entries.

**Samples** bstnA(cfg)# show arp

shows a summary of the ARP-table entries on the switch. This includes only dynamic-ARP entries. See [Figure 10.1](#) for sample output.

## bstnA(cfg)# show arp all

shows all ARP-table entries from all processors. See [Figure 10.2 on page 10-29](#) for sample output.

## bstnA(cfg)# show arp from 1.1

shows the ARP table for processor 1.1 only. See [Figure 10.3 on page 10-31](#) for sample output.

## bstnA(cfg)# show arp from 1.1 type local

shows the local ARP entries for processor 1.1. See [Figure 10.4 on page 10-32](#) for sample output.

See [Figure 10.5 on page 10-32](#) for sample output on the ARX-2000.

## show interface

**Purpose** Use the `show interface` command to show the full configuration for all interfaces. Use `show interface summary` to see a single status line for each interface.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show interface [summary]`

`summary` (optional) reduces the output to a one-line summary for each interface.

**Guidelines** The default command, `show interface`, displays all interface configurations. The output is the same for each individual show command: [show interface mgmt](#), [show interface gigabit](#), [show interface vlan](#), and [show ron](#).

The `show interface summary` command shows the following fields for each interface:

**Type** is `mgmt` (the out-of-band MGMT interface, if it exists on this chassis), `gbe` (GigaBit Ethernet, an external port), or `10gbe` (ten-Gigabit Ethernet, a faster external port on the ARX-4000).

**Slot/Port** shows the location of the interface. An asterisk (\*) indicates that the interface is used as a redundant-pair link.

**Admin State** is Enabled or Disabled (also called “shut down”), as set by the administrator. To change this, use `[no] shutdown` in the interface’s configuration mode: see [shutdown \(cfg-if-gig\)](#), [shutdown \(cfg-if-ten-gig\)](#), [shutdown \(cfg-mgmt\)](#), [shutdown \(cfg-if-vlan\)](#), or [shutdown \(cfg-if-vlan-ron-tnl\)](#). If the interface is a member of a [channel](#), its administrative state is controlled by its channel: therefore, this shows “Ch *n*,” where *n* is the channel number. You can use [show channel](#) to see the administrative state of a channel.

**Link Status** is the actual state of the interface (up or down).

**Speed and**

**Duplex** are both set by the [speed \(cfg-if-gig\)](#) command.

**Description** is set by the `description` command in the interface’s config mode: [description \(cfg-mgmt\)](#) for `fe`, [description \(cfg-if-gig\)](#) for `gbe`, or [description \(cfg-if-ten-gig\)](#) for `10gbe`.

**Samples** bstnA> **show interface**  
 shows the configuration of every interface on the current ARX. See [Figure 10.6](#) for sample output.

prt1ndA> **show interface summary**  
 shows summaries of all interfaces on the “prt1ndA” chassis. For sample output, see [Figure 10.7 on page 10-40](#).

canbyA> **show interface summary**  
 shows summaries of all interfaces on the “canbyA” chassis, an ARX-1500. For sample output, see [Figure 10.8 on page 10-41](#).

**Related Commands** [show interface gigabit](#)

## show interface mgmt

- Purpose** Administrators can log into the CLI or GUI through the out-of-band management interface, typically labeled “MGMT.” Use the `show interface mgmt` command to show the configuration and status of the out-of-band management interface.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show interface mgmt [stats]`
- stats** (optional) displays statistics for the interface.
- Platforms** any *except* ARX-VE
- Guidelines** The default output contains the following fields:
- Slot is always “1,” and
  - Interface is also always “1.” The 1/1 interface is the MGMT interface for all platforms.
  - Description is an optional description, set by the [description \(cfg-mgmt\)](#) command.
  - Admin Status shows whether or not the interface is administratively enabled. You can disable (or restart) this interface with the [shutdown \(cfg-mgmt\)](#) command.
  - Link Status is the actual state of the interface (up or down).
  - Speed,
  - Duplex, and
  - Auto Negotiation are all set by the [speed \(cfg-mgmt\)](#) command.
  - MAC Address is the MAC for the MGMT interface.
  - MTU Size shows the Maximum Transmission Unit, or maximum packet size, for this interface.
  - IP Address, and
  - Subnet Mask define the management address and subnet. You can set these with the [ip address \(cfg-mgmt\)](#) command.
- The **stats** output is a table of counters, separated into Ingress and Egress counts. These counts restart when the ARX reboots; use the [reload](#) command to reboot the ARX. On an ARX-1500 or an ARX-2500, you can use the [clear counters mgmt](#) command to clear the stats, without performing a full reboot.
- Use the [show interface vlan](#) command to list all of the VLAN-based in-band management interfaces.

**Samples** bstnA# `show interface mgmt`  
 shows the configuration and status of the out-of-band management interface. See [Figure 10.9](#) for sample output.

bstnA# `show interface mgmt stats`  
 shows the statistics for the same interface. Sample output appears in [Figure 10.10](#).

**Related Commands** [description \(cfg-mgmt\)](#)  
[ip address \(cfg-mgmt\)](#)  
[speed \(cfg-mgmt\)](#)  
[shutdown \(cfg-mgmt\)](#)  
[show interface vlan](#)  
[clear counters mgmt](#)

```

## show interface vlan

- Purpose** You can configure one in-band-management interface per VLAN. Administrators on the VLAN can log into the CLI through this interface. Use the `show interface vlan` command to show the configuration for all in-band management interfaces.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show interface vlan`
- Guidelines** Vlan is the VLAN ID for the interface.  
Admin shows whether or not the interface is administratively enabled. You can disable (or restart) an in-band-management interface with the `shutdown (cfg-if-vlan)` command.  
IP Address, and  
Subnet Mask define the management address and subnet. You can set these with the `ip address (cfg-if-vlan)` command.  
Description is an optional description, set by the `description (cfg-if-vlan)` command.  
Use the `show interface mgmt` command to show the configuration for the single out-of-band management interface.
- Samples** `bstnA(cfg)# show interface vlan`  
shows a summary of configured VLANs. See the sample output below.
- Related Commands** `description (cfg-if-vlan)`  
`ip address (cfg-if-vlan)`  
`shutdown (cfg-if-vlan)`

*Figure 10.11 Sample Output: show interface vlan*

```
bstnA(cfg)# show interface vlan
```

| Vlan | Admin   | IP Address   | Subnet Mask   | Description |
|------|---------|--------------|---------------|-------------|
| 25   | Enabled | 192.168.25.5 | 255.255.255.0 |             |

---

# show ip address

**Purpose** Use the `show ip address` command to show configuration details for a Proxy IP, private IP, VIP, or some other IP address on the ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ip address ip-address`

*ip-address* is the desired IP address (for example, 192.168.25.56).

**Guidelines** Slot ID shows the location of the module that processes all packets for the address. Processor is the network processor that serves the address. Every IP address is assigned to a single network processor. Use the `show processors` command to show all processors.

Type is any of the following:

- **External** is an IP address not owned by the switch, for example, the IP address of a router or a back-end filer.
- **Proxy** is a proxy-IP address. Use the `show ip proxy-addresses` command to show all proxy IPs.
- **VIP** is a virtual-IP address. Use the `show virtual service` command to show all Virtual IPs.
- **management** is the out-of-band-management interface. Use the `show interface mgmt` command to show this interface.
- **VLAN** is an in-band (VLAN-based) management interface. Use the `show interface vlan` command to list these interfaces.

MAC Address is the MAC for the IP.

VLAN ID is the VLAN for IP's subnet.

**Sample** `prt1ndA(cfg)# show ip address 192.168.74.91`

```
Report for 0.0.0.0
Slot ID :1
Processor :2
Type :VIP
MAC Address:00:0a:49:17:b1:c0
VLAN ID :74
```

**Related Commands** [show processors](#)  
[show ip proxy-addresses](#)  
[show virtual service](#)  
[show interface mgmt](#)  
[show interface vlan](#)

## show ip domain

**Purpose** The ARX can perform DNS lookups to translate IP addresses (for example, “172.16.36.55”) into FQDNs (for example, “www.mycompany.com”). Use the `show ip domain` command to show the current configuration for DNS lookups.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ip domain`

**Guidelines** Domain List is analogous to the *search* list in *resolv.conf*. To edit this, use the [ip domain-list](#) command.  
Name Servers is analogous to the *nameserver* list in *resolv.conf*. To edit this, use the [ip name-server](#) command.

**Sample** `bstnA(cfg)# show ip domain`

```
DNS Server Configuration
Domain List: wwmed.com medarch.org bigorg.org
Name Servers: 192.168.25.201 192.168.25.202 192.168.25.209
shows the current configuration for DNS lookups.
```

**Related Commands** [ip domain-list](#)  
[ip name-server](#)

# show ip proxy-addresses

**Purpose** Every network processor on the ARX has a *proxy IP* address, used as a home address for communication with filers and servers on the back end. Use the `show ip proxy-addresses` command to show all configured proxy IPs.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ip proxy-addresses`

**Guidelines** This command displays a table of proxy IP addresses, one per row. For a redundant pair of switches, this shows all proxy IPs for both peers.

**Proxy Address** is the IP address.

**VLAN** is the VLAN where the proxy IP resides.

**MAC Address** is the layer-2-MAC address for the proxy IP.

**Owner** is the chassis where the proxy IP was configured. This is relevant in a redundant-switch configuration.

**In Use By** is the chassis that is currently using the proxy IP. In a redundancy failover, the surviving chassis assumes all proxy IPs from the failed chassis.

**Proc** identifies the network processor that is using the proxy IP, in *slot.processor* format.

Use the `ip proxy-address` command to add a range of proxy-IP addresses.

**Samples** `bstnA# show ip proxy-addresses`

See [Figure 10.12 on page 10-47](#) for sample output from a non-redundant peer.

`prt1ndA# show ip proxy-addresses`

See [Figure 10.12 on page 10-47](#) for sample output from a redundant peer.

**Related Commands** [ip proxy-address](#)  
[show processors](#)

*Figure 10.12 Sample Output: show ip proxy-addresses*

# show ip route

**Purpose** Use the `show ip route` command to show the active and static routes on the switch.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ip route [all | from slot.processor | monitor]`

**all** (optional) specifies all routes on the switch.

**from *slot.processor*** (optional) specifies routes from one network processor. This option is not supported on the ARX-1500, ARX-2500, or ARX-VE:

***slot*** (1-2 on an ARX-4000, 1 on any other platform) is the slot number, and

***processor*** is the processor number. Use the [show processors](#) command to show a complete list of processors.

**monitor** (optional) shows the status of the next-hop gateway, and how the ARX is using it.

**Guidelines** Every network processor on the ARX has its own IP-routing table. (In addition to the processors behind the client/server Ethernet ports, this includes processor 1.1 because it connects to the out-of-band network.) The `show ip route all` command shows the routing tables for all processors. Many routes are common to all processors; duplicate routes are removed from the summary command, `show ip route`.

Use the [ip route](#) command to create a static route.

All versions of this command except `show ip route monitor` have the following fields:

**Proc** is the number of the module processor with the static route, in *slot.processor* format. This only appears if you use an option, **all** or **from**, on a platform other than the ARX-1500, ARX-2500, or ARX-VE. Each processor has a separate routing table. Use the [show processors](#) command to show a complete list of processors and their slots.

**Destination/Mask** defines the subnet for a route in CIDR format.

**Gateway** is the next-hop router for the route.

**Cost** is the relative cost of this route, weighed against any other routes to the same destination. A lower-cost metric is preferred.

**Interface** is the interface or VLAN that carries packets to this subnet. “Mgmt” is the out-of-band management interface, labeled MGMT on the front panel.

**Age** is the time (in seconds) that the ARX has been in continuous contact with the Gateway. The ARX uses periodic ARP requests to monitor the gateway while the route is active; the route is declared “Offline” if it fails to respond to ARPs. “Direct” means that the route is directly-connected to the interface. “Unacquired” applies to a per-VLAN-default route (created with `ip route ... per-vlan`), where the gateway has not yet responded to ARP requests. “Static” means that the per-VLAN route has responded to an ARP request and is evidently reachable.

**Guidelines: show ip  
route monitor**

The `show ip route monitor` command has similar output to `show ip route`, but it focuses on the status of the connections. It contains the following fields:

**Destination/Mask** defines the subnet for a route in CIDR format.

**Type** is the general destination for the route. This is either “VLAN” (indicating a client/server VLAN) or “Mgmt” (the out-of-band management subnet). “Mgmt” routes are created with a special flag in the `ip route` command.

**Gateway** is the next-hop router for the route.

**Cost** is the relative cost of this route, weighed against any other routes to the same destination. A lower-cost metric is preferred.

**Status and**

**Details** indicate whether or not this route is in use. If it is, this indicates how the switch uses the next-hop gateway. If not, it indicates the problem. Here are the possible conditions in this field:

- **Up/Current Gateway** indicates that the switch uses this route (as opposed to another static route to the same subnet).
- **VLAN/Current Gateway** applies to a per-VLAN-default route, created with the `ip route ... per-vlan` variant of the `ip route` command. This indicates that VLAN-default route is configured.
- **Up/Backup Gateway** is a gateway that is available to reach the subnet, but is not being used because some other, preferred gateway is being used instead. Another route should be in the same output with the same **Destination/Mask**, a different **Gateway**, and **Status/Details** of **Up/Current Gateway**. If this subnet’s **Current Gateway** stops responding to ARP packets, this route is a candidate to take its place.
- **Down/No Reply** shows that the gateway is reachable through layer 2 and ICMP, but is not replying to IP packets.
- **Down/Unreachable** says that the gateway is not on a reachable subnet. Use `ip route` to reset the gateway. A gateway to file servers must be on the same subnet as the proxy-IP addresses (`show ip proxy-addresses` shows all such addresses), a gateway to clients must be on the same subnet as the clients’ VIP (use `show virtual service` for a list of all VIPs), and a gateway to stations in the out-of-band (OOB) management network must be in the same subnet as the OOB management address (`show interface mgmt`).

**Samples** bstnA> show ip route

lists the static routes on the switch by IP address. See [Figure 10.14 on page 10-51](#) for sample output. For sample output on a different platform, see [Figure 10.18 on page 10-53](#).

## bstnA&gt; show ip route monitor

displays the current status of all of the above routes. See [Figure 10.15 on page 10-51](#) for sample output. For sample output on a different platform, see [Figure 10.19 on page 10-53](#).

## bstnA&gt; show ip route all

shows all static routes for all processors on the switch. See [Figure 10.16 on page 10-51](#) for sample output. For sample output on a different platform, see [Figure 10.20 on page 10-53](#).

## bstnA&gt; show ip route from 2.1

shows the static routes from processor 1 on module 2 (the NSM, or Data Plane). See [Figure 10.17 on page 10-53](#) for sample output. For sample output on a different platform, see [Figure 10.21 on page 10-54](#).

## show ntp servers

**Purpose** Use the `show ntp servers` command to display all configured NTP servers.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ntp servers`

**Guidelines** This command displays a table of NTP servers. For each server, the table shows a numeric ID, the NTP protocol for the server (3 for NTPv3 or 4 for SNTPv4), the number of seconds between Polls, and the server's IP address.

Use the [ntp server](#) command to add an NTP server to the list. Use the [show clock](#) command to verify that the switch is getting the correct time from the NTP server(s).

**Related Commands** [ntp server](#)  
[show clock](#)

*Figure 10.22 Sample Output: show ntp servers*

```
bstnA(cfg)# show ntp servers
```

```
Configured NTP Servers
```

| ID | Proto | Poll | Address        |
|----|-------|------|----------------|
| 2  | 4     | 64   | 192.168.25.201 |
| 1  | 4     | 64   | 192.168.25.209 |

## show ntp status

**Purpose** Use the `show ntp status` command to display operational status for each configured NTP server.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ntp status`

**Guidelines** This command displays operational status information for each configured NTP server, one row per server. The fields match the output of the `pe[er]` command on the Unix `ntpq` program, or `ntpq -p` on Windows:

(tally code) - the one-character tally code, representing the server's current status (see [Table 10.1, "Tally Codes," on page 57](#)),

remote - the remote NTP server's hostname or IP address,

refid - the IP address or hostname of the server's reference clock (another NTP server; 0.0.0.0 if unknown),

st - the stratum of the server (1-16, where 1 is ideal, 15 is worst, and 16 means "unusable"),

t - the type of the NTP server (local, unicast, multicast, or broadcast) when the last packet was received,

when - the time of the last received packet,

poll - the number of seconds between polls,

reach - the reachability register, in octal,

delay - the interval (in milliseconds) to be added to requests that require authentication,

offset - the number of milliseconds between the server's clock and the ARX clock, and

jitter - the estimated time error of the server clock, measured as an exponential average of RMS time differences.

Use the [show ntp servers](#) command to get a list of all configured NTP servers. Use the [show clock](#) command to verify that the switch is getting the correct time from the NTP server(s).

**Related Commands** [show ntp servers](#)  
[show clock](#)

|                      |                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>*</b>             | sys.peer - The local switch has declared the peer the “system peer;” the peer lends its variables to the system variables.                                                                                                                                                                |
| <b>o</b>             | pps.peer - The peer has been declared the system peer and lends its variables to the system variables. However, the actual system synchronization is derived from a pulse-per-second (PPS) signal, either indirectly via the PPS reference clock driver or directly via kernel interface. |
| <b>+</b>             | candidate - The peer is a survivor and a candidate for the combining algorithm.                                                                                                                                                                                                           |
| <b>#</b>             | selected - The peer is a survivor, but not among the first six peers sorted by synchronization distance. If the association is ephemeral, it may be demobilized to conserve resources.                                                                                                    |
| <b>.</b>             | excess - The peer is discarded as not among the first ten peers sorted by synchronization distance. It is probably a poor candidate for further consideration.                                                                                                                            |
| <b>&lt;Space&gt;</b> | reject - The peer is discarded as unreachable, synchronized to this server (synch loop) or excessive synchronization distance.                                                                                                                                                            |
| <b>x</b>             | falsesticker - The peer is discarded by the intersection algorithm as a falsesticker.                                                                                                                                                                                                     |
| <b>-</b>             | outlyer - The clustering algorithm designated the peer as an outlyer and discarded it.                                                                                                                                                                                                    |

## shutdown (cfg-if-vlan)

**Purpose** From `cfg-if-vlan` mode, use the `shutdown` command to shut down the in-band management interface for a VLAN.

### ◆ Important

*In a redundant pair of ARXes, the network software uses an in-band (VLAN) management address as a home address for its communication with the [quorum-disk](#). Without an in-band-management address and an [ip route](#) to the quorum disk, a failover is impossible. If this interface has [redundancy \(cfg-if-vlan\)](#) enabled, the `shutdown` command causes the backup to reboot. Additionally, any [ron tunnels](#) that use this address will fail if you shut it down; a [shadow-copy-rule](#) depends on RON tunnels to communicate with other ARXes in the network.*

*Use the `shutdown` command only on the advice of F5 Support.*

Use `no shutdown` to restart the management interface.

**Mode** `cfg-if-vlan`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `shutdown`  
`no shutdown`

**Default(s)** `shutdown`

**Guidelines** If you shut down the in-band management interface, administrators are immediately disconnected from the interface.

An ARX in a redundant pair has additional issues. A redundant ARX requires an in-band (VLAN) management interface on the same VLAN as its quorum disk. This is required so that the ARX can reach its quorum disk while in the backup role. Refer to the [quorum-disk](#) documentation for more details. If this interface has [redundancy \(cfg-if-vlan\)](#) enabled, the interface is even more vital to redundancy; in this case, a `shutdown` causes the backup ARX to reboot. Do not shut down this interface if this ARX has a quorum disk on the current VLAN or if the interface is used as the redundancy link.

If the current in-band (VLAN) interface terminates any Resilient Overlay Network (RON) tunnels, this command shuts down communication with all of them. This could potentially disrupt a shadow-copy rule or management access to another ARX.

**Samples** `bstnA(cfg-if-vlan[4])# shutdown`  
shuts down the in-band management interface for VLAN 4.

`bstnA(cfg-if-vlan[4])# no shutdown`  
restarts the same interface.

**Related Commands** [interface vlan](#)  
[quorum-disk](#)  
[ron tunnel](#)

## shutdown (cfg-mgmt)

|                         |                                                                                                                                                                                                                                                                                                                                                                                                 |

## speed (cfg-mgmt)

**Purpose** From `cfg-mgmt` mode, use the `speed` command to set the speed and duplex configuration on the fast Ethernet port for the switch's out-of-band (OOB) management interface.

**Mode** `cfg-mgmt`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `speed {auto | 100-half | 100-full | 10-half | 10-full | 1000-full}`

`auto | 100-half | 100-full | 10-half | 10-full | 1000-full` is a required choice:

`auto` is auto-negotiate (the default) 10/100 megabits-per-second (mbps), half/full duplex. Makes the port auto-negotiate with its peer. Use this setting to enable MDI/MDIX cross-over on the OOB-management port.

`100-half` is fast Ethernet, 100 mbps, half duplex.

`100-full` is fast Ethernet, 100 mbps, full duplex.

`10-half` is fast Ethernet, 10 mbps, half duplex.

`10-full` is fast Ethernet, 10 mbps, full duplex.

`1000-full` is Gigabit Ethernet, 1000 mbps, full duplex.

**Default(s)** `auto`

**Platforms** any *except* ARX-VE

**Guidelines** The ARX has one out-of-band management interface labeled MGMT on the front panel of the switch.

The MGMT port supports automatic MDI/MDIX cross-over. This feature automatically corrects the polarity of the attached CAT5 cable, regardless if it is a cross-over or straight-through type. However, the port must be set to "auto" (auto-negotiate enabled). When the port speed/duplex is forced, automatic MDI/MDIX cross-over is disabled, and you must cable the port using standard cross-over or straight-through cabling. That is, connections between switches and/or routers require a "crossover" cable, and connections between switches/routers to hosts/end-stations require a "straight-through" cable.

**Sample** `bstnA(cfg)# interface mgmt`  
`bstnA(cfg-mgmt)# speed 100-half`

For the OOB-management interface, sets the fast Ethernet port speed to 100 mbps and the duplex configuration to half duplex.

## wait-for ip-routes

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>wait-for ip-routes</code> command to wait until all of your configured static routes are operational.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Mode</b>             | (any)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Security Role(s)</b> | network-technician, network-engineer, storage-engineer, or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Syntax</b>           | <code>wait-for ip-routes [timeout <i>timeout</i>]</code><br><br><i>timeout</i> (optional, 1-2096) is the timeout value in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default(s)</b>       | <i>timeout</i> - none, wait indefinitely                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Guidelines</b>       | <p>This command is useful in CLI scripts.</p> <p>After you have established one or more static routes with the <code>ip route</code> command, you can use the <code>wait-for ip-routes</code> command to wait for all of those routes to come online. This can be useful for CLI scripts, which you can copy onto the switch (with <code>copy ftp</code>, <code>copy scp</code>, <code>copy {nfs cifs}</code>, or <code>copy tftp</code>), and <code>run</code>.</p> <p>If you set a <i>timeout</i> and it expires before the last static route is up, the command exits with a warning. To interrupt the <code>wait-for ip-routes</code> command, press <code>&lt;Ctrl-C&gt;</code>. You can use the <code>show ip route monitor</code> command to see the current status of all static routes.</p> |
| <b>Samples</b>          | <pre>stkbrgA# wait-for ip-routes</pre> <p>waits indefinitely for all static routes to come up. The CLI prompt does not return until this command proves that all routes are functional.</p> <pre>stkbrgA# wait-for ip-routes timeout 30</pre> <p>waits up to 30 seconds for all static routes to come up.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Related Commands</b> | <code>ip route</code><br><code>show ip route</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## license activate

**Purpose** Use the `license activate` command to activate your software license and begin setting up storage services on the ARX.

**Mode** `priv-exec`

**Security Role(s)** `crypto-officer`

**Syntax** `license activate base-reg-key base-key`  
`license activate add-on-key add-key`

**base-reg-key *base-key*** (1-33 characters) is the base registration key for the current ARX. If you purchased hardware with Release 6.00.000 or later, the key is installed before shipment; use the `<tab>` key to auto-complete your base registration key. To upgrade older hardware to Release 6.00.000 or later, contact your F5 Sales representative to purchase a license and receive the key in an E-mail message. For trial software, you can get a key for a trial license E-mailed to you from the same site where you downloaded the software, <https://www.f5.com/trial/>.

**add-on-key *add-key*** (1-15 characters) is a registration key for an add-on license. You can purchase an add-on license to add more capacity or additional features to your ARX. As above, contact your F5 Sales representative to purchase an add-on license and receive the key in an E-mail message.

**Guidelines: Trial or Evaluation Licenses in a Redundant Pair**

Trial licenses, obtained from <https://www.f5.com/trial/>, and evaluation licenses have an expiration date built into them. The timer for the license expiration begins when you run the `license activate` command or manual activation (described below). If you are installing one of these temporary licenses on a redundant pair of ARX devices, the start dates should be no more than 24 hours apart. We recommend activating the license at both peers on the same day. This avoids a large gap in time where one peer is licensed and the other peer is unlicensed, and it also avoids an SNMP trap that warns you of the license mismatch.

**Guidelines: Automatic Activation**

This command contacts a license server at F5, <http://activate.f5.com/>, so the ARX must have a static route (`ip route`) to the Internet and access to a DNS server (`ip name-server`) before you use it. These network settings should be properly configured during installation, in the initial-boot script. You can use `ping license-server` to confirm that you have a usable connection to the server. If not, you can use the `show ip route` command for a list of static routes, and use `show ip route monitor` to check the status of each route. You can also use `show ip domain` to see your DNS setup, and/or `ip name-server` to add a new DNS server to the ARX configuration.

If circumstances or network policy prevents you from connecting the ARX to the Internet, you can use a manual activation method, as described in the documentation for the `license create license-dossier` command.

In a redundant pair of switches, each ARX has its own license. Activate the license on both peers. If there are any add-on licenses, activate those on both peers, too.

**Guidelines: Automatic Activation (Cont.)**

Your initial license activation requires contact information and acceptance of an End-User License Agreement (EULA). The CLI only requests this information if you have not already entered it through other means.

The contact information comes in two parts: general information and an E-mail address.

The CLI requests general information first, with prompts for the following items:

- First Name
- Last Name
- Company Name
- Phone
- Job Title
- Address
- City
- State/Province
- Postal Code
- Country

Then the CLI shows you a summary of these items; enter **yes** to accept the entries, or **no** to restart the list.

The CLI then prompts you for an E-mail address. If you see this, enter the E-mail address and then re-enter it as prompted.

The End-User License Agreement (EULA) appears next and prompts you for confirmation. The EULA also appears for a re-run of this command if the agreement text has changed in any way. If the EULA appears, review the agreement carefully and then enter **yes** to accept it.

An information message appears at the end indicating the final success or failure of your license activation.

Use the [show active-license](#) command to see all of the licensed limits after you install the base license.

An add-on license changes the limits expressed in [show active-license](#); the CLI informs you of all the changes after you run this command with the **add-on-key** option.

**Sample**

```
stkbrgA# license activate base-reg-key CRJGV-QPDYW-SATNK-RGBYY-DMTMOBL
% INFO: The license has been successfully activated.
```

automatically activates the license for the “stkbrgA” switch.

[clear active-license](#)

## license activate file

**Purpose** Some installations do not permit a network connection from the ARX to the Internet, but an Internet connection is required to access a valid F5 license server. For these installations, a manual process is necessary to activate the license on the ARX. The manual-activation process involves downloading a valid license file from the F5 license server to a remote host, and then transferring the license file to the ARX. The final step in manual-license activation is activating that valid license file on the ARX. Use the `license activate file` command to activate a valid license file, one that was downloaded from <http://activate.f5.com/>. You can also use it to activate a copy of the “active.license” file (which is created by the `license activate` command).

**Mode** priv-exec

**Security Role(s)** crypto-officer

**Syntax** `license activate file file-name`

*file-name* (1-1024 characters) is the name of the license file to activate. For a full list of available license files, you can use the `show license` command.

**Guidelines** You can use a faster method for activating your license if the ARX has a valid route to the license server at <http://activate.f5.com/>. The `ping license-server` command tests the connection between the ARX and the license server. If this ping command succeeds, you can use the `license activate` command instead of this one.

**Guidelines: Manual Activation** The manual activation process starts at the ARX CLI, continues on a remote host with access to the F5 server, and then concludes at the ARX CLI:

- The `license create license-dossier` command creates a dossier file to identify the ARX and enumerate its capabilities. The file name is “arx.dossier;” you can use the `show license-dossier` command to confirm that it exists.
- Use your preferred form of the `copy` command (such as `copy ftp`, `copy scp`, or `copy smtp`) to upload the arx.dossier file to a host that can connect to the Internet. For sites where such an upload is not permitted, you can use an alternative that is described below.
- From an HTTP browser on the remote host, connect to the following site and fill out the forms for getting an ARX license:  
<http://activate.f5.com/>  
When prompted to enter the ARX dossier, you can either upload it from the location above, or you can copy and paste the encrypted output from `show license-dossier`.  
This creates a file with a “.license” extension (such as “arx.license”) on the remote host.
- At the ARX CLI, use `copy source-url license arx.license` to download the “.license” file from the remote host to the “license” directory on the ARX.
- Use this command, `license activate file arx.license`, to activate this new license on the ARX. One or more information messages appear at the end indicating the final success or failure of your license activation.

---

**Guidelines: Trial or Evaluation Licenses in a Redundant Pair**

Trial licenses, obtained from <https://www.f5.com/trial/>, and evaluation licenses have an expiration date built into them. The timer for the license expiration begins when you run the `license activate` command or this command. If you are installing one of these temporary licenses on a redundant pair of ARX devices, the start dates should be no more than 24 hours apart. We recommend activating the license at both peers on the same day. This avoids a large gap in time where one peer is licensed and the other peer is unlicensed, and it also avoids an SNMP trap that warns you of the license mismatch.

**Sample**

```
stkbrgA# license activate file arx.license
% INFO: The license has been successfully activated.
activates the license in the "arx.license" file.
```

**Related Commands**

- `show license`
- `license activate`
- `license create license-dossier`
- `copy ftp`
- `copy {nfs|cifs}`
- `copy scp`
- `copy smtp`
- `show license-dossier`
- `clear active-license`

## license create license-dossier

**Purpose** Some installations do not permit a network connection from the ARX to the Internet, but an Internet connection is required to access a valid F5 license server. For these installations, a manual process is necessary to activate a license on the ARX. The first step in manual-license activation is creating a *dossier* file that describes the current ARX. Use the `license create license-dossier` command to create the dossier file.

**Mode** `priv-exec`

**Security Role(s)** `crypto-officer`

**Syntax** `license create license-dossier base-reg-key base-key`  
`license create license-dossier add-on-key add-key`

**base-reg-key base-key** (1-33 characters) is the base registration key for the current ARX. If you purchased hardware with Release 6.00.000 or later, the key is installed before shipment; use the `<tab>` key to auto-complete your base registration key. To upgrade older hardware to Release 6.00.000 or later, contact your F5 Sales representative to purchase a license and receive the key in an E-mail message. For trial software, you can get a key for a trial license E-mailed to you from the same site where you downloaded the software, <https://www.f5.com/trial/>.

**add-on-key add-key** (1-15 characters) is a registration key for an add-on license. You can purchase an add-on license to add more capacity or additional features to your ARX. As above, contact your F5 Sales representative to purchase an add-on license and receive the key in an E-mail message.

**Guidelines** You can use a faster method for activating your license if the ARX has a valid route to the license server at <http://activate.f5.com/>. The `ping license-server` command tests the connection between the ARX and the license server. If this ping command succeeds, you can use the `license activate` command instead of this one.

**Guidelines: Manual Activation** This command creates a dossier file to identify the ARX and enumerate its capabilities. The file name is “`arx.dossier`,” you can use the `show license-dossier` command to confirm that it exists.

Then use your preferred form of the `copy` command (such as `copy ftp`, `copy scp`, or `copy smtp`) to upload the `arx.dossier` file to a host that can connect to the Internet.

For sites where such an upload is not permitted, you can use an alternative that is described below.

From an HTTP browser on the remote host, connect to the following site and fill out the forms for getting an ARX license:

<http://activate.f5.com/>

When prompted to enter the ARX dossier, you can either upload it from the location above, or you can copy and paste the encrypted output from `show license-dossier`.

This creates a file with a “.license” extension (such as “`arx.license`”) on the remote host.

At the ARX CLI, use `copy source-url license arx.license` to download the “.license” file from the remote host to the “license” directory on the ARX.

Use `license activate file arx.license` to activate this new license on the ARX.

**Sample**

```
stkbrgA# license create license-dossier base-reg-key CRJGV-QPDYW-SATNK-RGBYY-DMTMOBL
```

creates a dossier file, "arx.dossier," for the "stkbrgA" switch.

- [copy smtp](#)
- [show license-dossier](#)
- [license activate file](#)
- [clear active-license](#)

## ping license-server

**Purpose** Use the `ping license-server` command to send a simple request to your license server. This verifies that you can connect to the license server and use the automatic `license activate` command.

**Mode** (any)

**Security Role(s)** crypto-officer

**Syntax** `ping license-server [base-reg-key base-key]`

**base-reg-key *base-key*** (1-33 characters) is the base registration key for the current ARX. If you purchased hardware with Release 6.00.000 or later, the key is installed before shipment; use the <tab> key to auto-complete your base registration key. To upgrade older hardware to Release 6.00.000 or later, contact your F5 Sales representative to purchase a license and receive the key in an E-mail message. For trial software, you can get a key for a trial license E-mailed to you from the same site where you downloaded the software, <https://www.f5.com/trial/>. This option is unnecessary after activation.

**Guidelines** The output from a successful ping shows the current time at the F5 license server, <http://activate.f5.com/>.

If the output shows an error instead of a timestamp, the license server is unreachable. The ARX must have a static route (`ip route`) to the Internet for this command to succeed. Use the `show ip route` command for a list of static routes, and use `show ip route monitor` to check the status of each route.

The ARX must also have a DNS server available for translating server FQDNs into IP addresses; use `show ip domain` to see your DNS setup, and/or `ip name-server` to add a new DNS server to the ARX configuration.

If circumstances or network policy prevents you from connecting the ARX to the Internet, you can use a manual activation method, as described in the documentation for the `license create license-dossier` command.

**Sample** `stkbrgA# ping license-server`

```
% INFO: Activation server response: 'Tue Nov 09 14:52:01 UTC 2010'
```

indicates that you can reach the license server, and that you can therefore use `license activate` to automatically activate your software license.

**Related Commands** `license activate`  
`ip route`  
`show ip route`  
`ip name-server`  
`ip domain-list`  
`show ip domain`

---

# show active-license

**Purpose** Use the `show active license` command to display a complete list of all features and limits that are currently licensed on this ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show active-license`

**Guidelines** This command shows a list of all currently-licensed options. This information is broken into several tables.

System License Information is information about the active license itself. Here are some key fields in the output:

**Auth Vers.** is for internal use only.

**Usage** indicates the intended usage for the license. This is also for internal use only.

**Registration Key** is the base registration key used for `license activate` and similar commands.

**Licensed version** identifies the software release that is licensed. This is a release number with an `x.y.0` format. You are permitted to install any maintenance release off of the same base, such as `x.y.1`, `x.y.2`, and so on.

**License Date** is the date when the license was first activated with `license activate`, `license activate file`, or a GUI equivalent.

**License Start** is the earliest date when the license could be valid. This does not appear for a production license, which has no start or end date.

**License End** is the expiration date for the license. This field also does not appear for a production license.

**Service Check Date** is used for comparison to any software that is installed later. The date of a major release is included in its release file; if that date is earlier than the license's *service-check date* (in this field), you are permitted to install the new release. Use the `show releases` command to get a list of all release files on the ARX, and use `boot system` to prepare the ARX to install the new release.

**Platform ID** identifies the ARX platform to which this license applies. The codes are Z100 for an ARX-VE, A106 for an ARX-500, D108 for an ARX-2000, D103 for an ARX-4000, C110 for an ARX-1500, or C111 for an ARX-2500.

**Service Status** is a string to explain the implications of the **Service Check Date** above.

**Module List** contains a sub table for each add-on license. Add-on licenses will be supported in a future release.

**Feature List** shows all of the features and limits that the active license supports.

Some of these features contain a suffix of “\_4k.” This indicates that the values are shown in blocks of 4,096. Multiply each such value by 4096 to get the actual limit.

**Guidelines (Cont.)** Use the `license activate` command to automatically activate the license for the current ARX. Automatic activation is only possible if the ARX has a network connection to the F5 web site, <http://activate.f5.com/>; if not, you can use the `license create license-dossier` command to start the process of manual activation.

**Sample** `bstnA# show active-license`  
shows the active license and all the options that it enables. See [Figure 11.1 on page 11-12](#) for sample output.

**Related Commands** `license activate`  
`license create license-dossier`

## show license-dossier

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | A license <i>dossier</i> is a file that describes the ARX and its capabilities. The dossier file is used for license activation; the license server requires the ARX dossier to provide you with a license. The dossier is encrypted. When you activate your license manually, you can copy and paste the encrypted dossier into the form on <a href="http://activate.f5.com/">http://activate.f5.com/</a> . Use the <code>show license-dossier</code> command to display the dossier file as an encrypted string.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Mode</b>             | (any)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Syntax</b>           | <code>show license-dossier</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Guidelines</b>       | <p>This command is only useful for a manual license activation. You can use a faster method for activating your license if the ARX has a valid route to the Internet. If the ARX can connect to the Internet, you can use the <code>license activate</code> command to automatically activate your license.</p> <p>This command shows the encrypted string that represents your dossier file, if the file exists. You can copy this string from the CLI and paste it into the proper field at <a href="http://activate.f5.com/">http://activate.f5.com/</a>. As an alternative, you can use some form of the <code>copy</code> command (such as <code>copy ftp</code>, <code>copy scp</code>, or <code>copy smtp</code>) to copy the “arx.dossier” file to another host, and upload the dossier from that host to <a href="http://activate.f5.com/">http://activate.f5.com/</a>.</p> |
| <b>Sample</b>           | <pre>stkbrgA# show license-dossier</pre> <p>shows the “arx.dossier” file in encrypted form. See <a href="#">Figure 11.2 on page 11-14</a> for sample output.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Related Commands</b> | <a href="#">license activate</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# show snmp-server

**Purpose** Use the `show snmp-server` command to see all SNMP-configuration settings.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show snmp-server`

**Guidelines** System Information contains configuration information:

- Name can be reset with the [snmp-server name](#) command.
- Contact can be set with [snmp-server contact](#).
- Location can be changed with [snmp-server location](#). Name, Contact, and Location are the configurable parts of the MIB-2 system table.
- Interface is the interface used for SNMP communication: this is either “Management,” “VLAN,” or “None,” as set by the `cfg-mgmt-access permit` command.
- Traps shows the scope of SNMP traps that the ARX can send. The options are “Private Traps enabled” (the traps that are unique to the ARX, cataloged in the [ARX SNMP Reference](#)), “All Traps enabled” (ARX-only traps together with generic SNMP traps), or “Disabled.” You can set this with the [snmp-server traps](#) command.

Access Mode/Communities is a table of access permissions (read-only, or read-write) and the community string associated with each. The community string is encrypted. You can use [snmp-server community](#) to set it.

Trap Targets shows all of the SNMP hosts configured to receive traps. Use [snmp-server host](#) to change this list.

Trusted Hosts are allowed to perform gets and/or sets. The [snmp-server trusthost](#) command controls this setting.

**Sample** `bstnA> show snmp-server`

shows the SNMP configuration for the “bstnA” switch. See [Figure 12.1](#) for sample output.

**Related Commands** [snmp-server contact](#)

## snmp-server community

|                         |                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | External SNMP agents use a community string to access the local SNMP agent. Use the <code>snmp-server community</code> command to enter a valid community string for SNMP access.<br><br>Use the <code>no</code> form of <code>snmp-server community</code> to remove a community string from the list.                                                                                   |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>           | <code>snmp-server community <i>community-string</i> {read-only   read-write}</code><br><code>no snmp-server community <i>community-string</i> {read-only   read-write}</code><br><br><i>community-string</i> is up to 16 characters.<br><br><code>read-only</code>   <code>read-write</code> is a required choice. This sets the permissions for agents that access the local SNMP agent. |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Guidelines</b>       | You can use this command multiple times, once for each supported community string. The <code>no</code> form removes one of the strings from the list.<br><br>After you have configured a community string with this command, you can use the <a href="#">snmp-server trusthost</a> command for each trusted SNMP host.                                                                    |
| <b>Samples</b>          | <code>bstnA(cfg)# snmp-server community public read-only</code><br>establishes read-only access for trusted hosts that use the “public” community string in their SNMP queries.<br><br><code>bstnA(cfg)# no snmp-server community experimental read-write</code><br>removes a community string, “experimental,” from the list of valid strings.                                           |
| <b>Related Commands</b> | <a href="#">snmp-server trusthost</a>                                                                                                                                                                                                                                                                                                                                                     |

## snmp-server contact

**Purpose** Use the `snmp-server contact` command to enter contact information (sysContact, MIB-2.1.1.4) for the ARX.

Use no `snmp-server contact` to clear the contact information.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `snmp-server contact contact-info`  
`no snmp-server contact`

*contact-info* (1-255 characters) is the SNMP contact information. Use quotation marks around the string if it contains any spaces.

**Default(s)** No contact information is set.

**Guidelines** The sysContact MIB object is part of the MIB-2.system tree, MIB-2.1.1.4. Use the [hostname](#) command to set the sysName object, and use the [snmp-server location](#) command to set the sysLocation.

**Samples** `bstnA(cfg)# snmp-server contact "jpublic, jpublic@mycompany.com"`  
sets the sysContact MIB object for the ARX.

`bstnA(cfg)# no snmp-server contact`  
erases the setting for the sysContact MIB object.

**Related Commands** [hostname](#)  
[snmp-server location](#)

---

# snmp-server host

- Purpose** Use the `snmp-server host` command to configure a target for SNMP notifications (such as SNMP traps).  
Use the `no` form of the command to remove an SNMP server from the list.
- Mode** `cfg`
- Security Role(s)** `network-engineer` or `crypto-officer`
- Syntax** `snmp-server host host-ip community-string [udp-port]`  
`no snmp-server host host-ip`
- host-ip* is the IP address of the SNMP host (for example, 192.168.70.65).  
*community-string* (up to 16 characters) is sent in each SNMP packet.  
*udp-port* (optional; 1-65535) is the UDP port where the remote host is listening for SNMP notifications. For most SNMP hosts, the default (162) is sufficient.
- Default(s)** 162, the well-known port for SNMP notifications, is the default *udp-port*.
- Guidelines** You can use this command multiple times to define up to 6 trap destinations.  
Use the [snmp-server traps](#) command to enable SNMP traps.  
For communication with an SNMP server (host access or trap transmission), you must also permit access to the SNMP agent through the internal firewall. Use the [management access snmp](#) command to edit the rules for SNMP, then use the [permit](#) command to permit server access through the out-of-band management interface (labeled MGMT on the front panel), the in-band (VLAN) management interface(s), or both.
- Samples** `bstnA(cfg)# snmp-server host 10.1.1.68 public`  
`bstnA(cfg)# snmp-server host 172.16.100.101 public`  
sets two destinations for SNMP notifications.
- `bstnA(cfg)# no snmp-server host 192.168.25.215`  
removes the SNMP host at 192.168.25.215 from the list of trap destinations.
- Related Commands** [snmp-server traps](#)  
[management access](#) -> [permit](#)

## snmp-server location

- Purpose** Use the `snmp-server location` command to enter location information (sysLocation, MIB-2.1.1.6) for the ARX.  
Use the `no` form of the command to clear the sysLocation setting.
- Mode** `cfg`
- Security Role(s)** `network-engineer` or `crypto-officer`
- Syntax** `snmp-server location location-info`  
`no snmp-server location`
- location-info* (1-255 characters) is the SNMP-server location information. Use quotation marks around the string if it contains any spaces.
- Default(s)** No location information is set.
- Guidelines** The sysLocation MIB object is part of the MIB-2.system tree, MIB-2.1.1.6. Use the [hostname](#) command to set the sysName object, and use the [snmp-server contact](#) command to set the sysContact.
- Samples** `bstnA(cfg)# snmp-server location "2nd floor lab, row 3, bay 4, shelf 5"`  
sets the sysLocation MIB object for the ARX.
- `bstnA(cfg)# no snmp-server location`  
clears the sysLocation object for the ARX.
- Related Commands** [hostname](#)  
[snmp-server contact](#)

## snmp-server name

**Purpose** Use the `snmp-server name` command to enter a new SNMP-advertised name for the ARX (sysName, MIB-2.1.1.5).

Use the `no` form of the command to erase the name.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `snmp-server name machine-name`  
`no snmp-server name [machine-name]`

*machine-name* (1 to 255 characters) is the administrative name of the server.

**Default(s)** `None`

**Guidelines** The `sysName` MIB object is part of the MIB-2.system tree, MIB-2.1.1.5. Use the [snmp-server location](#) command to set the `sysLocation` object, and use the [snmp-server contact](#) command to set the `sysContact`.

**Sample** `bstnA(cfg)# snmp-server name acopia1`  
sets the `sysName` MIB object for the “bstnA” ARX.

**Related Commands** [snmp-server location](#)  
[snmp-server contact](#)

## snmp-server traps

**Purpose** Use the `snmp-server traps` command to enable SNMP traps from the ARX.  
Use the `no snmp-server traps` command to disable SNMP traps.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `snmp-server traps [private]`  
`no snmp-server traps`

**private** (optional) enables only private traps, and disables the standard generic traps defined in RFC 1157. If you omit this option, the command enables all traps. Private traps are the enterprise traps defined specifically for the ARX. For a full list of F5's ARX-enterprise (private) traps, see the [ARX SNMP Reference](#).

**Default(s)** all traps enabled

**Guidelines** This command enables all SNMP traps, with an option to omit the generic traps and only use private (ARX) traps. The *generic* traps are defined in RFC 1157, the specification for SNMP, as one of the following:

- `coldStart`
- `warmStart`
- `linkDown`
- `linkUp`
- `authenticationFailure`
- `entityConfigChange` (defined in the RFC as an `enterpriseSpecific` trap)

Use the `snmp-server host` command to provide a destination for SNMP traps.

For communication with an SNMP server (host access or trap transmission), you must also permit access to the SNMP agent through the internal firewall. Use the `management access snmp` command to edit the rules for SNMP, then use the `permit` command to permit server access through the out-of-band management interface (labeled MGMT on the front panel), the in-band (VLAN) management interface(s), or both.

If you are sending traps out through a `channel` on the client/server VLANs, use `no trap shutdown` to enable SNMP traps on the channel.

**Samples** `bstnA(cfg)# snmp-server traps`  
enables all trap types.

`bstnA(cfg)# no snmp-server traps`  
disables all traps.

**Related Commands** `snmp-server host`  
`management access -> permit`  
`no trap shutdown`

---

## snmp-server trusthost

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Purpose</b>          | Use the <code>snmp-server trusthost</code> command to permit SNMP gets and sets from a remote host.<br><br>Use the <code>no</code> form of the command to remove an SNMP host from the list of trusted hosts.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>           | <code>snmp-server trusthost <i>host-ip</i></code><br><code>no snmp-server trusthost <i>host-ip</i></code><br><br><i>host-ip</i> is the IP address of the SNMP host (for example, 192.168.70.65).                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default(s)</b>       | All hosts are trusted (if they use the string(s) specified through <a href="#">snmp-server community</a> ) until you limit the number of trusted hosts with this command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>       | You can use this command multiple times to configure up to 8 trusted hosts. Before you use this command, all hosts are trusted (though they are denied access through the firewall; see below).<br><br>For communication with an SNMP server (host access or trap transmission), you must also permit access to the SNMP agent through the internal firewall. Use the <a href="#">management access snmp</a> command to edit the rules for SNMP, then use the <a href="#">permit</a> command to permit server access through the out-of-band management interface (labeled MGMT on the front panel), the in-band (VLAN) management interface(s), or both. |
| <b>Samples</b>          | <code>bstnA(cfg)# snmp-server trusthost 10.1.1.68</code><br>allows the SNMP host at 10.1.1.68 to access the local SNMP agent.<br><br><code>bstnA(cfg)# no snmp-server trusthost 172.16.100.101</code><br>removes the SNMP host at 172.16.100.101. The local SNMP agent will no longer accept SNMP gets or sets from that IP address.                                                                                                                                                                                                                                                                                                                      |
| <b>Related Commands</b> | <a href="#">snmp-server community</a><br><a href="#">management access</a> -> <a href="#">permit</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

---

## Email Notifications (SMTP)

---

---

You can set up the Simple Mail Transfer Protocol (SMTP) to send email notifications for ARX events.

---

# clear smtp queue

**Purpose** The SMTP *mail queue* holds email messages until they are successfully delivered. Use the `clear smtp queue` command to delete all such queued messages.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `clear smtp queue`

**Default** None

**Guidelines** Messages are only in the mail queue for a very short time before the first attempt to deliver them. If you can see a message with [show smtp queue](#), the message has not yet been successfully delivered. Use this command to delete all messages from the queue.

After deleting the messages, this shows information about each message: the “To” and “From” fields, the size, and the age (time in the mail queue).

Alternatively, you can retry all queued messages with [smtp retry](#).

Use [show smtp status](#) to see details on the most-recent message delivery, and to view the current configuration for SMTP.

**Sample** `bstnA# clear smtp queue`

```
To: juser@wwmed.com From:admin@wwmed.com Size:393.00 Age:5h has been
deleted.
```

```
To: juser@wwmed.com From:admin@wwmed.com Size:393.00 Age:5h has been
deleted.
```

```
To: juser@wwmed.com From:admin@wwmed.com Size:393.00 Age:19m has
been deleted.
```

```
To: juser@wwmed.com From:admin@wwmed.com Size:393.00 Age:18m has
been deleted.
```

```
bstnA#
```

```
clears four pending email messages.
```

# email-event

**Purpose** Use the `email-event` command to start defining a set of ARX events to be emailed, the conditions under which the switch sends the email(s), and any recipients who should receive them. This creates a profile, or *role*, for one or more users who require event notification.

Use `no email-event` to remove an email event role.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `email-event role`  
`no email-event role`

*role* (1-128 characters) is a name that you choose for this set of email events, trigger conditions, and mail recipients (for example, “nocGroup”).

**Default** “tech-support” is a default email event role, shipped from the factory

**Guidelines** Before an `email-event` can notify any users of system events, `smtp` must be configured for this ARX.

This command places you in `cfg-email-event` mode, where you can access several commands that define the email event role. To enable groups of events at a time, use the `group (cfg-email-event)` command. You can also use this command to set thresholds or schedules for email notification (for example, send for every 3 occurrences of a group event, or once each week). You can enable individual events with the `group ... event` command, which can also override any default-threshold settings made for the event’s group. The `mail-to (cfg-email-event)` command chooses an email recipient for this set of events; enter this command once for each desired recipient. You can use the `description (cfg-email-event)` command to add an optional description to the email event configuration; this appears in the output of `show email-event`. Use `enable (cfg-email-event)` to enable all of the rules in this email event configuration. Notification does not begin until you enable the email event role.

You can reuse the `email-event` command to define multiple email event roles.

Email messages have a field in the SMTP header where you can set a severity level. SMTP servers can use this field for sorting and flagging incoming messages; the server at F5 Support is configured to use this field for prioritizing customer issues. Use the `email-severity` command to set the email severity for a given event. The `show email-severity` command shows event severities.

To send a small test message to all configured email recipients, use the `smtp test email-event` command. After a successful test, you can use `smtp welcome` to send an introductory email to all of the recipients.

This email delivery mechanism can be used together with standard SNMP-trap delivery. Use `snmp-server traps` to start setting up SNMP traps.

**Samples**    `bstnA(cfg)# email-event noc3`  
              `bstnA(cfg-email-event[noc3])# ...`  
                  creates an email event role named “noc3.”

`bstnA(cfg)# no email-event testEmail`  
                  removes an email event configuration.

                          [smtp welcome](#)

---

# email-severity

**Purpose** You can use the email-event feature to send emails to one or more users (possibly including F5 Support) for certain SNMP traps. A field in the SMTP-message header contains the severity for the message. This field is not shown in most email applications, but email servers can use it for prioritization. Use the `email-severity` command to modify the email severity for a particular event. Use `no email-severity` to revert to a default email severity.

**Mode** `cfg`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `email-severity event-name level {normal | warn | minor | major | critical}`  
`no email-severity event-name`

*event-name* (1-64 characters) identifies an event. An event corresponds to one SNMP trap, cataloged in the [ARX SNMP Reference](#). Use a `?` after the `email-severity` keyword for a full list of eligible email events (for example, `email-severity ?`).

`normal | warn | minor | major | critical` sets the severity for the event's email messages.

**Default** Defaults vary for each event; use `show email-severity all` to see them.

**Guidelines** To send SNMP traps in email, configure `smtp` and then set up at least one `email-event` role.

Use this command to set a severity level for an event's email messages. The severity level appears in a customized field in the SMTP header, "X-ARX-Severity." SMTP servers can use this field for sorting and flagging messages; the SMTP server at F5 Support is configured to sort email messages by this setting. You can use this to prioritize your events for Customer Support.

Each severity that you set with this command is system-wide; it applies to any email-event role that uses the event.

Use `show email-severity` to show the current severities for one or more events.

**Samples** `bstnA(cfg)# email-severity auto-reboot level critical`  
sets the email severity to "critical" for an "auto-reboot" event.

`bstnA(cfg)# no email-severity disk-state`  
resets the "disk-state" event to a "normal" severity.

**Related Commands** [show email-severity](#)  
[smtp](#)  
[email-event](#)

## enable (cfg-email-event)

**Purpose** You can define one or more SNMP-trap events to be emailed to one or more users, as well as the thresholds for sending each event. One collection of events, thresholds, and users is called an email event *role*. Use the **enable** command to activate the current role.

Use **no enable** to disable the current email event role.

**Mode** `cfg-email-event`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** **enable**  
**no enable**

**Default(s)** Disabled

**Guidelines** You must enable an email event role to activate it.

**Samples** `bstnA(cfg-email-event[noc3])# enable`  
enables the current email event role, `noc3`.

`bstnA(cfg-email-event[betaTest])# no enable`  
disables the “betaTest” role.

**Related Commands** [email-event](#)

---

## from (cfg-smtp)

**Purpose** Use the `from` command to set the “From” field in all email messages from the ARX. Use `no from` to revert to the default “From” string.

**Mode** `cfg-smtp`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `from hostname@domain`  
`no from`

*hostname@domain* is 1-132 characters (for example, “admin@arx1000-B.nemed.com”). Use only alphabetical characters (a-z and A-Z), numeric characters (0-9), - (dash), \_ (underscore), and/or . (period).

**Defaults** None

**Guidelines** The string you set with this command appears in the header of all email messages, in the “From” field.

Enter an email address that uses acceptable characters (listed above in *Syntax*). If there are any invalid characters, the CLI rejects the string with an error.

To see the current setting for the “From” field, use the [show smtp status](#) command.

**Samples** `bstnA(cfg-smtp)# from aco_admin@acopia.wmed.com`  
sets the “From” field for all outgoing messages.

`bstnA(cfg-smtp)# no from`  
erases the “From” string and reverts to the default.

**Related Commands** [smtp](#)

## group (cfg-email-event)

**Purpose** You can define SNMP-trap events to be emailed to one or more users, as well as the thresholds for sending each event. One collection of events, thresholds, and users is called an email event *role*. Use the **group** command to add an entire group of events to an email event role.

Use the **no** form to remove a group of events from a role.

**Mode** cfg-email-event

**Security Role(s)** network-engineer or crypto-officer

**Syntax** **group** *group-name* [**threshold-counter** *counter* | **threshold-interval** *time* {minutes | hours | days}]

**no group** *group-name* [**threshold-counter** *counter* | **threshold-interval** *time* {minutes | hours | days}]

*group-name* is **chassis**, **cifs**, **storage**, **metadata**, **nsck**, **policy**, **snapshot**, **stats-monitor**, **virtual-server**, **network**, **redundancy** (for any chassis except the ARX-VE), or **all**.

**threshold-counter** *counter* (optional, 1-128) sets a threshold based on the number of events that occur from this group. For example, **threshold-counter 4** means that each event from this group triggers an email if it occurs 4 times.

**threshold-interval** *time* {minutes | hours | days} (optional) sets a schedule for this group. For example, **threshold-interval 1 days** causes the system to accumulate traps throughout the day and, if there are any, send a single email describing all of them. All time calculations begin when you enter this configuration; if the threshold interval is 1 day, the switch sends the email at the current time of day.

**Default** no groups enabled

If you enable a group without setting any threshold, the default is **threshold-counter 1**.

**Platforms** You cannot choose the **redundancy** group on the ARX-VE.

---

**Guidelines** This command enables one group of events for the current email event role. Whenever the system reaches a threshold you set with this command, it sends an email to any or all [mail-to \(cfg-email-event\)](#) recipients. You can optionally use the [group ... event](#) command to configure a single event in the group, or to set a different threshold for a particular event.

The system keeps a maximum of 128 events for any event group. This is a hard threshold, even if you use the `threshold-interval` option to create a time-based schedule. For example, suppose you configure the following:

```
group cifs threshold-interval 7 days
```

This sends an email every week. However, if 128 CIFS events occur before the week is over, the system delivers an interim email with those events. This resets the start time for the 7-day schedule: the ARX delivers the next set of CIFS events 7 days later, or after 128 more events, whichever comes first.

If you use [group ... event](#) to add a specific event, the `no group` command for its group does not delete that event. For example, the following command sequence does not delete the “warmstart” event:

```
group chassis event warmstart
no group chassis
```

**Samples** `bstnA(cfg-email-event[noc3])# group chassis`  
adds the group of “chassis” events to this email role. This command uses the default threshold; every chassis event triggers an email as soon as it happens.

`bstnA(cfg-email-event[noc3])# group metadata threshold-counter 5`  
adds the group of “metadata” events to this email role. Every 5th metadata event triggers an email.

`bstnA(cfg-email-event[noc3])# no group storage`  
removes the “storage” event group. This prevents any storage-group events from triggering emails.

**Related Commands** [email-event](#)  
[group ... event](#)

## group ... event

**Purpose** You can define one or more SNMP-trap events to be emailed to one or more users, as well as the thresholds for sending each event. One collection of events, thresholds, and users is called an email event *role*. Use the `group ... event` command to add one event to an email event role.

Use the `no` form to remove an event from a role, or to revert its threshold to the group default.

**Mode** `cfg-email-event`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `group group-name event event-name [threshold-counter counter | threshold-interval time {minutes | hours | days}]`  
`no group group-name event event-name [threshold-counter counter | threshold-interval time {minutes | hours | days}]`

*group-name* is `chassis`, `cifs`, `storage`, `metadata`, `nsck`, `policy`, `snapshot`, `stats-monitor`, `virtual-server`, `network`, `redundancy` (for any chassis except the ARX-VE), or `all`.

*event-name* (1-64 characters) is one of the events in the group. Each of these corresponds to one SNMP trap, cataloged in the [ARX SNMP Reference](#). Use a `?` after the `event` keyword for a full list of events in this group (for example, `group chassis event ?`).

**threshold-counter counter** (optional, 1-128) sets a threshold based on the number of times this event occurs. For example, **threshold-counter 4** means that any four occurrences trigger an email.

**threshold-interval time {minutes | hours | days}** (optional) sets a schedule for this event. For example, **threshold-interval 1 days** causes the system to accumulate instances of this event throughout the day and, if there are any, send a single email describing all of them. All time calculations begin when you enter this configuration; if the threshold interval is 1 day, the switch sends the email at the current time of day.

**Default** All defaults are defined by the event's group (see [group \(cfg-email-event\)](#)).

**Platforms** You cannot choose the `redundancy` group on the ARX-VE.

**Guidelines** This command enables one event for the current email event role. Whenever the system reaches its threshold for this event, it sends an email to any or all [mail-to \(cfg-email-event\)](#) recipients for this role.

If you do not set any threshold for an event, its group threshold is used (as set by the [group \(cfg-email-event\)](#) command).

The `no` form of the command disables the event's threshold (so that the event defaults to the threshold for its group), or removes the event altogether. See the *Samples*, below.

---

**Samples** `bstnA(cfg-email-event[noc3])# group metadata event online threshold-counter 2`  
adds one “metadata” event, “online,” to this email role. The threshold is 2 events; the system sends an email for every second event that indicates that a metadata share is online.

`bstnA(cfg-email-event[testteam])# group virtual-server event server-offline`  
adds the “server-offline” event to email event role, “testteam.” The threshold defaults to whatever threshold is set for the “virtual-server” group.

`bstnA(cfg-email-event[noc3])# no group metadata event online threshold-counter 2`  
reverts the “online” event to the default threshold. This default is defined by the “metadata” group.

`bstnA(cfg-email-event[noc3])# no group chassis event cpu-status`  
removes the “cpu-status” event from this email event role.

**Related Commands** [email-event](#)  
[mail-to \(cfg-email-event\)](#)  
[group \(cfg-email-event\)](#)

## mail-server

**Purpose** The mail-server command identifies the next-hop email server for the ARX.  
Use no mail-server to delete the email server name.

**Mode** cfg-smtp

**Security Role(s)** network-engineer or crypto-officer

**Syntax** mail-server *ip-or-name*  
no mail-server

*ip-or-name* (1-132 characters) identifies the mail server, either by IP address or DNS name (for example, “192.168.25.44” or “mailServer3.myco.com”).

**Default** None

**Guidelines** This is required for SMTP to function. This is the local mail server to deliver the ARX’s email messages to the WAN.  
You must have a DNS server configured to use a DNS name in this command. Refer to the [ip name-server](#) documentation to configure a DNS server.  
To see the currently configured mail server, use the [show smtp status](#) command. To test the mail-server configuration, use the [smtp test server](#) command.

 **Important**

---

*The no mail server command disables all email deliveries.*

**Sample** bstnA(cfg-smtp)# mail-server email1.wmed.com  
identifies the mail server.

**Related Commands** [smtp](#)  
[smtp test server](#)  
[ip name-server](#)

---

## mail-to (cfg-email-event)

**Purpose** You can define one or more SNMP-trap events to be emailed to one or more users, as well as the thresholds for sending each event. One collection of events, thresholds, and users is called an email event *role*. Use the `mail-to` command to set one destination address for the current role's emails.

Use the `no mail-to` command to remove an email recipient.

**Mode** `cfg-email-event`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `mail-to recipient`  
`no mail-to recipient`

*recipient* (1-768 characters) is one email recipient (for example, "juser@nemed.com").

**Default** `None`

**Guidelines** This sets a destination for all emails from this email event role; this address appears in the "To" field of the emails. You can enter this command multiple times, once for each recipient. At least five separate destinations are supported.

A sample email appears in [Figure 13.1 on page 13-15](#). You can use the ID (highlighted in the sample) to look up the trap in the [ARX SNMP Reference](#).

**Samples** `bstnA(cfg-email-event[noc3])# mail-to juser@wwmed.com`  
 sets up one email recipient for the "noc3" role. If a system event triggers a threshold, the system sends an email notification to `juser@wwmed.com`.

`bstnA(cfg-email-event[noc3])# no mail-to ex@nemed.com`  
 removes an email recipient from the "noc3" role.

**Related Commands** [email-event](#)

## maximum age

**Purpose** When the ARX fails to deliver an email message, it retries periodically. If the failures persist for too long, the ARX deletes the message. Use the **maximum age** command to determine the maximum amount of time to retry before deleting the message.  
Use **no maximum age** to return to the default.

**Mode** cfg-smtp

**Security Role(s)** network-engineer or crypto-officer

**Syntax** **maximum age** *days*  
**no maximum age**

*days* (1-366) is the number of days to retry before deleting the message.

**Default** 4 (days)

**Guidelines** The ARX retries a message every *n* minutes for the first two hours; you can use [retry interval](#) to set the value of *n*. The retry interval increases geometrically if the failures persist. After some number of days without success (set by this command, **maximum age**), the switch deletes the message from the mail queue.

Use [show smtp queue](#) to view all messages currently in the mail queue. These are the messages that have failed and are being saved for retries. You can use [smtp retry](#) to retry all queued messages now. The [clear smtp queue](#) command deletes all the messages without sending them.

**Samples** `bstnA(cfg-smtp)# maximum age 30`  
keeps all failed emails for up to 30 days before deleting them.

`bstnA(cfg-smtp)# no maximum age`  
reverts to the default.

**Related Commands** [smtp](#)  
[retry interval](#)  
[smtp retry](#)  
[clear smtp queue](#)

---

# retry interval

**Purpose** When the ARX fails to deliver an email message, it waits for some number of minutes before retrying. Use the `retry interval` command to set the initial interval between retries.

Use `no retry interval` to return to the default interval.

**Mode** `cfg-smtp`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `retry interval minutes`  
`no retry interval`

*minutes* (1-119) is the number of minutes to wait between email retries.

**Default** 15 (minutes)

**Guidelines** The ARX retries a message every *n* minutes for the first two hours; this command sets the value of *n*. The retry interval increases geometrically if the failures persist. After some number days without success (set by [maximum age](#)), the switch deletes the message from the mail queue.

Use [show smtp queue](#) to view all messages currently in the mail queue. These are the messages that have failed and are being saved for retries. You can use [smtp retry](#) to retry all queued messages now. The [clear smtp queue](#) command deletes all the messages without sending them.

**Samples** `bstnA(cfg-smtp)# retry interval 10`  
sets a 10-minute interval.

`bstnA(cfg-smtp)# no retry interval`  
reverts to the default interval.

**Related Commands** [smtp](#)  
[maximum age](#)  
[show smtp queue](#)  
[smtp retry](#)  
[clear smtp queue](#)

## show email-event

**Purpose** You can define one or more SNMP-trap events to be emailed to one or more users, as well as the thresholds for sending each event. One collection of events, thresholds, and users can be applied to technicians with a certain *role*. Use the `show email-event` command to see the configuration for one or all email event roles.

**Mode** (all)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show email-event {role-name | all}`

*role-name* (1-128 characters) is one role (for example, “tech-support”).

**all** selects all roles.

**Guidelines** The output contains up to four tables per email event role.

SMTP shows a summary of the SMTP settings for this ARX:

**From** is used in the “From” field of all emails. You can set this with [from \(cfg-smtp\)](#).

**Local Mail Server** is the SMTP server that is the next hop for all emails. You can set this with [mail-server](#).

Email Event describes the configuration of one email-event role:

**Role** is the name of the email-event role, set with the [email-event](#) command.

**Description** shows the optional description for this role. You can use the [description \(cfg-email-event\)](#) command to set (or change) this description.

**To** is a comma-separated list of email recipients. You can add one with the [mail-to \(cfg-email-event\)](#) command.

**Admin State** shows whether or not this role is enabled. Use [enable \(cfg-email-event\)](#) to enable the role.

The next table only appears if at least one event group is defined. It contains one row per event group, with the following columns in each row:

**Group Name** is set with the [group \(cfg-email-event\)](#) command.

**Threshold Counter** is either a number or “n/a.” If this many events from the group occur, the system sends an email. This is set with the [threshold-counter](#) option in the above [group](#) command.

**Threshold Interval (every)** is either time value (such as “2 hours” or “7 days”) or “n/a.” If any events from the group occur during this time, the system sends an email at the end of the time interval. This is set with the [threshold-interval](#) option in the [group](#) command.

**Guidelines (Cont.)** The next table only appears if at least one individual event is defined. It contains one row per event, with the following columns in each row:

Group Name is set with the `group ... event` command.

Event Name is set with the same command.

Threshold Counter is either a number or “n/a.” If this many instances of the event occur, the system sends an email. This is set with the `threshold-counter` option in the `group ... event` command.

Threshold Interval (every) is either time value (such as “10 minutes” or “12 hours”) or “n/a.” If any instances of this event occur during this time, the system sends an email at the end of the time interval. This is set with the `threshold-interval` option in the `group ... event` command.

**Samples** `bstnA# show email-event all`  
shows all email event roles. See [Figure 13.2 on page 13-19](#) for sample output.

`bstnA# show email-event noc3`  
shows the configuration for one email event role. See [Figure 13.3 on page 13-20](#) for sample output.

## show email-severity

**Purpose** You can set up SNMP-trap events to be emailed to one or more users, and you can use a separate command to set the severity of each event’s email message. The severity is expressed in a hidden field in the email header, which email servers can use for flagging and prioritizing email messages. Use the `show email-severity` command to see the severities for this switch’s email events.

**Mode** (all)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show email-severity {event-name | all | non-default}`

*event-name* (1-64 characters) is one event (for example, “module-failure”).

**all** shows all events.

**non-default** shows any events that have a non-default severity.

**Guidelines** The output is a table with two columns: Event Name and Severity. You can use the `email-severity` command to reset the severity.

**Samples** `bstnA# show email-severity all`  
shows all email events and their current severity settings. See [Figure 13.4 on page 13-21](#) for sample output.

`bstnA# show email-severity non-default`  
shows the email events whose severities have been reset. See [Figure 13.5 on page 13-25](#) for sample output.

`bstnA# show email-severity nvram-battery-failure`  
shows the severity for a particular email event. See [Figure 13.6 on page 13-25](#) for sample output.

**Related Commands** [email-severity](#)  
[email-event](#)

*Figure 13.4 Sample Output: show email-severity all*

```
bstnA# show email-severity all

| nvram-battery-failure | critical |

## show smtp queue

- Purpose** Use the `show smtp queue` command to see the email messages that are queued for delivery, if any.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show smtp queue`

**Guidelines** This command is used to see messages that failed delivery. email messages are in the queue for a very short time before they are sent out to the mail server; they stay in the queue longer if the delivery failed. Therefore, if all messages deliver on the first try, this command shows no messages in the queue.

The output is a table with two rows per message. The top row contains the following fields:

**Status** is “pending,” to indicate that the message is waiting for final delivery.

**From** can be reset (for future emails) with `from (cfg-smtp)`.

**Size** is in bytes if no unit (K, M, G, or T) appears after the number. K is for KiloBytes (1024 bytes), M is for MegaBytes (1024\*1024 bytes), and so forth.

The bottom row contains two more fields:

**Time** is when the message was created.

**To** can be reset for future emails with `to`.

The ARX retries a message every few minutes (set by `retry interval`) for the first two hours. This retry interval increases geometrically if the failures persist. After some days without success (set by `maximum age`), the switch deletes the message from the mail queue. You can use `smtp retry` to retry all queued messages now. The `clear smtp queue` command deletes all the messages without sending them.

Use `show smtp status` to see details on the most-recent message delivery, and to view the current configuration for SMTP.

**Sample** `bstnA# show smtp queue`  
shows the queue of pending email messages, if any. See [Figure 13.7](#) for sample output.

**Related Commands** `smtp`  
`to`  
`from (cfg-smtp)`  
`smtp retry`  
`show smtp status`

*Figure 13.7 Sample Output: show smtp queue*

```
bstnA# show smtp queue

show smtp queue
Status From To Size
Time

```

show smtp queue

---

```
pending admin@wwmed.com 461.00
 10/16/2007 13:33:51 GMT juser@wwmed.com
pending admin@wwmed.com 461.00
 10/16/2007 13:37:1 GMT juser@wwmed.com
```

## show smtp status

- Purpose** Use the `show smtp status` command to see the status of the most recent outbound email, as well as all SMTP-configuration settings.
- Mode** (all)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show smtp status`
- Guidelines** SMTP Last Transfer shows the last email message that was collected for delivery. This is not the most-recent retry; it is the most-recent message (or test) that was generated.
- **Last file** is the file name and size for the attachment file.
  - **Status** shows the status of the most-recent delivery:
    - **Success**
    - **Delivered to *mail-server***
    - **Deferred** means that the message has been added to the mail queue.
    - **Configuration error** means that the configuration is missing some information. (see the **SMTP Current Configuration** section, below)
    - **Could not communicate with mailserver** indicates a network problem, a DNS-configuration error, or an SMTP configuration error (such as the wrong name for [mail-server](#)).
    - **Message size exceeds limit** means that the local mailserver did not accept the large attachment with the file. You must configure the mail server to allow *very* large email attachments.
    - **Unable to relay**
    - **Insufficient disk space** indicates that there is not enough disk space to add the message to the mail queue.

**Guidelines (Cont.)**

- Error building mail header,
- SMTP error,
- Internal error mailing file, and
- Error uuencoding file are internal problems.

Message Created is the time when the message was first generated.

The remaining fields show the header for the email message.

SMTP Current Configuration shows the configuration that is in effect. This configuration will be applied to current and future email messages.

To can be set with [to](#).

From can be set with [from \(cfg-smtp\)](#).

Via is the SMTP server that is the next hop for all emails. You can set this with [mail-server](#).

Retry Interval is the time between retries for messages in the mail queue. The ARX uses this interval for the first two hours, then starts using larger intervals if the failures persist. You can set this initial interval with the [retry interval](#) command.

Maximum Age is maximum number of days to keep a message in the mail queue before deleting it. Use [maximum age](#) to set this value.

Use [show smtp queue](#) to see any pending email messages. To send a test message, use [smtp test message](#). If messages are failing, you can run [smtp test server](#) to test SMTP communication with the local email server.

**Sample**

```
bstnA# show smtp status
```

shows the SMTP status for the current switch. See [Figure 13.8](#) for sample output.

**Related Commands**

```
smtp
to
from (cfg-smtp)
mail-server
show smtp queue
smtp test message
smtp test server
```

*Figure 13.8 Sample Output: show smtp status*

## Chapter 13

### Email Notifications (SMTP)

---

Via: email1.wmed.com  
Retry Interval: 10 minutes  
Maximum Age: 30 days

# show smtp welcome

**Purpose** You can use the [smtp welcome](#) command to send an introductory email to all users of an email-event role. Use the `show smtp welcome` command to see the welcome message for this introductory email.

**Mode** (all)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show smtp welcome`

**Guidelines** This command displays the welcome message that appears at the top of an [smtp welcome](#) email.

**Sample**

```
bstnA# show smtp welcome
Welcome to the "<EMAIL_EVENT_ROLE>" role.
The host <HOSTNAME> will send email to you based on the following
events:
 shows the outline of the welcome message. The <EMAIL_EVENT_ROLE>
 variable is replaced by the role's name (set with email-event), and the
 <HOSTNAME> is replaced by the ARX's host name (set with hostname).
```

**Related Commands** [smtp welcome](#)  
[smtp](#)  
[email-event](#)  
[hostname](#)

## smtp

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                           | The ARX uses the Simple Mail Transfer Protocol (SMTP) to send email messages to other machines. Use the <code>smtp</code> command to begin SMTP configuration.<br><br>Use <code>no smtp</code> to erase all SMTP configuration parameters and disable email notifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Mode</b>                              | cfg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Security Role(s)</b>                  | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Default</b>                           | no smtp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Guidelines</b>                        | <p>You must configure DNS for the SMTP service to work. See the instructions for <a href="#">ip name-server</a>. You must have layer-2 and layer-3 connectivity to your server network(s) before DNS or SMTP can function.</p> <p>Use this command to enter <code>cfg-smtp</code> mode, where you set up the necessary parameters for email. You can use <code>from (cfg-smtp)</code> to set the “From” field in all out-bound emails (for example, “From: <i>hostname@domain</i>”). The <code>mail-server</code> command identifies the local mail server to be used as the next hop for mail messages. Use the <code>to</code> command to set one or more destinations for emails. If an email delivery fails, it retries at the frequency set by <code>retry interval</code>, up to a maximum number of days (<code>maximum age</code>). After the maximum age expires, the ARX deletes the message.</p>                                                                                                          |
| <b>Guidelines: Testing and Debugging</b> | To send a test message, use <code>smtp test message reply-to</code> with a local destination for the message. You can view any undelivered messages with the <code>show smtp queue</code> command. Use the <code>smtp retry</code> and <code>clear smtp queue</code> commands to manage this mail queue. If messages are consistently failing, you can run <code>smtp test server</code> to test SMTP communication with the local email server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines: Applications for SMTP</b> | <p>After you finish configuring SMTP, you can configure certain system events to be delivered in email messages. Each event is analogous to an SNMP trap; see the <a href="#">ARX SNMP Reference</a> for a full list of ARX Enterprise traps, including the traps that have email support. You can choose individual events or groups of them, one or more email recipients for the events, and thresholds (or a schedule) for sending the emails. All of these components can be assigned to technicians who perform a specific <i>role</i>. Use the <code>email-event</code> command to begin configuring one such role. You can create multiple roles by re-using this command.</p> <p>SMTP is also useful for sending collected diagnostics and other maintenance files over email. After you configure SMTP, use the <code>collect</code> command to collect and send diagnostics. You can also use <code>copy smtp</code> to send log files, reports, or other files that could be useful for maintenance.</p> |

---

**Samples**    `bstnA(cfg)# smtp`  
              `bstnA(cfg-smtp)# ...`  
                  starts SMTP configuration.

`bstnA(cfg)# no smtp`  
                  deletes all SMTP configuration and disables email notifications.

| <b>Purpose</b>          | The SMTP <i>mail queue</i> holds email messages until they are successfully delivered. Use the <code>smtp retry</code> command to retry all queued messages at once.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Default</b>          | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines</b>       | <p>This is particularly useful if there was a network problem between the ARX and the next-hop mail server (<a href="#">mail-server</a>). After you fix the network problem, you can use this command to re send all queued messages. You can use <a href="#">show smtp queue</a> to see the mail queue before and after the retry.</p> <p>As an alternative, you can use <a href="#">clear smtp queue</a> to remove all messages from the queue.</p> <p>For each message that is successfully delivered to the mail server, “Message sent” appears after the command. For each failed delivery, “Message deferred” appears.</p> <p>When you change a parameter in <code>cfg-smtp</code> mode (see <a href="#">smtp</a>) and then <code>exit</code> the mode, the ARX automatically retries all messages in the queue using the new parameters. There is no need to invoke this command under these circumstances.</p> <p>Use <a href="#">show smtp status</a> to see details on the most-recent message delivery, and to view the current configuration for SMTP.</p> |
| <b>Sample</b>           | <pre>bstnA# smtp retry</pre> <p>retries all pending email messages, if there are any.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

---

# smtp test email-event

**Purpose** Use the `smtp test email-event` command to test an [email-event](#) configuration. This sends a test email to all configured recipients.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `smtp test email-event role-name`

*role-name* (1-128 characters) is the role to test (for example, “tech-support”). Use [show email-event all](#) for a list of all configured email-event roles.

**Default** `None`

**Guidelines** Use this command to send an email message with a small test attachment. the message goes to all [mail-to \(cfg-email-event\)](#) recipients configured for the chosen [email-event](#) role. Use [show email-event \*role-name\*](#) to see all recipients for a given role. You can use this to verify the email-event configuration and SMTP setup.

If the message is successfully delivered to the next-hop [mail-server](#), a message appears similar to the following:

```
Message sent to juser@wwmed.com,jqpublic@wwmed.com.
```

An error appears if there is a delivery problem. In this case, you can use [show smtp queue](#) to see the test message in the mail queue. To retry the message (perhaps after correcting the network configuration), use [smtp retry](#). Use [clear smtp queue](#) to remove all messages from the queue. If the delivery problems persist, you can run an SMTP diagnostic test, [smtp test server](#), and send the output back to F5 for analysis.

Note that the test message has a small attachment, so this does not test any errors that may come up with large attachments. An attachment from [copy smtp](#) or [collect](#) can be hundreds of MegaBytes.

Use [show smtp status](#) to see details on the most-recent message delivery, and to view the current configuration for SMTP.

After a successful test, you can use the [smtp welcome](#) command to send a welcome message to all email recipients. This message informs the recipients of the events that will trigger email messages in the future.

**Sample** `bstnA# smtp test email-event noc3`

```
Message sent to juser@wwmed.com,jqpublic@wwmed.com for role "noc3".
```

successfully sends a test message to the recipients of the “noc3” email event. See [Figure 13.9](#) for a sample email.

Subject: Email Event Test for the event group noc3 for bstnA running 5.01.000.11891
```

This is a test of the email event mailer "noc3" on bstnA running 5.01.000.11891.

Email will be sent for events in the following groups:

| Group Name | Threshold |                 |
|------------|-----------|-----------------|
|            | Counter   | Interval(every) |
| chassis    | 1         | n/a             |
| metadata   | 5         | n/a             |

| Group Name | Event Name                              | Threshold |                 |
|------------|-----------------------------------------|-----------|-----------------|
|            |                                         | Counter   | Interval(every) |
| metadata   | online                                  | 2         | n/a             |
| redundancy | ha-pair-qd-offline                      | 1         | n/a             |
| storage    | share-online                            | 3         | n/a             |
| storage    | share-remove-complete                   | 1         | n/a             |

## smtp test message

**Purpose** Use the `smtp test message` command to send a test email message.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `smtp test message [reply-to user@domain]`

*user@domain* (optional, 1-256 characters) is an email destination for the test-message reply.

**Default** `reply-to user@domain` defaults to the setting of the `to` command if you omit the option.

**Guidelines** Use this command to send an email message with a small test attachment to an SMTP server at F5. This tests the SMTP configuration settings and the network connection to the local email server. You can use this to verify the SMTP setup.

The message is delivered to the next-hop [mail-server](#). An error appears if there is a delivery problem. In this case, or if no reply email arrives for 15 minutes or more, you can use [show smtp queue](#) to see the test message in the mail queue. Also, check the email filter at the destination mailbox. To retry the message (perhaps after correcting the network or filter configuration), use [smtp retry](#). Use [clear smtp queue](#) to remove all messages from the queue. If the delivery problems persist, you can run an SMTP diagnostic test, [smtp test server](#), and send the output back to F5 for analysis.

Note that the test message has a small attachment, so this does not test any errors that may come up with large attachments. An attachment from [copy smtp](#) or [collect](#) can be hundreds of MegaBytes.

Use [show smtp status](#) to see details on the most-recent message delivery, and to view the current configuration for SMTP.

**Sample** `bstnA# smtp test message reply-to jsmith@wwmed.com`

sends a test message to an SMTP server at F5. If the delivery succeeds, the F5 server will send a reply to “jsmith@wwmed.com.”

# smtp welcome

**Purpose** Use the `smtp welcome` command to send an introductory email message to all users in an [email-event](#) configuration. The introductory message informs the recipients of the types of system events they will be receiving through email.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `smtp welcome [role-name]`

*role-name* (optional, 1-128 characters) is the role to receive the email message (for example, “noc\_7”). Use [show email-event all](#) for a list of all configured email-event roles.

**Default** *role-name* defaults to all roles if you omit it. That is, the command sends a welcome message to all users in all email-event roles.

**Guidelines** Use this command to send an introductory email message to the recipients of email events. the message goes to all [mail-to \(cfg-email-event\)](#) recipients configured for the chosen [email-event](#) role (or all roles, if no specific role was selected). Use [show email-event role-name](#) to see all recipients for a given role.

If the message is successfully delivered to the next-hop [mail-server](#), a message appears similar to the following:

```
Message sent to juser@wwmed.com,jqpublic@wwmed.com.
```

Use [show smtp status](#) to see details on the most-recent message delivery, and to view the current configuration for SMTP. If the message fails, you can use [smtp test email-event](#) to test the email-event configuration and SMTP setup.

The email contains a welcome message and two tables to outline the types of events that the recipient can expect in email messages. The top table shows event groups, and the bottom table contains individual events that will trigger an email. The [show smtp welcome](#) command shows the format of the welcome message.

**Sample** `bstnA# smtp welcome noc3`

```
Message sent to to jqpublic@wwmed.com.
```

successfully sends a welcome message to the recipients of the “noc3” email event. See [Figure 13.11](#) for a sample email.

## to

**Purpose** Use the `to` command to set destination address(es) for emails from the ARX.  
Use the `no to` command to revert to the default destination.

**Mode** `cfg-smtp`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `to destination-list`  
`no to`

*destination-list* (1-1024 characters) is a comma-separated list of email recipients (for example, “`juser@nemed.com`” or “`jqpublic@wwmed.com,juser@nemed.com`”). Surround this field with quotation marks if it contains any spaces.

**Default** `e-support@f5.com`

**Guidelines** This sets the destination(s) for emails from the ARX; these addresses appear in the “To” field of the emails. These addresses only apply to emails from [collect](#), [copy smtp](#), and [smtp test message](#). Each [email-event](#) role has its own set of email recipients, configured with the [mail-to \(cfg-email-event\)](#) command.

The default address sends messages back to Technical Support at F5. For most running systems, this default is appropriate. You can use this command to test email notifications, or to send email to one or more different support organizations.

To change any address in the list, re-run this command with an entirely new list of addresses.

To see the current email destination(s), use the [show smtp status](#) command.

**Samples** `bstnA(cfg-smtp)# to “juser@das1.wwmed.com,e-support@f5.com”`  
sets two destinations for all outgoing messages.

`bstnA(cfg-smtp)# no to`  
resets the destination back to the default.

**Related Commands** [smtp](#)  
[show smtp status](#)  
[copy smtp](#)  
[collect](#)

# heartbeat failure

|                         |                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The ARX sends periodic heartbeats to check the health of the RON-tunnel connection. Use this command to determine the number of consecutive failures before declaring the tunnel “OFFLINE.”                          |
| <b>Mode</b>             | cfg-if-vlan-ron-tnl                                                                                                                                                                                                  |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                   |
| <b>Syntax</b>           | <b>heartbeat failure <i>max-failures</i></b><br><br><i>max-failures</i> (2-10) is the number of consecutive dropped heartbeats to tolerate <i>before</i> declaring a failure.                                        |
| <b>Default(s)</b>       | 4                                                                                                                                                                                                                    |
| <b>Guidelines</b>       | Use the <a href="#">heartbeat interval</a> command to set the number of seconds between heartbeats. Use the <a href="#">show ron</a> command to see the current connection state for all RON tunnels.                |
| <b>Sample</b>           | <pre>bstnA(cfg-if-vlan-ron-tnl[25~toPortland])# <b>heartbeat failure 6</b></pre> sets the threshold to 6 consecutive heartbeat failures. This interface declares the tunnel “OFFLINE” if 7 heartbeats fail in a row. |
| <b>Related Commands</b> | <a href="#">ron tunnel</a><br><a href="#">heartbeat interval</a><br><a href="#">show ron</a>                                                                                                                         |

## heartbeat interval

|                         |                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The ARX sends periodic heartbeats to check the RON-tunnel connection. Use this command to determine the number of seconds between heartbeats.                                                                                                  |
| <b>Mode</b>             | cfg-if-vlan-ron-tnl                                                                                                                                                                                                                            |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                             |
| <b>Syntax</b>           | <b>heartbeat interval <i>seconds</i></b><br><br><i>seconds</i> (1-30) is the number of seconds between heartbeats.                                                                                                                             |
| <b>Default(s)</b>       | 3                                                                                                                                                                                                                                              |
| <b>Guidelines</b>       | Use the <a href="#">heartbeat failure</a> command to set the number of dropped heartbeats to tolerate before declaring the tunnel “OFFLINE.” Use the <a href="#">show ron</a> command to see the current connection state for all RON tunnels. |
| <b>Sample</b>           | bstnA(cfg-if-vlan-ron-tnl[25~toPortland])# <b>heartbeat interval 15</b><br>sets a 15-second interval between RON heartbeats.                                                                                                                   |

---

## interface ron

**Purpose** \*\* Deprecated \*\*

Use this command to edit a legacy RON interface, one that was created before Software Release 2.0.

Use the **no** form of the command to remove a legacy RON interface. See the *Guidelines*, below.

**Mode** cfg

**Security Role(s)** network-engineer or crypto-officer

**Syntax** **interface ron *if-name***  
**no interface ron *if-name***

*if-name* (1-32 characters) identifies the legacy RON interface.

**Default(s)** None

**Guidelines** This command is deprecated, and exists only to edit the configuration of legacy RON interfaces and tunnels. Use [ron tunnel](#) to create a new RON tunnel, which terminates at an in-band (VLAN) management IP instead of an additional RON IP address. If possible, use [ron tunnel](#) to duplicate all legacy RON tunnels, go to the remote switch(es) and run the [peer address](#) command with the new RON-tunnel address, then use **no interface ron** to remove the legacy tunnels.

This command places you in `cfg-ron` mode. From there, use the [ip address \(cfg-ron\)](#) command to edit the local IP address, and the [peer address](#) command to change the peer's address. You can optionally tune the tunnel's health-check parameters by setting the [heartbeat interval](#) and the threshold for consecutive [heartbeat failure](#) events before declaring the link OFFLINE. Use `shutdown` to disable the interface.

To view the current state and configuration of all tunnels, use [show ron](#). For a full view of Link-State Advertisements from all switches connected via RON, use [show ron database](#).

If the tunnel is connected and you use **no interface ron**, the CLI prompts you before disconnecting it. Enter **yes** to continue.

**Samples** `bstnA(cfg)# interface ron haPeer`  
`bstnA(cfg-ron[haPeer])#`  
          edits the RON interface, "haPeer."

`bstnA(cfg)# no interface ron toPhilidelphia`  
Tunnel ''toPhilidelphia'' is currently connected.

Delete tunnel ''toPhilidelphia''? [yes/no] **yes**  
`bstnA(cfg)#`  
          removes the legacy "toPhilidelphia" interface.

**Related Commands** [ron tunnel](#)  
[show ron tunnel](#)

## ip address (cfg-ron)

**Purpose** \*\* Deprecated \*\*

Use this command to provide a local IP address for the current (legacy) RON interface.

**Mode** cfg-ron

**Security Role(s)** network-engineer or crypto-officer

**Syntax** `ip address address mask [vlan vlan-id]`

*address* is the IP address you choose for the RON interface (for example, 10.1.99.78).

*mask* defines the network part of the address (for example, 255.255.255.0).

*vlan vlan-id* (optional; 1-4096) specifies a VLAN to carry the tunnel.

**Default(s)** *vlan-id*: 1

### Guidelines

#### ◆ Note

---

*This command is unique to a legacy RON interface, which is deprecated in favor of the new [ron tunnel](#). Whenever possible, duplicate all legacy RON interfaces as RON tunnels, go to the remote switch(es) and run the [peer address](#) command with the new RON-tunnel address, then return to the local switch to delete the RON interfaces. (RON tunnels re-use an in-band-management IP, whereas RON interfaces require an additional IP address.)*

This address must also be configured at the other end of the RON tunnel as the [peer address](#); the tunnel is not functional until the configurations match at both switches.

This address must be unique from all proxy IPs, VIPs and management IPs.

**Samples** `bstnA(cfg-ron[toProv])# ip address 192.168.25.50 255.255.255.0`  
sets an IP address of 192.168.25.50 for the “toProv” interface.

`prt1ndB(cfg-ron[test])# ip address 192.168.74.73 255.255.255.0 vlan 96`  
sets the IP address for the “test” interface. This address is on VLAN 96.

**Related Commands** [interface ron](#)  
[ron tunnel](#)  
[peer address](#)

# ip private subnet reassign

|                         |                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Two switches in a RON are said to have a <i>conflict</i> if their private IP subnets are the same. Use this command to reassign a private subnet to the current switch and reboot it.                                                                                                                           |
| <b>Mode</b>             | cfg                                                                                                                                                                                                                                                                                                             |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                              |
| <b>Syntax</b>           | <b>ip private subnet reassign</b>                                                                                                                                                                                                                                                                               |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                            |
| <b>Guidelines</b>       | <p>Use the <a href="#">show ron</a> or <a href="#">show ron conflicts</a> command to confirm that this switch has a private subnet that conflicts with another.</p> <p>Note that this command reboots the current chassis. The CLI prompts for confirmation before rebooting; enter <b>yes</b> to continue.</p> |
| <b>Sample</b>           | <pre>bstnA(cfg)# ip private subnet reassign Reassign a new, unused, private subnet and reboot the chassis? [yes/no] yes ...</pre>                                                                                                                                                                               |
| <b>Related Commands</b> | <a href="#">ron tunnel</a><br><a href="#">show ron</a><br><a href="#">show ron conflicts</a>                                                                                                                                                                                                                    |

## peer address

|                         |                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use this command to provide the IP address for the remote end of the RON tunnel.                                                                                                                                                                                                                                                                                                       |
| <b>Mode</b>             | cfg-if-vlan-ron-tnl                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Security Role(s)</b> | network-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>           | <b>peer address <i>remote-address</i></b>                                                                                                                                                                                                                                                                                                                                              |
|                         | <i>remote-address</i> is the remote IP address (for example, 10.1.33.8) for the in-band (VLAN) interface at the other end of the tunnel.                                                                                                                                                                                                                                               |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines</b>       | Each end of the RON tunnel terminates at an in-band (VLAN) management interface, created with the <a href="#">interface vlan</a> command. This command identifies the management interface's <a href="#">ip address (cfg-if-vlan)</a> at the other end of the tunnel. At the other end of the tunnel, the <a href="#">peer address</a> points back to the local in-band-management IP. |
| <b>Sample</b>           | <pre>prtlndA(cfg-if-vlan-ron-tnl[74~toBoston])# peer address 192.168.25.5</pre> sets an IP address of 192.168.25.5 for the remote end of the “toBoston” tunnel.                                                                                                                                                                                                                        |
| <b>Related Commands</b> | <a href="#">ron tunnel</a><br><a href="#">ip address (cfg-if-vlan)</a>                                                                                                                                                                                                                                                                                                                 |

---

# rconsole

**Purpose** Use the `rconsole` command to start a new CLI session on an ARX at the other end of a RON tunnel.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `rconsole hostname [username]`

*hostname* (1-128 characters) is the remote switch name.

*username* (optional, 1-32 characters) is a valid administrative `user` account on the remote ARX. If you omit this, the command uses the name you used to log into the current CLI session. Note that this administrative account may not exist at the remote ARX, or may have a different password.

**Default(s)** *username* - the administrative account you used to log into the local CLI.

**Guidelines** The `rconsole` command starts a new CLI session on a remote ARX. This occurs through a Secure Shell (SSH). The other switch must be reachable using a RON tunnel, and the name of the switch must be known to RON. To see the current switch names available through RON, use the `show ron` command. Those switches showing the connection status 'ONLINE' are available through the `rconsole` command.

The remote CLI prompts you for a password. This is the password for the *username* account on the remote switch; administrative accounts are configured independently at every switch in the RON (see `user`). Passwords are not guaranteed to be consistent throughout a RON.

**Sample**  
bstnA# `rconsole prtlnDA admin`  
Password: `myP@55w0RD`  
prtlnDA>

starts a CLI session on the switch, 'prtlnDA' connected through the RON. This login uses "admin" as a user name.

**Related Commands** [ron tunnel](#)  
[show ron](#)  
[user](#)

## ron evict

**Purpose** Use this command to remove an offline ARX from the RON.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `ron evict host-name`

*host-name* (1-128 characters) is the name of the switch to remove from the RON.

**Default(s)** None

**Guidelines** If the switch is to be replaced, we recommend that you avoid this command. The [show ron](#) command shows the UUID for the former RON member, and this number is very important for a smooth switch replacement.

The switch must be offline to be evicted. This means that there can be no working RON tunnels to the switch. The `show ron` command shows whether or not the switch is offline.

**Sample** `bstnA# ron evict pawtucket`  
removes the switch, “pawtucket,” from the RON.

**Related Commands** [ron tunnel](#)  
[show ron](#)

---

## ron tunnel

**Purpose** Use this command to create one end of a resilient overlay network (RON) tunnel. RON tunnels are used for communication between two or more ARXes.

Use the **no** form of the command to remove a RON-tunnel interface (see *Guidelines* below).

**Mode** cfg-if-vlan

**Security Role(s)** network-engineer or crypto-officer

**Syntax** **ron tunnel** *name*  
**no ron tunnel** *name*

*name* (1-32 characters) is a name you choose for the RON tunnel.

**Default(s)** None

**Guidelines** Use this command to begin the configuration at one end of a RON tunnel. A RON tunnel terminates at an in-band (VLAN) management interface; use [interface vlan](#) to create such an interface. The in-band-management IP is the IP address of the RON tunnel's local end.

This command places you in `cfg-if-vlan-ron-tnl` mode. From there, use the [peer address](#) command to identify the peer's address (that is, the IP address of the peer's in-band management interface). You can optionally tune the tunnel's health-check parameters by setting the [heartbeat interval](#) and the threshold for consecutive [heartbeat failure](#) events before declaring the tunnel "OFFLINE." Then use **no shutdown (cfg-if-vlan-ron-tnl)** to enable the tunnel interface. To start traffic on the tunnel, repeat this process (reversing the IP addresses) at the other end.

Multiple RON tunnels can terminate in a single in-band management interface.

After you connect two switches with a RON tunnel, you can access the peer switch's CLI through the [rconsole](#) command.

The [show ron](#) command shows a high-level status for the entire RON. To view the current state and configuration of a tunnel, use [show ron tunnel](#). For a full view of Link-State Advertisements from all switches connected via RON, use [show ron database](#). Use [show ron conflicts](#) to see which switches (if any) have a private-subnet conflict; to resolve a conflict, use [ip private subnet reassign](#).

**Samples**

```
bstnA(cfg)# interface vlan 89
bstnA(cfg-if-vlan[89])# ron tunnel toEllesworth
bstnA(cfg-if-vlan-ron-tnl[toEllesworth])#
 creates the tunnel, "toEllesworth."
```

```
bstnA(cfg-if-vlan[89])# no ron tunnel toPhilidelphia
Tunnel ''toPhilidelphia'' is currently connected.
Delete tunnel ''toPhilidelphia''? [yes/no] yes
bstnA(cfg-if-vlan[89])#
 removes the tunnel, "toPhilidelphia."
```

**Related Commands** [interface vlan](#)  
[show ron tunnel](#)

## show ron

**Purpose** Use this command to display the current RON configuration and status.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator

**Syntax** `show ron [member]`

*member* (optional, 1-128 characters) specifies the hostname for one member of the RON. If you omit this, the command shows all RON members.

**Default(s)** None

**Guidelines** This command displays a two-line entry for each member of the RON. The first line identifies the switch and its high-level status.

**Switch Name** identifies the member switch.

**HA Peer Switch** for the switch, if there is one. This is the switch's redundant peer.

**Uptime** is the time since the switch's last reboot.

The second line has information about the RON (and possibly the redundant pair).

**Status** is ONLINE, OFFLINE, SUBNET CONFLICT, or unknown. The SUBNET CONFLICT status indicates that the private subnet is the same as some other switch in the RON; use [show ron conflicts](#) to find which switches conflict with which.

**UUID** is the Universally-Unique ID for the switch. All of the shares owned by this switch are marked with this UUID. In a redundant pair, a share is owned by a switch when its volume's [volume-group](#) is set at the switch. You set a switch's UUID during installation.

**Management Addr** is the Out-of-band MGMT interface, if configured.

Otherwise, it is the address of the in-band (VLAN) management interface of the lowest-numbered VLAN.

If you choose one *member*, the output focuses on that host only. The fields are the same, presented in a different format.

Use [ron tunnel](#) to create one end of a RON tunnel.

**Samples** `prt1ndA# show ron`  
displays all hosts in the RON. [Figure 14.1](#) shows a sample.

`prt1ndA# show ron prt1ndB`  
displays the RON status for one redundant peer. [Figure 14.2](#) shows a sample.

**Related Commands** [ron tunnel](#)

```

## show ron conflicts

**Purpose** Two switches in a RON are said to have a *conflict* if their private IP subnets are the same. The `show ron conflicts` command shows all conflicting switches in the current RON.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator

**Syntax** `show ron conflicts`

**Default(s)** None

**Guidelines** This shows a table of RON conflicts, one row per conflicting switch. The **Accessible Switch** is available from the local switch, and the **Conflicting Switch** is not; some other switch in the RON might show the same conflict with the switch roles reversed. Each of these switches can only communicate with a limited number of peers in the RON, if any. To correct the problem and bring conflicting switches fully into the RON, go to one conflicting switch and use [ip private subnet reassign](#).

**Sample** `prtlnDA> show ron conflicts`

| Accessible Switch | Conflicting Switch |
|-------------------|--------------------|
| -----             | -----              |
| BIG6000-WEST      | ARX-500-SJC        |

displays all private-subnet conflicts in the RON.

**Related Commands** [ip private subnet reassign](#)  
[ron tunnel](#)

| <b>Guidelines</b>       | <p>You can connect one ARX to another with a RON tunnel: use this command to show routing information and statistics for each ARX connected to the current switch. The output displays one table per host switch. Each table contains the following information:</p> <p><b>Hostname</b></p> <p>Status is “Current,” “Stale,” or “ERROR.” This represents the status of the peer’s <i>Link-State Advertisement (LSA)</i>. Peers exchange periodic LSAs with information about the tunnel state(s); this table expresses the latest LSA received from the Hostname.</p> <p>“Stale” indicates that the peer is unreachable, so at least one LSA was missed since the one shown.</p> <p>“ERROR” indicates that this peer has the same private subnet as another peer in the RON. This is an unsupported configuration. An ERROR message at the bottom of the output shows which peers have the conflict. Go to either switch’s CLI and use <a href="#">ip private subnet reassign</a> to change its subnet.</p> <p><b>Serial #</b> is the serial number for the peer’s latest LSA. This number increments whenever the switch receives a new LSA from this peer.</p> <p><b>Age</b> is the number of seconds since the last LSA was received from the remote peer.</p> <p><b>Private Subnet(s)</b> is the host’s private subnet. If the host is part of a redundant pair, this also shows the private subnet for the host’s peer.</p> <p>A sub table shows all tunnels configured for the host. Each tunnel appears in one row with the following information:</p> <p><b>Tunnel</b> is the name of the tunnel, set with the <a href="#">ron tunnel</a> command.</p> <p><b>Peer</b> is the host switch at the other end of the tunnel. You can change this with the <a href="#">cfg-if-vlan-ron-tnl peer address</a> command.</p> <p><b>State</b> is Down, Connecting, Connected, Shutdown, or Unknown. A new tunnel transitions from “Shutdown” to “Connecting” to “Connected.” “Down” indicates link failure: too many consecutive heartbeats were dropped (see <a href="#">heartbeat failure</a> and <a href="#">heartbeat interval</a>). “Shutdown” indicates that the tunnel was disabled with the <a href="#">shutdown (cfg-if-vlan-ron-tnl)</a> command.</p> <p><b>RTT(ms)</b> is the average Round-Trip Time (RTT) through the tunnel, in milliseconds.</p> <p><b>Loss(%)</b> is the percentage of packets lost in the tunnel.</p> <p><b>TCP (Kb/s)</b> is the estimated TCP throughput (in Kilobits per second) on the tunnel.</p> <p><b>Loss*RTT</b> is reserved for future use.</p> |

**Sample** prtIndA# show ron database  
displays the full RON database at the switch named “prtIndA.” See [Figure 14.3](#) on page 14-16 for sample output.

## show ron route

- Purpose** This command shows the IP-routing table used by the RON process.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator
- Syntax** `show ron route`
- Default(s)** None
- Guidelines** This shows a table of RON routes, one row per tunnel. Each row contains four fields:  
Destination is the host name of the peer switch at the other end of the tunnel.  
Subnet is the private-IP subnet of the peer switch.  
Via Tunnel is tunnel for sending packets to the Subnet.  
Milliseconds is average round-trip time, through the tunnel and back.
- Sample** `prtlnA> show ron route`  
displays the RON routing table. See [Figure 14.4](#) for sample output.
- Related Commands** [ron tunnel](#)

*Figure 14.4 Sample Output: show ron route*

# show ron tunnel

**Purpose** Use this command to display RON-tunnel configuration.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator

**Syntax** `show ron tunnel [name | redundancy | all]`

*name* (optional, 1-32 characters) identifies a particular RON tunnel to display. If you omit this, the command shows a summary of all RON tunnels.

*redundancy* (optional) is the name of an automatically-generated tunnel. This only appears on an ARX-1500 or ARX-2500 with a redundant peer. This tunnel carries redundancy-related traffic over the redundancy link that connects the redundant pair. The ARX creates this tunnel when you enter the `redundancy` command to join a redundant pair.

*all* shows details for all RON tunnels on the ARX.

**Default(s)** None.

**Guidelines** A Resilient Overlay Network (RON) connects multiple ARX devices. One RON tunnel connects two of them; use the `ron tunnel` command to create a RON tunnel. This command shows the configuration and state of RON tunnels.

**Guidelines: Summary Output** The `show ron tunnel` command (without a specific tunnel or the `all` keyword) shows a table of all RON tunnels. Each row summarizes the tunnel configuration and state:

**Name** is the tunnel name, set by the `ron tunnel` command.

**State** is Shutdown, Connecting, Connected, Unreachable, No Response, Mismatch, Error, or Unknown. A new tunnel transitions from “Shutdown” to “Connecting” to “Connected.” The error states are listed here.

- **Unreachable** means there is no local route to the tunnel’s remote endpoint. Use `ip route` to create a static route.
- **No response** indicates that the remote peer is not responding to standard RON packets (such as RON heartbeats), nor is it responding to lower-level ICMP pings. Either the network is down or the remote switch is down.
- **Mismatch** means that ICMP pings worked but the standard RON heartbeats did not. This implies the local configuration of the remote IP address is wrong (see `peer address`), or that the remote switch does not have a tunnel coming back to the local switch.

When the tunnel is first coming up, it is in this state between the time that the lower layers are connected and RON processes start. This is normal.

- **Shutdown** indicates that the tunnel was disabled with the `shutdown (cfg-if-vlan-ron-tnl)` command.
- **Error** should never appear. Contact F5 if you see this.

**Guidelines: Summary  
Output (Cont.)**

**Interface** shows the in-band management interface that serves as the local end of the tunnel (created with [interface vlan](#)).

**Remote Addr** is the IP address of the peer's end of the tunnel. Use the [peer address](#) command to change this. (The local address is the address of the tunnel's in-band management interface, set with [ip address \(cfg-if-vlan\)](#).)

**Up Time** is the amount of time that the RON tunnel has been "Connected."

**Guidelines: Detailed  
Output**

Include the interface name (or all) to display details for the tunnel(s):

**Name** is the tunnel name.

**Peer** is the host name of the remote peer.

**Tunnel State** is the same as **State** in the summary version.

**Uptime** shows how long the tunnel's state has been "Connected."

**Interface** shows the in-band management interface that serves as the local end of the tunnel (created with [interface vlan](#)).

**Remote Address** is the IP addresses at the other end of the tunnel. Use [peer address](#) to change the remote address.

**Security Policy** is reserved for future use.

**Ping Fail Limit** is the number of consecutive heartbeat failures to tolerate before declaring the **Tunnel State** "No response." Use [heartbeat failure](#) to change this threshold.

**Ping Interval** is the number of seconds between heartbeats. Use [heartbeat interval](#) to change it.

**Round Trip Time** is the average number of milliseconds for a packet to go through the tunnel and back.

**Packet Lost Rate** is the percentage of packets lost in the tunnel.

**TCP Throughput** is the tunnel's estimated throughput in bytes per second.

**Loss RTT Product** is reserved for future use.

**RON Packets In** and **RON Packets Out** counts the packets that are directly-related to RON, such as heartbeats and Link-State Advertisements (LSAs).

**Data Packets In** and **Data Packets Out** counts all other packets, including shadow-copy data.

**Data Bytes In** and **Data Bytes Out** is the total bytes (of Data Packets) exchanged.

**Local Processor** is the CPU where the tunnel terminates, in *slot.processor* format. Use [show processors](#) to see a list of all processors and their roles. This does not appear for the ARX-1500 or ARX-2500; all RON tunnels terminate at processor 1.1 on those platforms.

**Last Error Code** is 0 (zero), an error number, "Network Unreachable," or "Host Unreachable." If an error number appears here, contact F5 for interpretation.

**Control Errors** is the number of errors from RON control packets, such as RON heartbeats and LSAs.

**Data Errors** is the number of failed data packets. These are packets unrelated to RON control, such as replicated files.

- Samples** prtIndA> **show ron tunnel**  
displays a summary of all configured RON tunnels. See [Figure 14.5](#) for sample output.
- prtIndA> **show ron tunnel toBoston**  
displays details for a RON tunnel named, “toBoston.” See [Figure 14.6](#) on [page 14-21](#).
- prtIndA> **show ron tunnel all**  
displays details for all RON tunnels.
- stoweA> **show ron tunnel redundancy**  
displays details for the redundancy tunnel on an ARX-2500, “stoweA.” See [Figure 14.7](#) on [page 14-22](#).

Redundant Pairs (HA)

---

---

---

# clear counters redundancy

**Purpose** Use this command to clear the counters in the various `show redundancy ...` commands.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `clear counters redundancy [heartbeat | transition | network | critical-services]`

**heartbeat** (optional) clears only the heartbeat-related counters. This applies to heartbeats over the redundant-pair link (from [show redundancy peer](#)) as well as quorum-disk heartbeats (from [show redundancy quorum-disk](#)).

**transition** (optional) clears the counters associated with state/status transitions. This applies to all transition counters in all `show redundancy ...` commands.

**network** (optional) clears only the network counters, from the [show redundancy network](#) output. See [clear counters redundancy network](#) for details.

**critical-services** (optional) clears the counters associated with critical-services (from [show redundancy critical-services](#)).

**Default(s)** If you omit all of the optional flags, this clears all redundancy counters from all `show redundancy ...` commands.

**Platforms** any *except* ARX-VE

**Guidelines** These counters appear in the output of four show commands:

- [show redundancy peer](#),
- [show redundancy quorum-disk](#),
- [show redundancy network](#), and
- [show redundancy critical-services](#).

The first two of these commands have heartbeat counters that track the number of exchanged heartbeats. All of them have transition counters that track the number of times that the connection state has changed.

**Samples** `bstnA# clear counters redundancy`  
`bstnA#`

clears all counters.

`bstnA# clear counters redundancy heartbeat`  
`bstnA#`

clears only the heartbeat-related counters. This does *not* clear any transition-related counters.

`bstnA# clear counters redundancy transition`  
`bstnA#`

clears all transition-related counters from all `show redundancy ...` output.

**Related Commands** [show redundancy peer](#)  
[show redundancy quorum-disk](#)  
[show redundancy network](#)  
[show redundancy critical-services](#)

| <b>Guidelines</b>       | <p>The CLI prompts for confirmation if the route is down, the peer is down, or there is some other issue. Enter <b>yes</b> if you want to proceed anyway.</p> <p>You can re-issue this command multiple times to establish multiple critical routes.</p> <p>If a critical route fails on the current peer <i>and</i> the other peer has no failures, control fails over to the other peer. If the other peer has any failures that would ordinarily cause a failover (such as a major hardware fault), no failover occurs. This prevents unnecessary failovers.</p> <p>The ARX tests for failure with regular ARP requests. Every 20 seconds, the ARX sends an ARP to the route’s gateway. (The gateway is configured with the <a href="#">ip route</a> command.) If the gateway fails to respond, the ARX waits an additional 20 seconds before asking the peer if it is possible to fail over. The ARPs continue indefinitely at 20-second intervals. If the gateway responds before the failover is initiated, the failover does not occur.</p> <p>The ARX uses one of its in-band (VLAN) management addresses to send those ARP requests. The subnet you identify with this command must have a management address for its VLAN. Use the <a href="#">interface vlan</a> command to create an in-band management address for a the subnet’s VLAN.</p> <p>From gbl-ns-vol-shr mode, you can declare a namespace share as a critical resource with the <a href="#">critical</a> command.</p> <p>Critical routes (unlike critical shares) are <i>not</i> shared between redundant switches. This is because the switches may have different visibility into the network. To duplicate a critical route, issue this command on both peers.</p> <p>To show all critical routes and shares on the current peer, use the <a href="#">show redundancy critical-services</a> command.</p> |

**Samples**    `bstnA(cfg-redundancy)# critical route 172.16.54.0 255.255.255.0`  
designates a class-C subnet as a critical route. If the ARX loses all routes to that subnet *and* its redundant peer has no serious issues, a failover occurs.

`bstnA(cfg-redundancy)# no critical route 172.16.0.0 255.255.0.0`  
removes a class-B subnet from the list of critical subnets.

## enable (cfg-redundancy)

**Purpose** Use this command to enable redundant pairing on the current switch.

**Mode** cfg-redundancy

**Security Role(s)** network-engineer or crypto-officer

**Syntax** **enable**  
**no enable**

**Default(s)** None

**Platforms** any *except* ARX-VE

**Guidelines** Before you enable redundant pairing through [enable \(cfg-redundancy\)](#), you must complete the following steps:

1. For ARX-2000 or ARX-4000: Prepare interfaces or a channel to connect the switches.  
At both switches, define an interface that can be used in a redundant-pair link ([redundancy protocol](#)), or define a larger channel between the two switches ([redundancy protocol \(cfg-channel\)](#)).  
This is unnecessary for the ARX-500, which has a dedicated port for this link.
2. For ARX-500 only: configure a [ron tunnel](#) between the switches to carry the redundancy heartbeats.
3. At each switch, identify the redundant peer using the [peer](#) command.
4. Define the *quorum disk* by using the [quorum-disk](#) command on both switches. Each peer writes its heartbeats to the same external-filer share, called a quorum disk, and reads the heartbeats from its peer. The quorum disk configuration must be identical on both switches.

The **enable** command then starts the initial rendezvous of the switches. Once this command is invoked on the peer switch, the rendezvous can proceed. The pair is joined after the rendezvous is complete.

**Guidelines:** The **enable** command invokes the initial-rendezvous process, which then starts the metalog (namespace log) *resilvering* process. Metalog resilvering is duplicating the metalog data from the active peer to the backup peer. The metalog data must be mirrored on both peers to ensure that the namespace software can fail over. You may want to monitor the resilvering process if the peers are separated by a long distance: you can use the [show redundancy metalog](#) command for this. If resilvering times out due to excessive latency, you can use the [resilver-timeout](#) command to reset the timeout value.

**Guidelines:** The senior switch is elected based on its global configuration; if switch A has any namespaces or global servers and switch B does not, switch A becomes the senior switch. If neither has any namespaces or global servers, the one with the lower rendezvous address (established with the [peer](#) command) is elected senior. If both have namespaces and/or global servers, the rendezvous fails; see below.

**Guidelines: Failure  
Recovery**

One of the switches (if not both) should be devoid of any namespaces or global servers before you enable redundancy. If both have examples of these global-configuration objects, the rendezvous fails. Use the [show redundancy history](#) command to detect this failure. To recover, use the [clear global-config](#) command to remove all global-config from one of the peers and reboot it. Then enable redundancy again.

The rendezvous also fails if the private subnets of the peers match, or if one peer's private subnet matches any private subnet in the other's RON. The [show redundancy history](#) command indicates this problem if it occurs. To recover, use `no enable` to undo the redundancy configuration, use [ip private subnet reassign](#) on one of the switches, then try enabling redundancy again.

The switches continue to retry the rendezvous indefinitely. If you decide to abandon the pairing, you can use `no enable` to stop the switches from retrying. The `no enable` feature is disabled after the pair successfully forms.

**Sample**

```
prt1ndA(cfg-redundancy)# enable
enables redundant pairing on the current switch.
```

# nsm binary-core-files

**Purpose** By default, an NSM processor creates a detailed binary-core file if it has a failure. On the advice of F5 Support, you can use `no nsm binary-core-files` to return to the smaller ASCII form of NSM-core files.

The `nsm binary-core-files` command re-instates detailed core files from NSM processors. The core file is useful for diagnosing processor failures.

**Mode** `cfg`

**Security Role(s)** `crypto-officer`

**Syntax** `nsm binary-core-files`  
`no nsm binary-core-files`

**Default(s)** `nsm binary-core-files`

**Platforms** ARX-500, ARX-2000, and ARX-4000

**Guidelines** Only use this command on the advice of F5 Support.

An NSM processor requires very-little time to generate the smaller ASCII form of NSM-core files, but they offer less information for later diagnosis. An NSM processor requires up to three minutes to generate the detailed binary-core file, but it fails over to its peer processor at the beginning of the process. If two peer processors fail at the same time, the ARX fails over to its redundant peer before they write their core files. The extra time to write the binary-core file(s) has no effect on clients.

### ◆ Important

---

*A standalone ARX, without a redundant peer, loses service for up to three minutes if two peer processors fail at the same time. Without an ARX peer, clients must wait for the peer processors to write their binary-core files. For this reason and others, we recommend redundant ARXes at all live customer deployments.*

An ARX-500 requires [nsm recovery](#) before you can enable this feature.

Use the [show nsm](#) command to see the current setting for binary-core files.

**Sample** `bstnA(cfg)# nsm binary-core-files`  
sets the current chassis to produce detailed, binary-core files in the event of any NSM-processor failure.

|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                            | Each NSM-processor core has a redundant peer that takes over in case of a failure. A <i>recovered</i> processor goes into a “Standby” state while its peer processor manages all network traffic for both. If the peer processor fails, all network traffic fails back to the peer that failed first. On the advice of F5 Support, you can use <code>no nsm recovery</code> to prevent NSM-processor recoveries on this ARX.<br><br>The <code>nsm recovery</code> command re-enables this ARX’s NSM processors to recover from failures.                                                                                                                                                                                                                                                                                                               |

| <b>Purpose</b>          | An NSM-processor core can attempt to restart after a failure, without causing its entire NSM processor to reboot and go into a “Standby” state. Other cores on the same NSM processor are unaffected by this warm-restart of the failed core. Use the <code>nsm warm-restart</code> command to make NSM cores attempt these warm restarts.<br><br>The <code>no nsm warm-restart</code> command returns to the default: if any core fails on an NSM processor, the entire processor reboots.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Guidelines</b>       | <p>This command localizes the effects of an NSM-core failure. Only the core that failed restarts, without affecting any <i>sister cores</i> on the same processor.</p> <p>A warm restart produces a core-memory file, visible with the <code>show cores</code> command. The core-memory files produced by this failure are smaller than those produced by a full NSM restart, but they contain enough information for F5 Engineering to analyze the failure. The size of the core-memory file is unaffected by the <code>nsm binary-core-files</code> command.</p> <p>There are two internal counters, <i>restart count</i> and <i>restart limit</i>, that prevent repetitive warm restarts. The restart limit is 3, and the restart count applies to an entire NSM processor (or CPU). If core 1 fails on a four-core CPU, and then core 3 fails on the same CPU, the NSM CPU has a restart count of 2. If the restart count reaches the restart limit (3), the entire NSM CPU reboots and behaves as dictated by the <code>nsm recovery</code> setting.</p> <p>Each restart event times out after 24 hours, decrementing the restart count by one. For example,</p> <ul style="list-style-type: none"> <li>• At noon on Thursday, core 1 restarts - restart count = 1.</li> <li>• At 5PM on Thursday, core 3 restarts - restart count = 2.</li> <li>• At noon on Friday, core 1’s restart times out - restart count = 1.</li> <li>• At 5PM on Friday, core 3’s restart times out - restart count = 0.</li> </ul> <p>You can use the <code>show nsm</code> command to see the current settings for NSM warm restarts, NSM-processor recovery, NSM binary-core files. To see the history of warm restarts on this system, use the <code>show nsm warm-restart history</code> command.</p> <p>Hardware faults are too severe to allow for a warm restart. For hardware faults, the NSM processor fully reboots and restarts as set by the <code>nsm recovery</code> command.</p> |
| <b>Sample</b>           | <pre>bstnA(cfg)# nsm warm-restart</pre> <p>sets up the NSM-processor cores to independently restart on failure, without affecting any other cores on the same processor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## peer

**Purpose** At each redundant peer, use this command to identify the other switch.  
Use the `no` form of the command to remove the redundant-peer configuration.

**Mode** `cfg-redundancy`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `peer peer-address`  
`no peer`

*peer-address* (0.0.0.0-255.255.255.255) is one of the peer switch's management-IP addresses. This can be the out-of-band (MGMT) interface or one of the switch's inband (VLAN) management interfaces. For the ARX-1500 and ARX-2500, you must use the inband management interface defined for the redundancy link: define a special VLAN for the link (with `vlan` and `members (cfg-vlan)` for a standalone link, or with `vlan (cfg-channel)` for a channel), and use the `interface vlan` and `ip address (cfg-if-vlan)` commands to create the inband-management IP.

**Default(s)** Port default is 49800.

**Platforms** any *except* ARX-VE

**Guidelines** A *rendezvous* occurs after you issue `enable (cfg-redundancy)` at the second switch. Each switch uses its *peer-address* to contact the other switch and exchange information for the join operation. It also uses this address for regular heartbeat exchanges.

Define the redundant peer *before* issuing `enable (cfg-redundancy)` on the switches.

Use the `show redundancy peer` command to see the current configuration for the peer, as well as heartbeat counters.

**Sample** `bstnA(cfg-redundancy)# peer 10.1.1.12`  
identifies the switch at 10.1.1.12 as the current switch's redundant peer.

**Related Commands** `redundancy`  
`enable (cfg-redundancy)`  
`show redundancy peer`

## quorum-disk

**Purpose** Use this command to set up a quorum disk for a redundant pair.

**Mode** cfg-redundancy

**Security Role(s)** network-engineer or crypto-officer

**Syntax: NFS** `quorum-disk nfs-server:/export[path] {nfs2 | nfs3 | nfs3tcp}`

*nfs-server*:/*export*[*path*] (1-1024 characters) selects an NFS export:

*nfs-server* is the IP address for the filer (for example, 192.168.70.65). This address must be on a server (proxy-IP) subnet (see [ip proxy-address](#)) or reachable through a gateway on that subnet (via static route: see [ip route](#) to create a static route).

*export* is the path to an NFS export on the server.

*path* (optional) is the specific directory to use.

*nfs2* | *nfs3* | *nfs3tcp* is a required choice; this is the NFS protocol to use for accessing the quorum-disk share.

**Syntax: CIFS** `quorum-disk \\cifs-server\share[path] cifs [DOMAIN]/username spn spn`

\\*cifs-server*\*share*[*path*] (1-1024 characters) is the syntax for a CIFS share.

*cifs-server* is the IP address for the filer (for example, 192.168.23.23). This address must be reachable, as described above for an NFS filer.

*share* is the specific share to use.

*path* (optional) is a path within the share.

*cifs* is a required keyword.

[*DOMAIN*]/*username* (1-1024 characters) is the username that the redundancy software can use to write to the CIFS share. If you use a short *DOMAIN* name, like “medarch,” you authenticate with NTLM or NTLMv2. If you use an FQDN for the domain, like “medarch.org,” you use Kerberos authentication.

*spn spn* (required for a Windows 2008 cluster, optional for other servers; 1-255 characters) is the Service-Principal Name (SPN) for the back-end server. You require a SPN to connect to a CIFS service on any Windows 2008 cluster.

**Default(s)** *path* defaults to the top of the NFS export or CIFS share.

**Platforms** any *except* ARX-VE

**Guidelines** The quorum disk is an NFS or CIFS share on any reliable, external filer. Each peer records its heartbeat messages on the quorum disk, and reads the heartbeat messages from the other. This is another path for reading the peer’s heartbeats, in addition to the path through the redundant-pair link.

The quorum disk also records ballot information for senior-switch election (see [show redundancy ballots](#)).

---

**Guidelines: Filer/Share Requirements** Use a highly-available, high-performance filer for the quorum disk. Round trip data write times for 1 block of quorum-disk data must be below 1 second. Slow-performing filers may cause the redundancy state to fluctuate and could lead to unnecessary switch down time.

The quorum disk's volume must be capable of storing 1 MB of file data. Use a share that blocks until the data is written to disk; no caching should be enabled for the share.

If the quorum disk is an NFS export, it must be configured (at the filer) for *synchronous* writes. Use the 'sync' option. We also recommend that you specify the `no_wdelay` option. CIFS shares do not have this configuration issue; they perform synchronous writes on request.

**Guidelines: Filer Connectivity** Each peer uses one of its in-band (VLAN) management addresses to communicate with the quorum disk's filer. Use the `interface vlan` command to create an in-band management address for a particular VLAN. The switch can reach the quorum-disk filer through this interface if

- the filer is on the same VLAN as the management interface, or
- the filer is reachable through a static `ip route` that goes through a gateway on the same VLAN as the management interface.

**Guidelines: Command Usage** If you connect to a CIFS share, the CLI prompts for a password to use for accessing the filer. It prompts a second time to confirm the password. For both prompts, enter the password for the *username*.

Use the `show redundancy quorum-disk` command to view the current configuration for the quorum disk, as well as some counters.

**Samples** `bstnA(cfg-redundancy)# quorum-disk 172.16.4.98:/lhome/qdisk1 nfs3`  
configures an NFS quorum disk.

```
provB(cfg)# quorum-disk \\10.10.201.8\qd cifs BOSTONCIFS/juser spn
svca@BOSTONCIFS
Password: jpasswd
Confirm: jpasswd
configures a CIFS quorum disk.
```

**Related Commands** `redundancy`  
`show redundancy quorum-disk`

|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                      | Use this command to start configuring redundancy between two switches. If an ARX with a redundant peer experiences a catastrophic failure, all of its services fail over to its peer ARX.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Guidelines: Before You Begin</b> | <p>Before you configure redundancy, you must connect the two peers together with a redundancy link. You can use a single port for this, but we recommend two or more ports in a <a href="#">channel</a>.</p> <p>The ARX-1500 and ARX-2500 use layer-3 (IP) networking software for exchanging heartbeats and important metalog data between the peers, so they require layer-3 configuration for their redundancy link. Use these commands to set up a layer-3 connection:</p> <ul style="list-style-type: none"><li>• Establish a new VLAN for this link. This requires different CLI commands for a channel than it does for a stand-alone port:<ul style="list-style-type: none"><li>– For a <a href="#">channel</a>, use the <a href="#">vlan (cfg-channel)</a> command to assign the channel to the VLAN.</li><li>– For a single port, use the <a href="#">vlan</a> command to create a new VLAN, then use <a href="#">members (cfg-vlan)</a> to assign the single port to that VLAN.</li></ul></li><li>• Use the <a href="#">interface vlan</a> to create a management-IP interface on the VLAN; this puts you into <code>cfg-if-vlan</code> mode.<ul style="list-style-type: none"><li>– From <code>cfg-if-vlan</code> mode, use the <a href="#">ip address (cfg-if-vlan)</a> command to establish an in-band (VLAN) IP address. You later use this VLAN-management IP address to identify this ARX to its peer, as described below.</li><li>– From the same mode, use <a href="#">redundancy (cfg-if-vlan)</a> to designate the interface for exchanging metalog data and heartbeats.</li><li>– From the same mode, use <a href="#">no shutdown (cfg-if-vlan)</a> to enable the management interface.</li></ul></li></ul> <p>Other platforms use a layer-2 connection for their redundancy link. After cabling the peers together, you use the <a href="#">redundancy protocol</a> command on the link's interface to designate it for use as this link. If you use multiple links in a <a href="#">channel</a>, as recommended, you use the <a href="#">redundancy protocol (cfg-channel)</a> command instead.</p> |

**Guidelines** The `cfg redundancy` command brings you to `cfg-redundancy` mode, where you configure the parameters for creating a redundant pair. From this mode, you use the `peer` command to identify the redundant peer; for the ARX-1500 and ARX-2500, you must use the other peer's in-band (VLAN) IP address at the other end of the redundancy link. You also use `quorum-disk` to identify an external-filer share to be used as a quorum disk. Repeat these steps at the peer switch, which must have redundancy parameters that agree. Once the parameters match on both switches, you enable the redundant pair with `enable (cfg-redundancy)` at each peer.

The `enable` command invokes the initial-*rendezvous* process, which then starts the `metalog` (namespace log) *resilvering* process. `metalog` *resilvering* is duplicating the `metalog` data from the active peer to the backup peer. The `metalog` data must be mirrored on both peers to ensure that the namespace software can fail over. You may want to monitor the *resilvering* process if the peers are separated by a long distance: you can use the `show redundancy metalog` command for this. If *resilvering* times out due to excessive latency, you can use the `resilver-timeout` command to reset the timeout value.

For rare situations where network maintenance may cause unwanted failovers, you can use the `suspend-failover` command to suspend failovers for a short time. Use the no form of the command to lift the suspension when the maintenance is finished.

**Guidelines: ARX-1500 and ARX-2500 Redundancy**

The ARX-1500 and ARX-2500 store their `metalog` data on their internal disks, along with logs, software-release files, and other management data. Managed volumes write their `metalog` data as clients change the volume state; the `metalog` is used to restore the volume configuration in the event of a failure. The `metalog` is also copied to the redundant peer. The speed of many volume operations depends on fast `metalog` writes.

Some other system operations create a large number of writes to the internal disk, potentially slowing `metalog` writes. This can slow volume performance, even if it occurs on the backup peer. For example, the process of upgrading the software release is extremely disk intensive, and may cause a noticeable performance degradation. During an upgrade, you use

- the `copy` command (`copy ftp`, `copy {nfs|cifs}`, `copy scp`, or `copy tftp`) to copy a full release file to the disk, and
- the `boot system` command to unpack the release file on the disk.

You should perform such disk-intensive operations during off-peak hours on the ARX-1500 and ARX-2500. This is true whether you run the operations on the active peer or the backup.

**Guidelines: ARX-VE Redundancy**

The ARX-VE is a Virtual Appliance (VA, similar to a VM) that runs on a standard hypervisor, and uses the same redundancy mechanisms that are used in a VM cluster. If the ARX-VE's hypervisor host fails, an identical ARX-VE on a peer hypervisor resumes processing. This does not require any additional configuration on the ARX, so the `redundancy` command, `cfg-redundancy` mode, and other ARX-redundancy operations are excluded from the ARX-VE CLI.

**Sample** `bstnA(cfg)# redundancy`  
`bstnA(cfg-redundancy)# ...`  
 starts redundancy configuration.

|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use this command to resolve a rare scenario (described below) where one peer has failed unrecoverably and the other will not take over as the active peer. |
| <b>Mode</b>             | priv-exec                                                                                                                                                  |
| <b>Security Role(s)</b> | network-technician, network-engineer, or crypto-officer                                                                                                    |
| <b>Syntax</b>           | <b>redundancy force-active</b>                                                                                                                             |
| <b>Default(s)</b>       | None.                                                                                                                                                      |
| <b>Platforms</b>        | any <i>except</i> ARX-VE                                                                                                                                   |
| <b>Guidelines</b>       | This command forcibly promotes the backup peer to active status.                                                                                           |

## ◆ Important

---

*This command discards any forward progress made at the other peer. It also re-imports all namespaces, forcing all clients to re-mount all front-end services. Never use this command unless under the circumstances below, and with the advice of F5 personnel.*

Consider a redundant pair where Peer A is active and Peer B is either active or backup. Peer B fails, then (later) Peer A fails unrecoverably. When Peer B recovers, it refuses to take an active role because it knows that it was down while Peer A was active: Peer A may therefore have changed its configuration or managed some transactions with back-end filers. If Peer B were to take control, all such configuration changes and transactions would be lost. In this scenario, Peer B waits indefinitely for Peer A and the redundant pair never comes back online.

You need to force Peer B to take an active role, thus abandoning any configuration changes or transactions that occurred on Peer A. The peer switch must be offline, and the current switch must have been up and waiting for its peer to come online for at least 5 minutes. Also, the quorum disk must be online and available. Use the [show redundancy](#) command to verify that the peer is down and the quorum disk is connected.

The CLI warns you before discarding transactions and rebooting both peers. Enter **yes** to proceed.

## Sample

```
bstnA(cfg)# redundancy force-active
CAUTION: To avoid data corruption, the peer switch MUST BE OFFLINE and
remain offline while this command executes. Any global configuration
changes made on the Active peer switch while this switch was
unavailable will be lost. All namespaces will be re-imported
automatically to ensure consistency in the metadata. All in-flight
transactions not synchronized will be lost. NFS-based clients will
need to remount. Please contact Technical support for further advice.

Proceed? [yes/no] yes
bstnA(cfg)# ...
```

forces the “bstnA” switch to take active status in its redundant pair.

**Related Commands** [show redundancy](#)

---

# resilver-timeout

**Purpose** The redundant peers exchange their metalog (namespace-transaction) data during initial rendezvous, or after a failover. This is called *resilvering* the metalog data. At some sites, the latency between peers is high enough that the resilvering process times out before the pair can form. On the advice of F5 Support, you can use this command to increase the time allowed for resilvering.

Use the `no` form of the command to reset the resilvering timeout to its default.

**Mode** `cfg-redundancy`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `resilver-timeout minutes`  
`no resilver-timeout`

*minutes* (6-60) is the maximum number of minutes for resilvering. If this time expires before resilvering is complete, the redundant pair cannot form.

**Default(s)** 6 minutes

**Platforms** any *except* ARX-VE

**Guidelines** A *rendezvous* occurs after you issue `enable (cfg-redundancy)` at the second switch. A *failover* occurs whenever the active switch fails and the backup switch takes control. You can use this command to increase the time allotted for resilvering metalog data during a rendezvous or a failover.

The default is sufficient for most sites. Use this command only on the advice of F5 Support. It is unnecessary if you use a direct layer-2 connection for the redundancy link. The packet latency on a direct connection is typically very short.

If resilvering times out, the redundancy software retries until it succeeds. This severely impacts system performance. You can use the `show redundancy history` command to see the results of resilvering (referenced as “synchronization” in that output), and determine whether or not it is repetitively timing out. You can use `show redundancy metalog` to monitor the resilvering process as it occurs.

Use the `show redundancy resilver-timeout` command to see current timeout value for resilvering.

**Sample** `provA(cfg-redundancy)# resilver-timeout 10`  
sets the resilvering timeout to 10 minutes on the “provA” switch. The resilvering process has 10 minutes to complete after rendezvous or failover.

**Related Commands** `redundancy`  
`show redundancy resilver-timeout`  
`show redundancy metalog`

## show nsm

**Purpose** The `show nsm` command shows the current state of the NSM-maintenance features: processor recovery and binary-core files. For each of these features, this command shows the administrative setting as well as whether or not the setting is operational.

**Mode** (any)

**Security Role(s)** crypto-officer

**Syntax** `show nsm [recovery | binary-core-files | warm-restart]`

`recovery | binary-core-files | warm-restart` (optional) focuses the output on the state of a single NSM-maintenance feature. If you omit these, the output shows the state of all NSM features.

**Platforms** ARX-500, ARX-2000, and ARX-4000

**Guidelines** The output contains a separate table for each NSM-maintenance feature, **Recovery**, **Binary Core Files**, and **Warm-Restart**. Each table has one row per NSM, where each row has the following fields:

**Proc** identifies an NSM processor, in `slot.processor` format.

**Status - Admin** is the status that was last set for this feature.

**Status - Operational** is the feature's actual status.

You can use `[no] nsm recovery` to disable or re-enable NSM-processor recovery. You can also use `[no] nsm binary-core-files` to change NSM-processor core files to an ASCII format or a larger binary format. NSM recovery must be enabled before you can enable NSM binary-core files. Only change these settings on the advice of F5 Support. The final table concerns the `[no] nsm warm-restart` command; this allows a processor core to fail and recover independently, without rebooting the entire processor.

---

**Sample** bstnA# show nsm binary-core-files

Binary Core Files:

| Proc | Status  |             |
|------|---------|-------------|
|      | Admin   | Operational |
| 2.1  | Enabled | Enabled     |
| 2.2  | Enabled | Enabled     |
| 2.3  | Enabled | Enabled     |
| 2.4  | Enabled | Enabled     |
| 2.5  | Enabled | Enabled     |
| 2.6  | Enabled | Enabled     |
| 2.7  | Enabled | Enabled     |
| 2.8  | Enabled | Enabled     |
| 2.9  | Enabled | Enabled     |
| 2.10 | Enabled | Enabled     |
| 2.11 | Enabled | Enabled     |
| 2.12 | Enabled | Enabled     |

shows that the current chassis is configured to produce detailed, binary core files in the event of an NSM-processor failure.

[nsm binary-core-files](#)  
[nsm warm-restart](#)

## show nsm warm-restart history

**Purpose** To show the history of warm restarts by the NSM-processor cores, use the `show nsm warm-restart history` command.

**Mode** (any)

**Security Role(s)** crypto-officer

**Syntax** `show nsm warm-restart history [processor slot.processor]`

**processor slot.processor** (optional) specifies one NSM processor for which to view this history. If you omit this option, the output includes warm-restart history for all NSM processors.

*slot* (2 for ARX-4000; 1 for any other) is the slot number.

*processor* is the processor number. Use the [show processors](#) command to show all processors and their associated *slot.processor* IDs.

**Platforms** ARX-500, ARX-2000, and ARX-4000

**Guidelines** An NSM *warm restart* occurs when an NSM-processor core encounters a catastrophic software failure and reboots, without causing any other cores to reboot with it. A warm restart is only possible on a system where [nsm warm-restart](#) is enabled.

The output contains two tables, one that shows the most-recent recent warm restart and another that shows the current values for *restart count* and *restart limit*. The restart count is the sum of all restarts for a given CPU's cores, and the restart limit is the maximum number of restarts for each CPU. If a core fails after its CPU's restart count reaches the restart limit, the entire CPU reboots. The full-CPU reboot follows the rules set by the [nsm recovery](#) command.

The first table has one row per NSM processor, with the following fields:

**PROC** identifies the NSM processor, in *slot.processor* format. This identifies a specific core on the CPU.

**CPU** identifies the NSM-processor CPU, where each CPU typically contains multiple cores. This field identifies the CPUs with a letter, such as A, B, or C.

**Restart Number** is the most-recent restart number for this core. The full restart count for the CPU is the sum of all its cores' **Restart Numbers**. As mentioned above, you use the [nsm warm-restart](#) command to make warm restarts possible for NSM cores.

**Date/Time (UTC)** is time stamp (if any) for the most-recent warm restart.

The second table shows the number of restarts remaining for each hardware CPU from the first table:

**Slot** is the slot number for the NSM processor.

**CPU** identifies the NSM-processor CPU, where each CPU typically contains multiple cores. This maps to the **CPU** field in the table above.

**Restart Remaining** is the number of warm restarts remaining for this NSM CPU. This count decreases by one every time one of the CPU's cores has a warm restart. It increases by one every time a warm restart ages by 24 hours.

**Restart Limit** is the total number of restarts allowed for each CPU.

**Samples** bstnA# show nsm warm-restart history

shows the warm-restart history for all NSM processors in the “bstnA” chassis. See [Figure 15.1](#) for sample output., without any warm restarts.

## prtlnA# show nsm warm-restart history

shows the warm-restart history for all NSM processors in the “prtlnA” chassis. See [15.2, on page 15-26](#) for sample output., where two warm restarts occurred in the last 24 hours.

| <b>Guidelines</b>       | <p>Node is 1 for the initial-senior switch, 2 for the initial-junior switch, or QD for the quorum disk. The asterisk (*) indicates the local node.</p> <p>Switch/Quorum Disk identifies each node with a hostname or IP address.</p> <p>Status is Up, “Up,NoFovr,” Down, Suspended, or Unknown for a redundant peer. The “UpNoFovr” status indicates that someone used <a href="#">suspend-failover</a> to temporarily freeze the Active/Backup status of the peers and suspend failovers.</p> <p>The status is Up, “Up,NoHb,” Pending, or Down for the quorum disk. “Up,NoHb” means that the quorum disk is up but not showing any heartbeats from the peer yet.</p> <p>Role is Active, Backup, or Quorum. The senior peer is always Active, meaning it can run namespace software and virtual servers. The junior peer is “Backup;” it is a hot standby for the active peer.</p> <p>Transitions: Total is the number of times that the Status has changed. This increments for each failover. If there has never been a failover, the Total is “Never.”</p> <p>Transitions: Last (UTC) is the timestamp for the last status change, in Universal Coordinated Time (UTC).</p> |
| <b>Sample</b>           | See the sample output in <a href="#">Figure 15.3</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## show redundancy all

- Purpose** Use this command to show all redundant-pair information with a single command.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show redundancy all`
- Default(s)** None
- Platforms** any *except* ARX-VE
- Guidelines** This command shows all flavors of `show redundancy ...` output, in the following order:
1. [show redundancy](#)
  2. [show redundancy history](#)
  3. [show redundancy peer](#)
  4. [show redundancy ballots](#)
  5. [show redundancy network](#)
  6. [show redundancy critical-services](#)
  7. [show redundancy resilver-timeout](#)
  8. [show redundancy quorum-disk](#)
- For details about the `show redundancy all` output, refer to the command descriptions for these individual commands.
- Sample** See the sample output in [Figure 15.4](#).
- Related Commands** [redundancy](#)

### Heartbeat latency summary:

```
0-499msec : 100.00%
500-999 msec : 0.00%
1000-3999 msec : 0.00%
No response : 0.00%
```

# show redundancy ballots

**Purpose** Each failover is followed by an election process to choose the senior switch. Use this command to show the ballots from the most-recent redundancy election.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** **show redundancy ballots**

**Default(s)** None

**Platforms** any *except* ARX-VE

**Guidelines** Node is 1 for the initial-senior switch, 2 for the initial-junior switch, or QD for the quorum disk. The asterisk (\*) indicates the local node.

Switch/Quorum Disk identifies each peer with a hostname or IP address.

Ballot Cast shows the most-recent seniority vote from each node:

Senior Switch is the switch that the node believes should be senior, and

Epoch is the epoch number that the node last recorded. All three quorum members keep a common epoch number that increments with each failover. If one node has a lower epoch number than the others, its vote for Senior Switch is discounted.

**Guidelines: Redundancy Elections** Each switch, as well as the quorum disk, stores an epoch number and the identity of the senior switch. After a switch failure, this information is exchanged as election *ballots* to determine which peer should have seniority. Ballots with higher epoch numbers carry more weight in the election. If two nodes agree but disagree with the third, the majority rules. The results determine which peer is senior.

None of the ballots are authoritative; use the [show redundancy](#) command to see which peer(s) is/are currently active. (The senior switch is always active, the junior switch is active after the initial rendezvous but backup after a failover.)

For example, the following table shows that the Quorum Disk and the second peer, “prtlndB,” agree on the Epoch number (9) and the senior peer (node 2, which is prtlndB). The “prtlnDA” peer cast the dissenting vote (1, or itself, as senior) with a lower Epoch number (8). From this output, we can infer that “prtlnDA” was senior before it failed, then became junior when it rejoined the pair.

```

...
 Ballot Cast
Node Switch/Quorum Disk Senior Switch Epoch

*1 prtlnDA 1 8
 2 prtlndB 2 9
QD 192.168.74.83 2 9
...

```

Ballots are only cast when a node fails, so all ballots are 0 (zero) when the pair first forms. In this case, both nodes are always active and Node 1 is always senior.

**Sample** See the sample output in [Figure 15.5](#).

| <b>Purpose</b>                        | If the current switch loses contact with a critical service (such as a critical namespace share or a critical subnet), a failover may occur. Use this command to show all of the critical services configured for the current peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Guidelines</b>                     | <p>Each critical service has one row in the table:</p> <p><b>Type</b> is “quorum” “share,” “route,” or “meta-only.” The quorum disk is a critical resource by default, and you cannot remove it from this list. To declare a namespace share as “critical,” use <a href="#">critical</a> in gbl-ns-vol-shr mode. To create a critical route, use <a href="#">critical route</a> in cfg-redundancy mode. A “meta-only” resource is a dedicated metadata share that is critical: use <a href="#">metadata share</a> to configure a dedicated metadata share, and use <a href="#">metadata critical</a> to make it a critical resource.</p> <p><b>Service</b> specifies the exact route or share. For a quorum disk, this shows the machine and path to the share. For shares, this shows the share in <i>namespace~volume~share-name</i> format. For a critical route, this shows the critical subnet in <i>ip-address/subnet-length</i> (CIDR) format.</p> <p><b>Status</b> is “Up,” “Down,” or “Config.” A “Config” status indicates that the critical service is configured but the Up or Down status has not been determined yet.</p> <p><b>Transitions: Count</b> is the number of times that the <b>Status</b> has changed.</p> <p><b>Transitions: Last (UTC)</b> is the timestamp for the last status change, in Universal Coordinated Time (UTC). If there has never been a failover, this shows “Never.”</p> <p><b>Counters Last Cleared</b> is the timestamp for the last time someone ran <a href="#">clear counters redundancy [critical-services]</a>.</p> |
| <b>Guidelines: Failover Algorithm</b> | <p>Only an active switch can initiate a critical-services failover. By default, both switches are active. After a failover, only the senior switch is active.</p> <p>If an active switch loses a critical share or route, it requests a failover. If the peer has all critical routes, shares, and access to the quorum disk, the failover occurs. Conversely, the peer rejects the failover if it has lost any of its own critical resources: a failover in this case could cause more service outages than it resolves.</p> <p>Note the difference in the way that the quorum disk is treated. Peer A does not initiate a failover if it loses access to the quorum disk. If peer A loses some other critical service (such as a critical share), it does initiate a failover. In this case, peer B <i>rejects</i> the failover if peer B cannot access the quorum disk. Loss of the quorum disk can prevent a failover, but never causes a failover.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Both peers in a redundant pair require the same license, to prevent any loss of service after a failover. A failover to a peer with a lesser license would result in fewer supported features and fewer available system resources. To confirm that the licenses are the same between the current peers, use the <code>show redundancy license</code> command.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Mode</b>             | (any)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Platforms</b>        | any <i>except</i> ARX-VE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Guidelines</b>       | <p>The output contains a success message if the licenses are the same for both peers. Otherwise, it returns a failure message along with all mis-matched features.</p> <p>In the case of a failure, you need to determine which peer has the desired license, and then activate or re-activate the license at the other peer. Run <a href="#">show active-license</a> at each peer to see details about the licenses there. If the peer can connect to the Internet, you can use the <a href="#">license activate</a> command to automatically activate the license there. Otherwise, you can use a manual activation method, as described in the documentation for the <a href="#">license create license-dossier</a> command.</p> |
| <b>Sample</b>           | <pre>prt1ndA&gt; show redundancy license % INFO: The HA peer license is equivalent to the license on this ARX.</pre> <p>shows that the licenses match between the peers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

# show redundancy metalog

**Purpose** Metalog (namespace transaction) data is mirrored between redundant peers during their initial rendezvous, and it is duplicated between the peers during normal operation. The duplication process is called *resilvering*. You can use the `show redundancy metalog` command to see the current state of the metalog-resilvering process between peers. This command is especially useful for monitoring the connection between redundant peers that are separated by long distances.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show redundancy metalog`

**Default(s)** None

**Platforms** any *except* ARX-VE

**Guidelines** The active peer's metalog data must be mirrored at the backup peer so that namespace software can recover after a failover. Use this command to monitor the resilvering process.

This command only functions on the active peer.

Use this output to gauge the latency and performance of the redundant-pair link. An overly-long latency between peers can cause a large number of metalog-packet retransmits (see below), and may lead to slow responses that are noticeable to [namespace/volume](#)/front-end service clients.

On all platforms, the namespace software keeps metalog read/write statistics. You can use the [show statistics metalog](#) command to see these metalog-usage statistics from a namespace-software perspective.

The ARX-1500 and ARX-2500 store their metalog data on their internal disks. On those platforms, you can use the [show metalog usage](#) command to see the metalog-usage statistics.

The ARX-VE stores its metalog data on an external data store. On the ARX-VE, you can use the [probe metalog latency](#) command to test the latency between the ARX and this external storage.

**Guidelines: Output** The output shows the current state of the resilvering process:

State is

- **Resilvering** - the active peer is copying all of its metalog data to the backup peer during a rendezvous.
- **Peer Online** - the metalog data was 100% duplicated after rendezvous, and now the active peer is sending metalog updates as they occur.
- **Peer Offline**

The next three fields only appear for the **Resilvering** state, which occurs during rendezvous:

**Started** is the start time for the rendezvous process.

**Timeout** indicates the total time allowed for resilvering. The resilvering process times out, sends an SNMP trap, and restarts if it exceeds this time limit. You can use the [resilver-timeout](#) command to reset this time limit.

**Time Remaining** is the estimated time left for resilvering. This estimate is based on the current data-transfer rate and the amount of data left to transfer.

**Byte Count** is the number of bytes of metalog data transferred to the backup peer. If the initial Resilvering process is still underway, this also shows the total size of the metalog data to be copied to the backup peer.

**Retransmits** counts the retransmissions of individual metalog packets. A retransmit occurs if an internal timeout passes before the packet is acknowledged by the backup peer. This field counts the total retransmits that occurred since the most recent start of the resilvering operation. A long latency between peers may increase the number of retransmits. This always displays 0 (zero) for the ARX-1500 or ARX-2500 when they are resilvering. These platforms use a different transmission mechanism for their metalog packet.

**Latency** shows the minimum, maximum, and average latency for sending packets of metalog data to the backup peer. These are measured in micro-seconds (us).

**Data Rate** shows the average megabits per second for the transfer of metalog data. This field only appears while resilvering is occurring.

```
Samples nyc15> show redundancy metalog
State: Resilvering

Started: 01/31/2012 22:48:03 +0000
Timeout: 00:06:00 sec
Time Remaining: 00:00:58 sec

Byte Count: 992 M of 3.7 G (26%)

Retransmits: 0

Latency:
 Min: 18538 usec
 Max: 77860 usec
 Avg: 22715 usec

Data Rate: 47.2 Mb/s
```

shows the state of metalog resilvering on the “nyc15” chassis.

```
prtlnA> show redundancy metalog
State: Peer Online

Byte Count: 55 M
Retransmits: 0

Latency:
 Min: 80 usec
 Max: 127 usec
 Avg: 83 usec
```

shows the state of metalog resilvering on the “prtlnA” chassis. In this case, the initial resilvering is complete and the active peer is sending metalog updates as it generates them.

Transitions
 Count: 1
 Last: 05:33:19 09/14/2009
 Reason: Peer switch 'prtlnDB' is now online
```

---

# show redundancy quorum-disk

**Purpose** A quorum disk is a filer share that each switch uses to write its own heartbeats and read the heartbeats from its peer. Use this command to show the configuration and counters associated with the quorum disk.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show redundancy quorum-disk`

**Default(s)** None

**Platforms** any *except* ARX-VE

**Guidelines** Path is in *machine:path* format (for an NFS export) or *\machine\path* format (for a CIFS share). This is the external-filer share used as the quorum disk. From `cfg-redundancy` mode, use `quorum-disk` to reset this.

**Protocol** is the file-access protocol (`nfs2`, `nfs3`, `nfs3tcp`, or `cifs`) used to access the quorum-disk share. This flag is also set with the `quorum-disk` command.

If the protocol is `cifs`, the following fields appear to describe the CIFS options used to access the quorum disk. These are all options from the `quorum-disk` command:

**QD User** is the Windows username that the ARX uses as its identity when accessing the quorum disk.

**User Domain** is the Windows domain for the above username.

**QD SPN** is the Service Principle Name (SPN) for the quorum disk's host server.

**Status** is Up, Pending, or Down. Pending indicates that the quorum disk is functional but the redundant pair is in the process of forming.

**Heartbeats** are counters for the number of redundancy heartbeats sent to the quorum disk by the current node, and received from the quorum disk by the current node. You can use the `clear counters redundancy` command to clear this counter.

**Transitions** shows the changes in Status for the quorum disk:

**Count** is the number of changes. This should be a low number; the only valid reason for a quorum-disk transition is a planned outage of the quorum-disk filer (such as a hardware upgrade).

**Last** is the time stamp for the most-recent transition.

**Reason** is the log message associated with the Status change.

You can use the `clear counters redundancy` command to clear the transitions counter, too.

**Guidelines (Cont.)** Heartbeat Latency is a chart of latency measures over the past 24 hours. This is the latency (round-trip time) for heartbeat packets between the current peer and the quorum disk. Each row shows the latency measures in one hour:

- Time Interval shows the start and end time for the hour, in local time.
- [0-499] is a count of heartbeats with a latency of 0-499 milliseconds. This column should have by far the highest count of all of them.
- [500-999] is the number of heartbeats that took 500-999 milliseconds to make a round trip. This is a long latency and should be uncommon.
- [1-3999] shows how many heartbeats took 1 second to 3,999 milliseconds (almost 4 seconds). This latency should be extremely rare, if it ever occurs.
- [No Response] is the number of heartbeats that were lost. This number should be 0, unless there is a planned outage for the quorum disk. If either peer reboots while one of them is disconnected from the quorum disk, they both may reboot simultaneously.

Heartbeat Latency Summary shows the percentage of heartbeats in each of the above time intervals.

If the Heartbeat Latency and Heartbeat Latency Summary tables indicate long latencies, choose a faster quorum disk. You can run the [quorum-disk](#) command on both peers to change the quorum disk.

**Sample** See the sample output in [Figure 15.9](#).

Time of reboot: Tue Mar 2 07:31:39 2010

Message: software reboot: Dual reboot request was issued
```

---

## show redundancy resilver-timeout

**Purpose** Initial rendezvous and standard managed-volume processing involves duplicating the metalog (namespace transaction) data from the active peer to the backup. This process is called *resilvering*. Use this command to show the maximum time allowed for resilvering. If this time expires before resilvering is complete, the redundant pair cannot form.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show redundancy resilver-timeout`

**Default(s)** None

**Platforms** any *except* ARX-VE

**Guidelines** The output is a single value, the timeout allowed for resilvering. You can use the [resilver-timeout](#) command to reset this. The [show redundancy metalog](#) command shows the current state of the resilvering process.

**Sample** `prt1ndA# show redundancy resilver-timeout`

```
Resilver Timeout: 6 minutes
```

**Related Commands** [resilver-timeout](#)  
[redundancy](#)  
[show redundancy](#)  
[show redundancy metalog](#)

## suspend-failover

**Purpose** There are occasions when site maintenance may inadvertently cause redundancy-inspired failovers and reboots. These can complicate the maintenance procedure. You can use the `suspend-failover` command to prevent any failovers until further notice.

You can later lift the suspension with `no suspend-failover`.

**Mode** `cfg-redundancy`

**Security Role(s)** `network-engineer` or `crypto-officer`

**Syntax** `suspend-failover`  
`no suspend-failover [force]`

**force** (optional) is only necessary when the peer switch is disabled or otherwise unreachable. This causes the current switch to assume the active role in the pair, whether or not it previously had the active role. This is similar to the behavior from the `redundancy force-active` command.

### ◆ Important

---

*If you use the `force` option on the backup peer when the other peer is still active and connected, this command creates a “split-brain” condition.*

**Default(s)** `no suspend-failover`

**Platforms** any *except* ARX-VE

**Guidelines** Use this command only under the guidance of F5 personnel.

This command locks the redundancy state until the suspension is lifted. The peers retain their active and backup roles during the suspension. The CLI prompts for confirmation before doing this; enter **yes** to proceed.

You can only use this command when redundancy is enabled, the peer is reachable and ready to take control, the quorum disk is functioning normally, and all critical services are healthy on the active peer. Use the `show redundancy` command to verify that the peer and quorum disk are functioning, and use `show redundancy critical-services` to check on critical services.

During a period of failover suspension, both peers continue to record conditions that would typically cause failovers and/or failover-related reboots. These appear in the syslog (use `show logs syslog` to view the syslog), and some result in SNMP traps (see the [ARX SNMP Reference](#) for a full list of traps). Traps and logs also appear for any suppressed failovers or reboots.

---

**Guidelines: Force Option** As stated above, you should only use the **force** option if the peer is disabled or otherwise unreachable. If the peer is reachable and active, the **force** option may cause both peers to take the active role and work at cross purposes. This is called a “split-brain” situation, and it can create serious issues that are very difficult to repair. The CLI prompts for special confirmation before lifting suspension in this way.

A switch that is properly forced can successfully re-join its peer later, but there is another possibility of “split brain” during that rendezvous. The rendezvous happens automatically when you first boot the repaired peer. A “split-brain” may occur if the running switch has any connectivity issues during the rendezvous. Verify that the running switch has full network connectivity and all of its critical resources, especially the quorum-disk link, before booting its repaired peer.

**Samples** prt1ndA(cfg-redundancy)# **suspend-failover**

Are you sure you want to suspend redundancy? [yes/no] **yes**  
suspends failovers and failover-related reboots on “prt1ndA” and its redundant peer.

bstnA(cfg-redundancy)# **no suspend-failover**

lifts the failover suspension from “bstnA” and its redundant peer.

bstnA(cfg-redundancy)# **no suspend-failover force**

The force option should only be used when the peer switch is disabled. The peer should be off or isolated from the network. Otherwise, services could be severely disrupted.

Are you sure you want to proceed? [yes/no] **yes**  
forces a resumption of standard-redundancy. This should only be used if the redundant peer is offline.

**Related Commands** [show redundancy](#)  
[show redundancy critical-services](#)

---

## Active Directory Discovery

---

---

---

## active-directory update seed-domain

**Purpose** The ARX must understand the Active-Directory (AD) hierarchy in the Windows network. That is, each ARX-CIFS service (and, in some sites, the authentication software for the CLI/GUI) must know where to find the correct DC for each domain in the AD forest. The ARX database requires a full representation of the AD forest, with the IP addresses of at least one DC per domain.

Use the `active-directory update seed-domain` command to discover an AD forest in your network and add its representation to the ARX.

**Mode** priv-exec

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `active-directory update seed-domain seed proxy-user proxy [domain-controllers max-dcs] [site-name site] [verbose] [tentative]`

*seed* (1-255 characters) is the name of one domain in the forest. The ARX uses this domain name to begin its forest discovery. This becomes the name of the AD-forest in the ARX configuration.

*proxy* (1-32 characters) is a [proxy-user](#) with credentials for accessing the seed domain's DC(s). These credentials can belong to the seed domain itself, or any domain that is trusted by the seed domain. The ARX queries the DC for the names of other domains in the same AD forest.

*max-dcs* (optional, 1-100) sets a maximum number of DCs used in each domain. The ARX queries its DNS server to discover all the DCs in each domain; if the DNS server returns more DCs than *max-dcs*, the ARX takes the top DCs from the DNS list. The ARX uses the order returned from DNS.

*site* (optional, 1-64 characters) identifies the AD site for the ARX. If it knows of multiple DCs that can answer the same query, the ARX prefers DCs in its own site (if there are any) over DCs in any other site. The site name is defined on a DC with the [Active Directory Sites and Services](#) plugin. The site name is case insensitive, so "boston" and "BOSTON" are equivalent. If you omit this, the ARX software uses the AD site configured for the [ip proxy-address](#) subnet. Use this option if the AD's site configuration does not include the proxy-IP subnet.

*verbose* (optional) causes the command to show the results of the forest discovery as it progresses.

*tentative* (optional) makes the ARX perform the AD-forest discovery without creating the actual [active-directory-forest](#) configuration.

**Default(s)** *max-dcs* - all DCs returned from each DNS query.

*site* - the AD site configured on the external Active Directory for the proxy-IP subnet. This default requires that the proxy-IP subnet is defined in the AD; you can add the subnet on a DC with the [Active Directory Sites and Services](#) plugin.

**Guidelines** The ARX uses a DNS query to find the DC(s) in this domain, then queries one of the DCs for the other domains in the forest. The DNS server that you use must be able to translate for all DCs in the target forest. Use the [ip name-server](#) command to add a DNS server to the ARX configuration.

The [active-directory update seed-domain](#) command automatically discovers an Active Directory (AD) forest and adds it to the ARX configuration. The switch uses this information to support CIFS authentications in single- and multi-domain environments. After a successful discovery, the ARX configuration contains an AD-forest object with the name of the *seed* domain that you provided.

This creates a report named “active-directory-*seed\_domain*.rpt,” where *seed\_domain* is the seed domain that you chose in the command. The CLI displays the name of the report after you issue the command. Use [show reports type AdUp](#) to list all AD-discovery reports. To follow the progress of the AD-discovery operation, you can use [tail reports report-name](#) follow. Use [show reports report-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the [copy](#) or [delete](#) commands. If you want to truncate the report before it finishes, use the [truncate-report](#) command. See [Figure 16.1 on page 16-6](#) for a sample report.

Use the [show active-directory](#) command to show the configuration of the AD forest, as recorded on the ARX. To see the status of all DCs in the forest, use the [show active-directory status](#) command.

**Guidelines: Manual AD-Forest Configuration** As an alternative to this automatic-discovery process, you can use the [active-directory-forest](#) command to manually create or edit the AD-forest configuration. The [active-directory-forest](#) command brings you to gbl-forest mode, where you can add all types of domains and DCs in the forest. Typically, this is only used to add dynamic-DNS servers, described later.

**Guidelines: Domain Types** The report and the show commands all identify a domain type for each of the forest’s domains. The discovery process categorizes all of the domains as it finds them.

Domains in an AD forest have parent-child relationships based on their names. For example, the domain, “myco.com,” can have child domains named “usa.myco.com” and “britain.myco.com.” In this relationship, “myco.com” is called the *forest-root* domain and the other two domains are *child domains*.

An AD forest can also support trees that are outside the forest root’s tree. These are domains with two-way-transitive-trust relationships with one or more domains in the root tree, but their domain names are entirely different. They are called *tree domains*. To continue the above example, a tree domain named “nonprofit.org” may also be in the AD forest, and it may have a child domain named “euro.nonprofit.org.”

**Guidelines: Dynamic DNS** Kerberos authentication requires that the forest’s DNS servers have up-to-date mappings of the ARX’s CIFS services and their IP addresses. To facilitate DNS updates as the ARX’s CIFS services are added and removed, you can use the gbl-forest [name-server](#) command to identify a dynamic-DNS server for each domain in the forest. The discovery process does not discover dynamic-DNS servers.

In many cases, the DC itself can also double as the name server for its domain.

**Guidelines: Trusts Between Forests** For AD forests with two-way-trust relationships, where clients from one forest are allowed to access CIFS services from the other forest, you can use the [kerberos auto-realm-traversal](#) command to automatically discover all such trust relationships. Alternatively, you can use the [active-directory forest-trust](#) command to declare a forest-to-forest trust relationship in the ARX configuration.

**Guidelines: Offline DCs Slow the Discovery** If any of the discovered DCs are offline or unreachable, they slow the time required to discover the forest. Testing has shown that the forest discovery requires an additional 2.5 minutes for each offline DC; the delay may vary at your site.

**Samples** bstnA# active-directory update seed-domain ny.com proxy-user ny\_admin

Report File : active-directory-NY.COM.rpt

discovers an AD forest named "NY.COM" and adds the forest to the ARX configuration. This also creates a report, active-directory-NY.COM.rpt. See [Figure 16.1 on page 16-6](#) for a sample report.

bstnA# active-directory update seed-domain vt.com proxy-user ny\_admin verbose

Report File : active-directory-vt.com.rpt

DNS lookup vt.com from 172.16.108.139  
 10.51.100.8

## description (gbl-proxy-user)

**Purpose** Use the optional `description` command to set a descriptive string for the current proxy user. This appears in the `show proxy-user` command.  
Use the `no` form of the command to delete the description.

**Modes** gbl-proxy-user

**Security Role(s)** crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-255 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** `no description`

**Guidelines** This description appears in the output for [show global-config](#) and [show proxy-user](#).

**Sample** `stoweA(gbl-proxy-user[jckilley])# description "Jean-Claude's user identity"`  
specifies a description for the current proxy-user configuration.

**Related Commands** [show proxy-user](#)  
[show global-config](#)

---

## proxy-user

**Purpose** Use this command to provide the ARX software with Windows credentials, so that it can perform the following functions:

- Query the Windows Active Directory for its Windows Domains and domain-controller (DC) addresses (see [active-directory update seed-domain](#));
- Validate inventory of back-end filers and import them into a managed volume;
- Maintain access control and permissions on back-end filers;
- Monitor free disk space on back-end filers;
- Enforce CIFS policy rules by migrating files between back-end shares.

You can also use a proxy user for other functions, such as logging into a filer's CLI and invoking snapshot operations. For these uses, the credentials may be a Unix username and password with permission to run snapshot commands.

Use the `no` form of the command to remove a proxy-user configuration.

**Mode** gbl

**Security Role(s)** crypto-officer

**Syntax** `proxy-user name`  
`no proxy-user`

*name* (1-32 characters) is a name you choose for the proxy user.

**Default(s)** None

**Guidelines** All CIFS namespaces require a proxy user, whether the network uses NTLM, NTLMv2, or Kerberos.

The switch uses a proxy-user configuration as its identity when it accesses back-end filers. This command places you in `gbl-proxy-user` mode, where you then use [user \(gbl-proxy-user\)](#) and [windows-domain \(gbl-proxy-user\)](#) to define a valid Windows username, password, and Windows domain for this proxy-user configuration.

The documentation for the [user \(gbl-proxy-user\)](#) command describes the exact privileges required for the Windows-user account. You can use the [probe exports](#) command with this proxy user to determine whether or not the proxy user has (at least) Backup Operator privileges. To prove that the proxy user has full Administrator privileges, use it with the [show exports ... paths](#) command; the paths are blank unless the proxy user belongs to the Administrators group on the filer.

After you create proxy-user configurations, you apply one or more to a namespace through the [proxy-user \(gbl-ns\)](#) command. Use the [show proxy-user](#) command to display all configured proxy users and their associated domains and usernames.

**Guidelines: Changing the Password**

For security reasons, you may choose to change the password for the proxy-user account from time to time. For a Windows proxy user, this change must occur in two places: the Active Directory, where the corresponding Windows user is defined, and in the ARX configuration. Use the following steps to make the change:

- Change the password on a Domain Controller (DC).
- Wait for all of the DCs in the proxy user's Windows Domain to synchronize their databases.
- After the DCs are synchronized with the new password, re-run the `user (gbl-proxy-user)` command to change the password on the ARX.

During the time that the proxy-user password on the ARX does not match the one in the external Active Directory, the volumes that use the proxy user cannot access any of their back-end-CIFS storage. This prevents the managed volumes from performing autonomous operations, such as policy-driven migrations, and causes the CIFS shares to go "offline." We recommend that you perform this procedure during non-busy hours.

**Sample**

```
bstnA(gbl)# proxy-user acoProxy2
bstnA(gbl-proxy-user[acoProxy2])#
 starts the configuration of proxy user, "acoProxy2."
```

**Related Commands**

```
user (gbl-proxy-user)
windows-domain (gbl-proxy-user)
description (gbl-proxy-user)
proxy-user (gbl-ns)
show global-config namespace
show proxy-user
probe exports
show exports ... paths
```

---

# show active-directory

**Purpose** To support CIFS authentication, the ARX requires an accurate representation of your network's current Active Directory (AD) forest(s). Use the `show active-directory` command to review the AD-forest configuration as currently recorded on the ARX.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show active-directory`  
`show active-directory forest forest-name`  
`show active-directory domain domain-name`

*forest-name* (optional, 1-256 characters) identifies a particular forest to show.

*domain-name* (optional, 1-256 characters) identifies a particular domain.

**Guidelines** For the current status of the DCs in this output, use the [show active-directory status](#) command.

The `show active-directory` command displays the current AD configuration in one or two sections: Active Directory Domains and, if there are any forest-to-forest trusts, an additional Forest Trust table.

**Guidelines: Active Directory Domains Output** The Active Directory Domains section contains one table per AD forest. Each table has a Forest Name heading, showing the name configured with the [active-directory-forest](#) or [active-directory update seed-domain](#) command. The forest table contains one sub table per domain. Each sub table row contains the following fields:

`forest-root`, `child-domain`, or `tree-domain` is the type of the Windows domain in the AD forest, followed by the domain name and its pre-Windows 2000 name.

This is the heading for the sub table of DCs for the domain. This domain name is discovered automatically, or it is manually set with the [forest-root](#), [child-domain](#), or [tree-domain](#) commands.

IP Address is the address of the Key-Distribution Center (KDC, a domain controller used for Kerberos) and/or dynamic-DNS server for this Windows domain. You establish this with the [forest-root](#), [child-domain](#), or [tree-domain](#) command, or the ARX automatically discovers it if you use [active-directory update seed-domain](#). You can also use [name-server](#) to identify a dynamic-DNS server; in many cases, dynamic DNS runs on the same server as the KDC.

Services are KDC and/or DNS, as explained above.

Preferred shows whether or not this DC is on the "preferred" list for its domain. The choices are "YES" or "NO." The Kerberos software chooses its active DC(s) from the preferred list if there are any online. The preferred DCs are the DCs in the same AD site as the ARX (see [active-directory update seed-domain](#) or [active-directory update forest](#)), or you can manually set the DC preference with an optional flag in the [forest-root](#), [child-domain](#), or [tree-domain](#) commands.

**Guidelines: Forest Trust Table**

The Forest Trust table only appears if at least one forest-to-forest trust has been declared in the ARX configuration. You can declare a forest-to-forest trust with the [active-directory forest-trust](#) command. Each trust relationship appears as one row in the table, with the following fields:

Forest-1 and

Forest-2 are the two forests in the trust relationship. Clients from either of these forests can access CIFS services in the other.

Trust Type is always “bidirectional” in the current release. Clients in Forest-1 can access services in Forest-2, and clients in Forest-2 can access services in Forest-1.

**Sample**

`bstnA# show active-directory`

shows all active-directory forests on the ARX. See [Figure 16.2](#) for sample output.

**Related Commands**

[active-directory-forest](#)

## show active-directory status

**Purpose** Use the `show active-directory status` command to see the status of all Domain Controllers (DCs) in the Active-Directory configuration.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show active-directory status [detailed]`  
`show active-directory status forest forest-name [detailed]`  
`show active-directory status domain domain-name [detailed]`

**detailed** (optional) expands the output to include statistics about each DC's health.

**forest-name** (optional, 1-256 characters) identifies a particular forest to show.

**domain-name** (optional, 1-256 characters) identifies a particular domain.

**Guidelines: Output** The top line in the output shows the **Offline timeout**, which is the time that the ARX waits for a response from a DC before declaring it offline. This is a system-wide variable, set with the [kerberos health-check threshold](#) command.

The remaining output is divided into sections, one per control-plane processor. Each processor section has the following heading:

**PROCESSOR *slot.proc***, where *slot.proc* identifies the processor.

Each processor section contains a subsection for each AD forest. The subsections have the following headings:

**Forest** is the name of the AD forest (set by the [active-directory update seed-domain](#) or the [active-directory-forest](#) command).

One table per DC appears in each forest subsection. Each DC table contains the following fields:

**Domain Name** is the Windows domain.

**Domain Controller** is the IP address of one of the domain's DCs.

**Status** is "Active," "Backup," "Offline," "Unusable," or "NoStatus."

- "Active" means that the processor is using this DC for authentication.
- "Backup" indicates that there are redundant DCs configured for this domain, where one or more other DCs are "preferred" over this one (see below), and the processor is currently using the DC's redundant peer(s).
- "Offline" indicates that the DC is unreachable. An unreachable DC is one that fails to respond to an LDAP query before the time set for the [kerberos health-check threshold](#). The maximum time appears in the **Offline timeout** field at the top of the output.

**Guidelines: Output  
(Cont.)**

- “Unusable” means that the DC is not usable for forest-to-forest trusts (configured with the [active-directory forest-trust](#) command) because the ARX cannot verify that it is a Windows 2003 (or later) server. The DC must confirm that it is running Windows 2003 or a later release to be usable for these trusts.

If such a DC is in the forest, no [cifs](#) service can support the recommended “constrained delegation” feature (described with the [domain-join](#) command).

- “NoStatus” appears very briefly before the processor first queries the DC. You are unlikely to ever see this status.

Preferred is “1” (one) if this DC is on the preferred list for its domain, or “0” (zero) otherwise. If any preferred DC is online for a given domain, a processor chooses the DC for Active status instead of its non-preferred peers. The preferred DCs are the DCs in the same AD site as the ARX (see [active-directory update seed-domain](#) or [active-directory update forest](#)), or you can manually set the DC preference with an optional flag in the [forest-root](#), [child-domain](#), or [tree-domain](#) commands.

**Guidelines: Forest  
Trust Table**

The Forest Trust table only appears if at least one forest-to-forest trust has been declared in the ARX configuration. You can declare a forest-to-forest trust with the [active-directory forest-trust](#) command. Each trust relationship appears as one row in the table, with the following fields:

**Forest-1** and

**Forest-2** are the two forests in the trust relationship. Clients from either of these forests can access CIFS services in the other.

**Trust Type** is always “bidirectional” in the current release. Clients in Forest-1 can access services in Forest-2, and clients in Forest-2 can access services in Forest-1.

**Last Transition (UTC)** is the timestamp showing the most-recent status change. (This time stamp is in UTC, not local time.) The ARX periodically checks each [forest-root](#) DC to confirm that it is online. If the forest has redundant root DCs, only the active DC has its status checked. The next field shows the results of the status check.

**Status** should be “Forest roots are online.” This indicates that the trust is functional. If either or both are offline, check the connectivity to each DC, and the DC itself. You can use the [show active-directory](#) command to identify the forest root(s) for each forest.

**Guidelines: Detailed Output**

If you use the detailed flag in the command, the output changes to a separate table for each DC. The DC tables are organized by processor, then by forest. Each table contains the following fields:

**Domain Name** is the DC's Windows domain.

**Domain Controller** is the IP address of one of the domain's DCs.

**Status** is "Active," "Backup," "Offline," "Unusable," or "NoStatus," as described above.

**Active Count** is the number of times that the current DC has been Active for its domain.

**Health Check Failure** counts the number of times that the ARX failed to connect to the DC.

**Health Check Timeout** counts the number of times that the DC exceeded the [kerberos health-check threshold](#) before responding to the LDAP query.

**Transition Total** is the count of transitions to "Active" from some other status.

**Last Transition (UTC)** is the timestamp for the most-recent transition, in Coordinated Universal Time (known as UTC).

**LDAP Health Check** shows round-trip times for the LDAP query and response. These statistics only appear for a DC that is either "Active" or "Backup."

- **Since last transition** displays the average, minimum, and maximum round-trip times since the last time a new DC became reachable in this domain.
- **Last 5/30/60 minutes** shows the average round-trip times over the last 5 minutes, the last half hour, and the last hour.

**Guidelines: Alternative Commands**

Use [show active-directory](#) to see the switch's representation of the AD configuration.

**Samples**

```
bstnA# show active-directory status
```

shows the status of all AD forests configured on the current switch. See [Figure 16.3 on page 16-18](#) for sample output.

```
bstnA# show active-directory status domain FDTESTNET.NET
```

shows the status of one AD domain. See [Figure 16.4 on page 16-19](#) for sample output.

**Related Commands**

## show proxy-user

**Purpose** The ARX needs user credentials (a username and password) for autonomous operations, such as migrating files from one filer to another. These credentials are called a *proxy user*. Use this command to view a list of configured proxy-user configurations on the switch.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show proxy-user [name]`

*name* (optional; 1-32 characters) is the name of a proxy user. If no name is specified, this command shows all configured proxy users.

**Guidelines** This command shows a table of proxy-user configurations, one per row. Each row contains the following columns:

**Name** identifies the proxy-user object. You choose this when you use the [proxy-user](#) command to create the proxy-user configuration.

**Windows Domain** identifies the domain of the proxy user, if there is one. This is typically an FQDN. Use the [windows-domain \(gbl-proxy-user\)](#) command to change this.

**Pre-Win2k** is the domain name that the ARX uses for its NTLM authentications; some filers do not accept FQDNs for NTLM. This is an old-style domain name, in the format used by Windows networks before Windows 2000. By default, this name is discovered automatically, through [active-directory update seed-domain](#). If this domain's name was not discovered, the ARX uses the first name in the Windows Domain's FQDN, up to 15 characters before the first period. You can manually set the name with an option in the [windows-domain \(gbl-proxy-user\)](#) command, though we recommend setting it at the AD and discovering it from there.

**User** is the username used by this proxy-user object. If the ARX uses this proxy-user object, this is the username it presents to back-end filers. You can change this with the [user \(gbl-proxy-user\)](#) command.

**Description** shows a descriptive string for the proxy user, if one is defined. You can use the [description \(gbl-proxy-user\)](#) command to add a description to a proxy-user configuration.

Include a proxy-user "name" to show details for that configuration only.

**Sample** `bstnA> show proxy-user`

shows all proxy-user configurations on the ARX. See [Figure 16.5 on page 16-21](#) for sample output.

**Related Commands** [proxy-user](#)  
[windows-domain \(gbl-proxy-user\)](#)  
[user \(gbl-proxy-user\)](#)  
[show ntlm-auth-db](#)

---

*Figure 16.5 Sample Output: show proxy-user*

```
bstnA> show proxy-user
```

| Name       | Windows Domain<br>Description                                  | Pre-Win2k  | User Name     |
|------------|----------------------------------------------------------------|------------|---------------|
| acoProxy1  | WWMEDNET.COM<br>jq's admin account                             |            | jqprivate     |
| acoProxy3  | FDTESTNET.COM                                                  | BOSTONCIFS | jqtester      |
| cifs_admin | MEDARCH.ORG                                                    |            | Administrator |
| nas_admin  |                                                                |            | root          |
| ny_admin   | WELLS.ME.ORG                                                   |            | jqpublic      |
| acoProxy2  | MEDARCH.ORG<br>user with backup and admin creds on our servers |            | jqpublic      |

## user (gbl-proxy-user)

**Purpose** The ARX needs user credentials (a username and password) for autonomous operations, such as migrating files from one filer to another. These credentials are called a *proxy user*. Use this command to enter a username and password for the current proxy-user configuration.  
Use the `no user` command to remove the username from the current configuration.

**Mode** gbl-proxy-user

**Security Role(s)** crypto-officer

**Syntax** `user username`  
`no user`

*username* (1-64 characters) is a valid username you choose for this proxy-user configuration. This is typically a Windows user, though it may be a Unix user for certain applications of the proxy user (for example, see the documentation for [proxy-user \(gbl-filer\)](#)). Any Windows proxy user must be a member of the Backup Operators or Administrators group on all filers that use these credentials; see below for details.

◆ **Note**

---

*The password must be the same password set for this user in the external network. If you change the user's password on the network, you must also change it on the switch through this command.*

**Default(s)** None

**Guidelines** The system prompts you for a password, then prompts you to validate the password by entering it a second time. Enter a password (it is masked with asterisk (\*) characters as you enter it) and confirm when prompted.

**Guidelines: CIFS Proxy User**

A CIFS-supporting namespace can contain one or more managed volumes, and uses a proxy user as its identity for accessing CIFS shares behind those volumes. The proxy user requires specific privileges to access those CIFS shares. You must set these privileges on every CIFS filer or server behind every managed volume in the proxy user's namespace.

Minimally, the proxy user must have Backup Operator privileges at all of its filers. This means that the user you enter with this command must be a member of the Backup Operators group at every filer/server behind every managed volume. Backup Operator privileges are required for importing shares into the volume (with the [enable \(gbl-ns-vol-shr\)](#) command) and for migrating files onto the share. Also, verify that the user account has “full control” (read and change control) at the back-end shares to be used in managed volumes.

If a managed volume supports

- Access-Based Enumeration (ABE; see [cifs access-based-enum](#))
- CIFS subshares (see the documentation for the [filer-subshares](#) command), or
- file-history archiving (a [snapshot rule](#) with a file-history [archive](#)),

the proxy user should belong to the Administrators group on that volume's filers/servers. The volume software needs this higher level of access for file-path queries, which are required for all of the above features.

If the user is a member of the local Backup Operators or Administrators group on a Windows cluster, add the Windows user to the group at every cluster node. The local groups are not shared in the cluster.

A Windows server with User Access Control (UAC) places further constraints on a CIFS proxy user. This requires a user account in the Domain Users group. UAC was introduced with Windows Server 2008.

**Guidelines: Changing the Password**

For security reasons, you may choose to change the password for the proxy-user account from time to time. For a Windows proxy user, this change must occur in two places: the Active Directory, where the corresponding Windows user is defined, and in the ARX configuration. Use the following steps to make the change:

- Change the password on a Domain Controller (DC).
- Wait for all of the DCs in the proxy user's Windows Domain to synchronize their databases.
- After the DCs are synchronized with the new password, re-run this command to change the password on the ARX.

During the time that the proxy-user password on the ARX does not match the one in the external Active Directory, the volumes that use the proxy user cannot access any of their back-end-CIFS storage. This prevents the managed volumes from performing autonomous operations, such as policy-driven migrations, and causes the CIFS shares to go “offline.” We recommend that you perform this procedure during non-busy hours.

```

Sample bstnA(gbl)# proxy-user acoProxy2
bstnA(gbl-proxy-user[acoProxy2])# user jqpublic
Password: *****
Validate Password: *****
bstnA(gbl-proxy-user[acoProxy2])#

```

**Related Commands** [proxy-user](#)  
[show proxy-user](#)

## windows-domain (gbl-proxy-user)

**Purpose** A *proxy user* is a set of user credentials (a username and password) that the ARX can use to access its back-end filers. The ARX uses the proxy-user credentials when it must perform autonomous operations, such as importing files into a managed volume. For a Windows proxy user, you can use this command to identify the Windows domain.  
Use the **no** form of the command to remove the domain name.

**Mode** gbl-proxy-user

**Security Role(s)** crypto-officer

**Syntax** `windows-domain domain-name [pre-win2k-name old-style-domain]`  
`no windows-domain`

*domain-name* (1-64 characters) is the name of the Windows domain to identify with this Windows user. This must be a Fully-Qualified-Domain Name (FQDN) for the proxy user to authenticate through Kerberos. Choose a domain in the same Active-Directory forest as the filers.

*old-style-domain* (optional, 1-15 characters, no periods) is the legacy Windows domain for the proxy-user account. The proxy user may have to use NTLM when it authenticates with back-end filers, and not all back-end filers accept an FQDN for NTLM authentication. Use this option only if the default (below) is incorrect; this option is rarely necessary.

**Default(s)** *old-style-domain* - The old-style name discovered with [active-directory update seed-domain](#). If the old-style name was never discovered for this domain, the ARX uses the first part (before the first ".", up to 15 characters) of the FQDN in the *domain-name*.

**Guidelines** When assigned to a namespace through [proxy-user \(gbl-ns\)](#), a proxy-user provides a login ID for the ARX to access back-end filers. The ARX uses this account for imports, file migrations from one back-end filer to another, and other autonomous operations.  
Ideally, the domain should be one that the ARX has already discovered with [active-directory update seed-domain](#). If you are creating the proxy user before you run that command, the CLI warns that the domain is unknown. This warning is designed for situations where the domain is typed incorrectly, and is benign in this case.  
Use the [show proxy-user](#) command to view all configured proxy users, and their associated Windows domains and usernames.

---

**Samples** bstnA(gbl)# **proxy-user acoProxy2**  
bstnA(gbl-proxy-user[acoProxy2])# **windows-domain medarch.org**

% INFO: The windows-domain name 'medarch.org' is not in active-directory-forest configuration. The specified name is accepted, but reconfigure the windows-domain if it is misconfigured.

bstnA(gbl-proxy-user[acoProxy2])#  
sets the proxy-user's domain to medarch.org. The informational message is benign if it occurs before anyone has run the [active-directory update seed-domain](#) command.

stoweA(gbl)# **proxy-user acoProxy3**  
stoweA(gbl-proxy-user[acoProxy3])# **windows-domain FDTESTNET.COM**  
**pre-win2k-name BOSTONCIFS**  
stoweA(gbl-proxy-user[acoProxy3])#

sets another proxy-user's domain to FDTESTNET.COM, but specifies a legacy-domain name of "BOSTONCIFS." The last option is only necessary if this pre-Win2K name was not discovered earlier with the [active-directory update seed-domain](#) command.

**Related Commands** [ntlm-auth-server](#)  
[proxy-user \(gbl-ns\)](#)  
[show global-config namespace](#)  
[show proxy-user](#)

---

---

## Management Access

---

---

---

# authentication

**Purpose** Use the `authentication` command to set a primary, secondary, or tertiary authentication service for the current management-access point.

Use the `no` form of the command to remove an authentication service.

**Mode** `cfg-mgmt-access`

**Security Role(s)** `crypto-officer`

**Syntax** `authentication {primary | secondary | tertiary}  
{active-directory | radius | local}  
no authentication {primary | secondary | tertiary}`

**primary | secondary | tertiary** is a required choice for setting the precedence of this authentication service:

**primary** is the preferred authentication service,

**secondary** is the authentication service to be used if the primary service fails, and

**tertiary** is used if the secondary fails, too.

**active-directory | radius | local** is another required choice, for setting the authentication type.

**active-directory** authenticates through the externally-configured Active Directory. (You can use the [active-directory update seed-domain](#) command to automatically discover the Active Directory (AD) and all of its Domain Controllers.) This option allows Windows clients with sufficient privileges (see below) to log in with their Windows credentials.

**radius** authenticates using a RADIUS (Remote Authentication Dial-In User Service) server on the network.

**local** authenticates using services local to the ARX.

**Default(s)** None

**Guidelines** The management-authentication software uses its primary authentication method first and tries the secondary method only if the primary method fails. The software then drops down to the tertiary method if the secondary method fails.

Use the [show management access](#) command to show the current configuration mapping of authentication services to management-access points.

To remove an authentication service with `no authentication`, you must remove the lowest-precedence service first. For example, if you have a management service configured with primary, secondary, and tertiary authentication, you must remove the tertiary authentication service before you can remove the secondary service.

**Guidelines:  
Active-Directory  
Authentication**

The **active-directory** option requires additional configuration: you must also identify Windows-user groups with sufficient privileges for administrative access. Use the **group** command to create a group with the same name as the desired Windows group, then use **windows-domain (gbl-group)** to declare a domain for that group, and finally use the **role** command to add one or more administrative roles for that group. For example, you could create a “Domain Admins” group in the “medarch.org” domain and give it highly-privileged roles, such as “storage-engineer” and “crypto-officer.” As another example, you could create a “Domain Users” group with the lesser role of “operator.”

The ARX only considers a user's first 1000 Active Directory groups when using AD authentication. If the AD group needed for authentication is not within the first 1000 groups returned by the DC, the user will not be able to authenticate.

To ensure that you can log in during a large-scale AD failure, we recommend that you configure a secondary or tertiary local service behind any primary AD service.

**Guidelines: RADIUS  
Authentication**

Before you configure RADIUS authentication, use the **show radius-server** command to verify that a RADIUS server is properly configured. To insure against RADIUS-server failures, we recommend that you configure a secondary local service behind any primary RADIUS service.

**Guidelines: Keep  
Each User Account in  
Only One  
Authentication  
Service**

If the same username is defined for two or more authentication types (such as RADIUS and AD) with different passwords, the user can log in with either password. The ARX software uses the given username/password combination for all authentication methods until authentication succeeds, or until all authentication methods are exhausted. For example, if the “jsmith” user has one password defined at the RADIUS server and a different password defined in the Active Directory, and both those authentication services are assigned to the HTTPS access point, jsmith can log into the GUI with either password.

This situation can create security issues, so we recommend defining the user account in only one authentication database (RADIUS, AD, or locally on the ARX).

**Guidelines:  
Authentication for the  
ARX API**

A client application can access the *ARX API* to make queries about the ARX configuration and state. These queries come through one of two **management access** points, **http-api** or **https-api**. Each query from the client application results in a separate authentication.

We recommend using **local** authentication only for the API access points; **active-directory** or **radius** authentication may create an excessive load on your domain controllers (for **active-directory**) or RADIUS server. If you must duplicate accounts in more than one database, we recommend using the same password for all of them.

**Samples**

```
bstnA(cfg)# management access https
bstnA(cfg-mgmt-access[HTTPS])# authentication primary active-directory
sets authentication configuration for HTTPS (GUI) access: the primary
authentication service is Active Directory. This allows an administrator to log into
the GUI with his or her Windows username and password, provided the username
is a member of a properly-configured Windows group (see the Guidelines above).
```

```
bstnA(cfg-mgmt-access[Telnet])# no authentication secondary
removes the secondary authentication service from Telnet.
```

**Related Commands** [management access](#)  
[show management access](#)  
[radius-server](#)  
[show radius-server](#)

## auth-port (gbl-radius)

**Purpose** Most RADIUS servers listen at a well-known port. By default, the ARX sends all RADIUS traffic to that port. Use the `auth-port` command to change the destination-port number for outbound RADIUS traffic.

Use the `no` form of the command to reset the port number to the default.

**Mode** gbl-radius

**Security Role(s)** crypto-officer

**Syntax** `auth-port port-number`  
`no auth-port`

*port-number* (1024-65535) is the destination-port number at the RADIUS server.

**Default** 1812

**Sample** `bstnA(gbl)# radius-server 192.168.25.207`  
`bstnA(gbl-radius[192.168.25.207])# auth-port 5555`  
`bstnA(gbl-radius[192.168.25.207])# ...`

changes the port number to 5555 for the RADIUS server at 192.168.25.207:

**Related Commands** [radius-server](#)  
[key \(gbl-radius\)](#)  
[retries \(gbl-radius\)](#)  
[timeout \(gbl-radius\)](#)

---

## clear session

**Purpose** Use the `clear session` command to end a current CLI or GUI user session on the ARX.

**Mode** priv-exec

**Security Role(s)** crypto-officer, network-engineer, or network-technician

**Syntax** `clear session login-id`

*login-id* (1-128 characters) is the ID of the session to disconnect. The [show sessions](#) command shows a list of valid IDs.

**Guidelines** If you choose the login ID for the current CLI session, a prompt warns you that you will be disconnected if you proceed. Enter **yes** to clear the CLI session and disconnect. Use the [show sessions](#) command to view the list of current user sessions.

**Samples** `bstnA# clear session 25250`  
ends session 25250, a CLI session.

`bstnA# clear session F8DAB350CE624E50AD767A717E931826`  
ends a GUI session.

**Related Commands** [show sessions](#)

## clear statistics authentication

|                         |                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use this command to clear all login statistics, shown in the <code>show statistics authentication</code> output.                                                      |
| <b>Mode</b>             | priv-exec                                                                                                                                                             |
| <b>Security Role(s)</b> | crypto-officer, network-engineer, or network-technician                                                                                                               |
| <b>Syntax</b>           | <code>clear statistics authentication</code>                                                                                                                          |
| <b>Default(s)</b>       | None                                                                                                                                                                  |
| <b>Guidelines</b>       | Use the <a href="#">show statistics authentication</a> command to view the number of successful and failed login attempts. This command clears all of those counters. |
| <b>Sample</b>           | <code>bstnA# clear statistics authentication</code>                                                                                                                   |
| <b>Related Commands</b> | <a href="#">show statistics authentication</a>                                                                                                                        |

---

## key (gbl-radius)

**Purpose** Use the `key` command to set the key (password or shared secret) on the ARX to match the key on the RADIUS server. The switch and its RADIUS server must have identical keys.

Use the `no` form of the command to erase the key. Erasing the key disables authentication at the current RADIUS server.

**Mode** gbl-radius

**Security Role(s)** crypto-officer

**Syntax** `key`  
`no key`

**Default(s)** None

**Guidelines** The CLI challenges you for the key, and you must re-enter it at the Validate Key prompt. See the example below.

**Sample**

```
bstnA(gbl)# radius-server 192.168.25.201
bstnA(gbl-radius[192.168.25.201])# key
Key: $3cretPa$$w0rd
Validate Key: $3cretPa$$w0rd
bstnA(gbl-radius[192.168.25.201])# ...
```

The following example uses the “\$3cretPa\$\$w0rd” key:

**Related Commands** [radius-server](#)

## management access

**Purpose** You can manage the ARX through the following management-access points:

- Console (a serial connection),
- Telnet (on a management interface),
- SSH (on a management interface),
- HTTP (on a management interface),
- HTTPS (on a management interface),
- HTTP for the API (on a management interface),
- HTTPS for the API (on a management interface), and
- SNMP.

Each of these services is gated by an *authentication service*. Use the **management access** command to start configuring authentication service(s) for a management-access point.

Use the **no** form of the command to remove all authentication services from a management-access point, thus shutting down access.

**Mode** `cfg`

**Security Role(s)** `crypto-officer`

**Syntax** `management access {console | telnet | ssh | http | https |  
http-api | https-api | snmp | all}`

`no management access {console | telnet | ssh | http | https |  
http-api | https-api | snmp | all}`

**Default(s)** `console` - access permitted, authentication through a local service (as opposed to a remote Active-Directory service or RADIUS server)

`telnet` - access denied

`ssh` - access permitted through any management interface, local authentication

`http` - access denied

`https` - access permitted through any management interface, local authentication

`http-api` - access denied

`https-api` - access denied

`snmp` - access denied

**Guidelines** Administrators can access the CLI through telnet or SSH, they can access the GUI through HTTP or HTTPS, and they can access the API through HTTP or HTTPS. SSH and HTTPS, the secure protocols, are available by default for the CLI and the GUI.

You can use this command to start provisioning the management-IP interfaces that accept these communication protocols, and the authentication services (Active Directory, RADIUS, or local) to be used. This command puts you into `cfg-mgmt-access` mode, where you use the [permit](#) command to permit access through one or more management IPs. You can also use the [authentication](#) command to configure a primary, secondary, and/or tertiary authentication service.

If you disable all management access to the GUI or the API, you shut down those services. Conversely, you can restart those services by permitting management access through any interface.

Use the [show management access](#) command to show the current configuration mapping of access points to their authentication services and available interfaces.

**Guidelines: API** You can use a SOAP client to access the API. The HTTP-API port is 83, and the HTTPS-API port is 843. Use the following URL syntax to access the API documentation through HTTP:

**`http://arx-management-ip:83/arx-api/`**

where *arx-management-ip* is either the out-of-band management-IP address ([interface mgmt](#)) or an in-band (VLAN) management-ip address ([interface vlan](#)). The [permit](#) command determines which of these address types are available for access. Use [show interface mgmt](#) and/or [show interface vlan](#) to find the IP addresses for each interface.

This URL accesses the same documentation through HTTPS:

**`https://arx-management-ip:843/arx-api/`**

where *arx-management-ip* is a valid management IP, as described above.

You can use the [show statistics api](#) command to find usage statistics for the API.

The API supports notifications of file and directory changes in any managed volume. To support these API queries, you create a [notification rule](#) in any desired managed volume.

**Samples**

```
bstnA(cfg)# management access console
bstnA(cfg-mgmt-access[Console])# ...
 starts configuring authentication for console access. The console port is a serial
 port, labeled Console on the front panel.
```

```
bstnA(cfg)# management access all
bstnA(cfg-mgmt-access) ...
 starts configuring authentication for all management-access points at once.
```

```
bstnA(cfg)# no management access telnet
bstnA(cfg)# ...
 prevents any management access through Telnet.
```

**Related Commands**

- [permit](#)
- [authentication](#)
- [show management access](#)

## permit

**Purpose** Use the `permit` command to allow access to the current management-access point. You can permit access through the out-of-band MGMT interface, any in-band (VLAN) interface, or all management interfaces. Use `no permit` to deny access.

**Mode** `cfg-mgmt-access`

**Security Role(s)** `crypto-officer`

**Syntax** `permit {vlan | mgmt | all}`  
`no permit {vlan | mgmt | all}`

`vlan | mgmt | all` is a required choice:

**vlan** permits (or denies) access through any in-band (VLAN) management interface. Use the [show interface vlan](#) command to see all in-band management interfaces.

**mgmt** permits or denies access through the out-of-band management interface, labeled MGMT on the front panel. Use the [show interface mgmt](#) command to see the configuration for this interface. This option is unavailable on the ARX-VE, which has no out-of-band management interface. This option also may not apply to the ARX-1500 or ARX-2500, where the out-of-band management interface may be re-purposed as a standard client/server port (see the documentation for [interface mgmt](#)).

**all** permits or denies access through all of the above.

**Default(s)** For each management-access point:

Telnet - no permit

Ssh - permit

Snmp - no permit

**Guidelines** This does not apply to the Console, which always permits serial access.

Use [show management access](#) to see which management-access points are currently available.

**Samples**

```
bstnA(cfg)# management access telnet
bstnA(cfg-mgmt-access[Telnet])# permit all
bstnA(cfg-mgmt-access[Telnet])# ...
 permits Telnet access through MGMT and VLAN-management interfaces.
```

```
bstnA(cfg)# management access ssh
bstnA(cfg-mgmt-access[SSH])# no permit mgmt
bstnA(cfg-mgmt-access[SSH])# ...
 denies SSH access through the out-of-band MGMT interface:
```

**Related Commands** [management access](#)  
[show interface vlan](#)  
[show interface mgmt](#)  
[show management access](#)

---

# radius-server

**Purpose** Use the `radius-server` command to configure/identify a RADIUS server as an authentication provider for the ARX. You can use this command multiple times to configure multiple RADIUS servers.

Use the `no` form of the command to remove one RADIUS-server configuration.

**Mode** gbl

**Security Role(s)** crypto-officer

**Syntax** `radius-server hostname-or-ip-address`  
`no radius-server`

*hostname-or-ip-address* (1-128 characters or an IP address) is the hostname or IP address of a RADIUS server.

**Default(s)** None

**Guidelines** This command places you in gbl-radius mode. From gbl-radius mode, use the [key \(gbl-radius\)](#) command to enter the shared-secret from the RADIUS server. You can change the timeout and/or retry interval with the [timeout \(gbl-radius\)](#) and [retries \(gbl-radius\)](#) commands. If the RADIUS server listens at a port other than the well-known port, you can use the [auth-port \(gbl-radius\)](#) command to adjust the port configuration.

To use a RADIUS server, you must configure the server itself as well as the ARX. For details about configuring the external RADIUS server, see [Chapter 8, Configuring Management Access](#), in the [ARX® CLI Network-Management Guide](#).

### ◆ Important

---

*Before you remove a RADIUS server through the `no` command, ensure a backup authentication method is in place for management services.*

**Sample** `bstnA(gbl)# radius-server 192.168.25.201`  
`bstnA(gbl-radius[192.168.25.201])# ...`  
starts configuring a RADIUS server at 192.168.25.201:

**Related Commands** [auth-port \(gbl-radius\)](#)  
[key \(gbl-radius\)](#)  
[retries \(gbl-radius\)](#)  
[timeout \(gbl-radius\)](#)  
[show radius-server](#)  
[show management access](#)

## retries (gbl-radius)

|                         |                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>retries</code> command to change the connection-retry interval for communication with RADIUS servers.<br>Use the <code>no</code> form of the command to reset the retry interval to the default.                                        |
| <b>Mode</b>             | gbl-radius                                                                                                                                                                                                                                            |
| <b>Security Role(s)</b> | crypto-officer                                                                                                                                                                                                                                        |
| <b>Syntax</b>           | <code>retries <i>number</i></code><br><code>no retries</code><br><br><i>number</i> (3-65535) is the number of times the switch attempts to connect to the RADIUS server before declaring a failure.                                                   |
| <b>Default(s)</b>       | 3                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>       | By default, the switch retries a failed connection three times before it quits. If all retries fail, the request fails. A failed request causes a fallback to the next level of authentication service (secondary or tertiary), if one is configured. |
| <b>Sample</b>           | <pre>bstnA(gbl)# radius-server 192.168.25.207 bstnA(gbl-radius[192.168.25.207])# retries 4 bstnA(gbl-radius[192.168.25.207])# ...</pre> sets the number of retries for the RADIUS server at 192.168.25.207:                                           |
| <b>Related Commands</b> | <a href="#">radius-server</a><br><a href="#">timeout (gbl-radius)</a>                                                                                                                                                                                 |

## show management access

- Purpose** Use the `show management access` command to show the authentication services configured for system management.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show management access`
- Guidelines** Service is Console, Telnet, SSH, HTTP, HTTPS, SNMP, HTTP-API, or HTTPS-API. This is the management-access point, a point of entry for a system administrator. Use the [management access](#) command to edit one or all of these management-access configurations.
- Primary is the primary authentication service for this management-access point. The choices are “AD” (for Active-Directory authentication, which allows Windows users to authenticate with their Windows credentials), “local” (for authentication service that runs on the ARX), or “RADIUS” (for authentication at a remote RADIUS server).
- Secondary and Tertiary are backup authentication services. If the primary service fails, the switch uses the secondary service; if the secondary authentication fails too, the switch falls back to the tertiary service. Use the [authentication](#) command to reset the primary, secondary, or tertiary service.
- Allowed Interface is “VLAN,” “Management,” or both. “VLAN” indicates that administrators can gain access through any in-band (VLAN) management interface. “Management” indicates that access is allowed through the out-of-band management interface, labeled MGMT on the front panel. Use the [permit](#) command to permit VLAN and/or MGMT access.
- Sample** See [Figure 17.1](#), below.
- Related Commands** [management access](#)  
[authentication](#)  
[permit](#)

*Figure 17.1 Sample Output: show management access*

```
bstnA> show management access
```

| Service   | Primary | Secondary | Tertiary | Allowed Interface |
|-----------|---------|-----------|----------|-------------------|
| Console   | Local   | None      | None     | N/A               |
| Telnet    | AD      | RADIUS    | Local    | VLAN/Management   |
| SSH       | AD      | Local     | None     | VLAN/Management   |
| HTTP      | None    | None      | None     | None              |
| HTTPS     | AD      | Local     | None     | VLAN/Management   |
| SNMP      | N/A     | N/A       | N/A      | VLAN/Management   |
| HTTP-API  | None    | None      | None     | None              |
| HTTPS-API | None    | None      | None     | None              |

## show radius-server

- Purpose** Use the `show radius-server` command to display a summary of all RADIUS servers known to the switch.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show radius-server`
- Guidelines** The `show` command displays multiple RADIUS servers in the order they were configured. The switch uses them in this order; if the first server fails, the switch uses the second one, and so on.
- Hostname is the name or IP address of the RADIUS server.
- Authport is the destination port at the RADIUS server.
- Acctport is the port used for accounting; currently not used.
- Timeout is the current connection-timeout interval.
- Retries is the current connection-retry interval.
- Sample** `bstnA(gbl)# show radius-server`  
shows a summary of all RADIUS servers known to the switch.  
See [Figure 17.2 on page 17-16](#) for sample output.
- Related Commands** [radius-server](#)  
[auth-port \(gbl-radius\)](#)  
[retries \(gbl-radius\)](#)  
[timeout \(gbl-radius\)](#)  
[show management access](#)

*Figure 17.2 Sample Output: show radius-server*

```
bstnA# show radius-server
```

| Hostname       | Authport | Acctport | Timeout | Retries |
|----------------|----------|----------|---------|---------|
| 192.168.25.201 | 1812     | 1813     | 3       | 3       |
| 192.168.25.207 | 5555     | 1813     | 10      | 4       |

## show sessions

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>show sessions</code> command to view all current management sessions on the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Mode</b>             | (any)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Security Role(s)</b> | crypto-officer, network-engineer, or network-technician                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Syntax</b>           | <code>show sessions</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Guidelines</b>       | <p>Each login session is one table in the output, with the following fields:</p> <p><b>Session ID</b> identifies each session. CLI sessions have integer IDs, and GUI sessions have string IDs. The flag, <code>(local session)</code>, appears for the current CLI session.</p> <p><b>Username</b> identifies the administrative user.</p> <p><b>Access</b> is the type of connection. This is the same as the management-access point that you choose with the <code>management access</code> command (for example, console, ssh, or https).</p> <p><b>Connect Time</b> shows how long the session has been running displayed in minutes and hours. If the session has been running less than a minute, a dash is displayed instead of the time.</p> <p><b>Source IP</b> is the IP address from which the user logged in.</p> <p>You can use the <code>clear session</code> with one of the IDs to clear that administrative session, thereby logging off the administrator.</p> |
| <b>Sample</b>           | <pre>bstnA# show sessions</pre> <p>shows the current users logged in to the switch. See <a href="#">Figure 17.3</a>, below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Related Commands</b> | <a href="#">management access</a><br><a href="#">clear session</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Source IP: 192.168.101.57

Session ID: 8395 (local session)
Username: admin
Access: ssh
Connect Time: 0 days, 00:00:52
Source IP: 172.16.100.183

Session ID: 9632
Username: admin
Access: ssh
```

## Chapter 17 Management Access

---

Connect Time: 0 days, 00:00:04  
Source IP: 172.16.100.183

bstnA# ...

# show ssh-host-key

**Purpose** Immediately after you use `ssh-host-key generate` to change the SSH host keys on the switch, you should distribute the new keys to remote SSH clients. Use the `show ssh-host-key` command to show the public host keys.

**Mode** (any)

**Security Role(s)** crypto-officer

**Syntax** `show ssh-host-key [dsa | rsa | rsa1]`

`dsa | rsa | rsa1` selects a particular SSH key; by default, all of them are shown.

`dsa` is the key for DSA over SSHv2,

`rsa` selects the key for RSA over SSHv2, and

`rsa1` chooses RSA over SSHv1. By default, SSHv1 is not supported, use `ssh-v1 enable` to enable SSHv1 support.

**Guidelines** Use the `ssh-host-key generate` command to change all private/public host-key pairs on the switch. Then use this command to see the new public keys and begin distributing them to SSH clients. Install the appropriate public key (DSA, RSA, or RSA1) at each client; refer to the client's SSH documentation for instructions.

**Sample** `bstnA(cfg)# show ssh-host-key`

```
ssh-dss

shows all three public host keys.

**Related Commands** [ssh-host-key generate](#)  
[ssh-v1 enable](#)

---

## show statistics authentication

**Purpose** Use this command to show the statistics on successful and failed management authentications.

**Mode** (any)

**Security Role(s)** crypto-officer, network-engineer, or network-technician

**Syntax** `show statistics authentication`

**Default(s)** None

**Guidelines** Use this command to display the authentication-login statistics. Use the [clear statistics authentication](#) command to clear the current authentication statistics and reset the counters.

For configuration information, use the [show management access](#) command.

**Sample** `bstnA# show statistics authentication`

|                  | Success | Failure |
|------------------|---------|---------|
|                  | -----   | -----   |
| Telnet           |         |         |

| Totals           | 73      | 0       |

displays the login authentication statistics.

**Related Commands** [clear statistics authentication](#)  
[show management access](#)

## ssh-host-key

**Purpose** Some installations manage their SSH host keys with an external application, such as PuTTYgen (on Windows) or ssh-keygen (on Unix). You can use the `ssh-host-key` command to install a host key from one of these applications onto the ARX.

**Mode** config

**Security Role(s)** crypto-officer

**Syntax** `ssh-host-key {rsa | dsa}`

`dsa` | `rsa` selects the type of SSH key to set.

`dsa` is the key for DSA, and

`rsa` selects the key for RSA over SSHv2.

**Default(s)** None

**Guidelines** The CLI prompts for the host key after you enter the command. Copy the private host key from your external application and paste it at this prompt.

The host key must have the following format:

```
-----BEGIN RSA PRIVATE KEY-----
key-text
-----END RSA PRIVATE KEY-----
```

where *key-text* has a <Return> character at the end of each line.

This is the format of a typical text file for a private key. PuTTYgen creates a text file with this format if you load a generated key and select **Conversions -> Export OpenSSH key**. This is also the format you find in `/etc/ssh/ssh_host_*sa_key` on a Linux box with SSH.

As an alternative to installing a pre-generated host key, you can use [ssh-host-key generate](#) to generate random host keys for the ARX.

**Guidelines: Installing the Public Key on SSH Clients**

The ARX generates a new public key to associate with this new private key. The new public key is accessible through [show ssh-host-key](#). You copy the appropriate public key to trusted clients, as described below. The private key remains hidden on the switch.

After the new host key is installed, client machines warn their users that the switch's host key has changed. They must update to the new host key before they authenticate with the ARX. Right after generating new host keys, use the [show ssh-host-key](#) command to show the new public key, then copy and paste it onto the client machine. Refer to the client machine's SSH documentation for the specific configuration file.

SSH clients have the option to skip the host-key check, but we recommend checking the host-key at all times.

**Sample**

---

```
bstnA(cfg)# ssh-host-key rsa
Host Key: -----BEGIN RSA PRIVATE KEY-----
Host Key: MIICWgIBAAKBgQC2SZyBkHgOwnB9Stp+MUMOC0cshEyCsLAovBWFUDgGisjRroB0
Host Key: 5XYm+tmMBVmHzQayILi5XwCUl31dD100MKj09G9GFtSs376wVG8HJmfg2dpQmZwc
Host Key: /TVBxga61c75y38aeXYWDgp0j4NU9V/jM6nz1Sy37g4EThrZjJo1M9digwIBJQKB
Host Key: gB2PZXzLub00SZfG8v+09h3z/bQxISnzI3w6LQDck3auuMgOdavt2874PvQciw8a
Host Key: VBzitR4PZ+C+nrUlFH4VuohP7vYItNY/JC951TpLaY3sqrq8n1GmaYtVtzvtihPm
Host Key: 5Dq+a1hZIn9NPe3WsGghqFDzpubPzyx6uqpBwdYr+ppdAkeA7pYN47KnHIAxNDHT
Host Key: 9jvFXPWQj8HFduPIALQzz23MvNiB4r9Qpvg1Q83zJf7KK6plik2JKed72/PED9wa

| <b>Purpose</b>          | An attacker could use one of the ARX's SSH host keys to pose as the ARX for a "man-in-the-middle attack." To prevent this, you can periodically regenerate the host keys at the switch and distribute them to your SSH-client machines. Use the <code>ssh-host-key generate</code> command to generate new host keys.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Security Role(s)</b> | crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>           | <code>ssh-host-key generate</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Guidelines</b>       | <p>The CLI warns you that this forces all clients to update their host key for the ARX. Enter <b>yes</b> to proceed.</p> <p>This generates three pairs of host keys, one for each encryption protocol (RSA for SSHv1, RSA for SSHv2, or DSA). Each pair has one private key (stored securely in the switch) and one public key (accessible through <a href="#">show ssh-host-key</a>). You copy the appropriate public key to trusted clients, as described below. The private key remains hidden on the switch.</p> <p>After the new host keys are generated, client machines warn their users that the switch's host key has changed. They must update to the new host key before they authenticate with the ARX. Right after generating new host keys, use the <a href="#">show ssh-host-key</a> command to show the new public keys, then copy and paste the appropriate key onto the client machine. Refer to the client machine's SSH documentation for the specific configuration file.</p> <p>SSH clients have the option to skip the host-key check, but we recommend checking the host-key at all times.</p> <p>To install a pre-created host key on the ARX, use the <a href="#">ssh-host-key</a> command in <code>cfg</code> mode.</p> |
| <b>Sample</b>           | <pre>bstnA# ssh-host-key generate Warning: this command replaces the current SSH host keys with new key material. Host public keys must be redistributed to SSH clients following this action. Proceed? [yes/no] yes bstnA#       generates new SSH host keys for the "bstnA" switch.</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Related Commands</b> | <a href="#">show ssh-host-key</a><br><a href="#">ssh-host-key</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

---

## ssh-v1 enable

**Purpose** SSHv1 (as opposed to SSHv2) has well-documented security holes and is therefore not supported by default. Some installations only support SSHv1, so you can use the `ssh-v1 enable` command to enable it on the current switch.

Use the `no` form of the command to disable SSHv1 and return to v2-only support.

**Mode** `cfg`

**Security Role(s)** `crypto-officer`

**Syntax** `ssh-v1 enable`  
`no ssh-v1 enable`

**Default(s)** `no ssh-v1 enable`

**Guidelines** We do not recommend supporting SSHv1 for management access. This command exists for sites where there are SSH clients that do not support SSHv2. SSHv2 is enabled in any case.

**Samples** `bstnA(cfg)# ssh-v1 enable`  
enables SSHv1 (in addition to SSHv2).

`bstnA(cfg)# no ssh-v1 enable`  
disables SSHv1.

### Related Commands

## timeout (gbl-radius)

**Purpose** Use the `timeout` command to change the timeout interval for communication with RADIUS servers.

Use the `no` form of the command to reset the timeout interval to the default.

**Mode** gbl-radius

**Security Role(s)** crypto-officer

**Syntax** `timeout milliseconds`  
`no timeout`

*milliseconds* (3-65535) is the number of milliseconds to wait for a server response before timing out.

**Default(s)** 3

**Guidelines** After the timeout expires, the switch retries its request as many times as specified through the [retries \(gbl-radius\)](#) command. If all retries fail, the request fails, which causes fallback to the next level of authentication service (secondary or tertiary), if one is configured.

**Samples** `bstnA(gbl)# radius-server 192.168.25.207`  
`bstnA(gbl-radius[192.168.25.207])# timeout 10`  
`bstnA(gbl-radius[192.168.25.207])# ...`  
changes the timeout to 10 milliseconds for the RADIUS server at 192.168.25.207:

## CIFS Authentication

---

---

---

# active-directory-forest

**Purpose** A CIFS front-end service must understand the Active-Directory (AD) hierarchy in its network. That is, the CIFS service must know where to find the correct DC for each domain in the AD forest. The ARX database requires a representation of the AD forest, with the IP addresses of the DCs that control each domain.

Use the `active-directory-forest` command to start manually configuring one AD-forest representation on the ARX.

Use `no active-directory-forest` to remove one AD-forest configuration from the switch.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `active-directory-forest forest-name`  
`no active-directory-forest forest-name`

*forest-name* (1-256 characters) is the name you choose for the forest.

**Default(s)** None

**Guidelines** As an alternative to this command, you can automatically discover an AD forest in your network by using the `active-directory update seed-domain` command. After the forest is configured on the ARX, you can periodically use `active-directory update forest` to re-synchronize the ARX configuration with the actual AD-forest configuration.

The `active-directory-forest` command starts the process of manually describing an AD forest to the ARX. This command places you in `gbl-forest` mode, where you identify all of the domains in the AD forest, along with the DCs that manage them. Use the `forest-root` command to identify each DC for the forest root.

Domains in an AD forest have parent-child relationships based on their names. For example, the forest-root domain, “myco.com,” can have child domains named “usa.myco.com” and “britain.myco.com.” The “usa.myco.com” domain can have its own child domain named “ne.usa.myco.com.” From `gbl-forest` mode, use the `child-domain` command to identify a child domain.

A forest can also support trees that are outside the root’s domain. These are domains with two-way-transitive-trust relationships with one or more domains in the root tree. To continue the above example, a tree domain named “nonprofit.org” may also be trusted by “myco.com,” and it may have a child domain named “euro.nonprofit.org.” From `gbl-forest` mode, use the `tree-domain` command to identify an external tree domain. You use the `child-domain` command to assign a child to the tree domain; the name links each child to the correct parent.

**Guidelines: Dynamic DNS** Kerberos authentication requires an up-to-date DNS database to map front-end CIFS services to their IP addresses. To facilitate DNS updates as CIFS services are added and removed, you can use the `name-server` command to identify a dynamic-DNS server for each domain in the forest. In many cases, the DC itself can also double as the name server for its domain.

**Guidelines:** For AD forests with two-way-trust relationships, where clients from one forest are allowed to access CIFS services from the other forest, you can use the **active-directory forest-trust** command to declare that trust relationship in the ARX configuration.

**Guidelines: Removing an AD Forest** You cannot remove an AD-forest configuration if it contains any child domains or tree domains, or if it is part of a forest-to-forest trust. You can manually remove all of the forest's child domains (with **no child-domain**) and tree domains (**no tree-domain**), or an **active-directory update forest** operation may automatically remove all of them. To remove any forest trust, use **no active-directory forest-trust**.

After the last child domain, tree domain, an/or trust is removed, you can use **no active-directory-forest**.

---

◆ **Note**

*You cannot remove an AD forest if any CIFS service is joined to its root domain (see [domain-join](#)). From *gbl-cifs* mode, use the **no cifs** command to remove CIFS service, then remove the forest.*

**Samples** `bstnA(gbl)# active-directory-forest sierra`  
`bstnA(gbl-forest[sierra])# ...`  
creates a forest named "sierra."

`bstnA(gbl)# no active-directory-forest ADtrial`  
`bstnA(gbl)# ...`  
removes a forest named "ADtrial."

# active-directory forest-trust

**Purpose** Windows 2003 servers can support a two-way trust between AD forests. Clients from one forest can access CIFS services in the other, trusted, forest. You can use the `active-directory forest-trust` command to reflect this trust relationship in the ARX configuration.

Use the `no` form of the command to remove the forest-to-forest trust between two forests.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `active-directory forest-trust forest-1 forest-2`  
`no active-directory forest-trust forest-1 forest-2`

*forest-1* (1-256 characters) is one of the two forests in the trust relationship. This must have a Windows 2003+ server as its [forest-root](#); earlier versions of Windows do not support forest-to-forest trusts.

*forest-2* (1-256 characters) is the other forest in the trust relationship, with the same restrictions as above.

**Default(s)** None

**Guidelines** This command is unnecessary if you use [kerberos auto-realm-traversal](#).

Both AD forests must be configured as [active-directory-forests](#) on the ARX, must have Windows 2003+ DCs as their [forest-roots](#), and must have a forest-function level of Windows 2003+ for this command to succeed. An error message explains any such configuration errors, and the command fails.

You can use the [active-directory update seed-domain](#) command to automatically discover an AD forest in your network and add it to the ARX configuration.

The forest-to-forest trust must exist externally, at the DCs, before you use this command to record the trust in the ARX configuration.

This records a two-way trust between the two forests. Clients from *forest-1* can access CIFS services in *forest-2*, and clients in *forest-2* can also access CIFS services in *forest-1*.

The forest-to-forest trust is direct, not transitive. Suppose a trust existed between forest A and forest B, and another trust existed between forest B and forest C. This does not imply that a client in forest A can access a CIFS service in forest C. A new trust must be established between forests A and C before the clients in one forest can access any services in the other. This reflects the forest-to-forest-trust behavior in Windows servers.

Because all forest trusts are direct, at least one CIFS service (see [cifs](#)) must be configured in one of the forests (*forest-1* or *forest-2*) for the trust to be relevant.

**Guidelines: Selective Authentication** If any of the forest trusts in the Windows network use “Selective Authentication,” the ARX must use a special algorithm to support clients in those forests. Use the [kerberos auto-realm-traversal](#) command to support remote forests with “Selective Authentication” set. As mentioned above, the [kerberos auto-realm-traversal](#) command makes the current command unnecessary; it enables automatic discovery of all trust relationships.

**Samples** `bstnA(gbl)# active-directory forest-trust medarch.org ri.com`  
establishes a two-way trust between two AD forests, ‘medarcv’ and ‘ri.com.’

`bstnA(gbl)# no active-directory forest-trust medarch.org ri.com`  
removes the above trust relationship. After this command, clients in the ‘ri.com’ forest can no-longer access any CIFS service in the ‘medarcv’ forest, nor can clients in ‘medarcv’ access services in ‘ri.com.’

**Related Commands** [active-directory update seed-domain](#)

[kerberos auto-realm-traversal](#)  
[show active-directory](#)  
[show active-directory status](#)

---

# active-directory update forest

**Purpose** A CIFS front-end service must understand the Active-Directory (AD) hierarchy in its network. That is, the CIFS service must know where to find the correct DC for each domain in the AD forest. The ARX database requires a full representation of the AD forest, with the IP addresses of at least one DC per domain.

If the actual forest changes, you can use the `active-directory update forest` command to discover the changes and add them to the ARX configuration.

**Mode** priv-exec

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `active-directory update forest forest-root proxy-user proxy  
[domain-controllers max-dcs] [site-name site]  
[verbose] [tentative]`

*forest-root* (1-255 characters) is the name of the `forest-root` domain. This is often the name of the AD-forest itself, too.

*proxy* (1-32 characters) is a `proxy-user` with credentials for accessing the root domain's DC(s). The ARX queries the DC for the names of other domains in the same AD forest.

*max-dcs* (optional, 1-100) sets a maximum number of DCs used in each domain. The ARX queries its DNS server to discover all the DCs in each domain; if the DNS server returns more DCs than *max-dcs*, the ARX takes the top DCs from the DNS list. The ARX uses the order returned from DNS.

*site* (optional, 1-64 characters) identifies the AD site for the ARX. This name is defined on a DC with the `Active Directory Sites and Services` plugin. The site name is case insensitive, so "portland" and "PORTLAND" are equivalent. If you omit this, the ARX software uses the AD site configured for the `ip proxy-address` subnet. Use this option if the AD's site configuration does not include the proxy-IP subnet.

*verbose* (optional) causes the command to show the results of the forest discovery as it progresses.

*tentative* (optional) makes the ARX perform the AD-forest discovery without creating the actual `active-directory-forest` configuration.

**Default(s)** *max-dcs* - all DCs returned from each DNS query.

*site* - the AD site configured on the external Active Directory for the proxy-IP subnet. This default requires that the proxy-IP subnet is defined in the AD; you can add the subnet on a DC with the `Active Directory Sites and Services` plugin.

**Guidelines** You can only use this command for an AD forest that is already configured on the ARX. To automatically discover an AD forest and add it to the ARX configuration, use the [active-directory update seed-domain](#) command. You can also use [active-directory-forest](#) to manually add a forest to the ARX configuration, or to manually edit an existing forest's configuration.

The ARX uses a DNS query to find the DC(s) in this domain, then queries one of the DCs for the other domains in the forest. The DNS server that you use must be able to translate for all DCs in the target forest. Use the [ip name-server](#) command to add a DNS server to the ARX configuration.

The AD-update operation creates a report named "active-directory-forest\_name.rpt," where *forest\_name* is the forest that you identified in the command. The CLI displays the name of the report after you issue the command. Use [show reports type AdUp](#) to list all AD-update reports. To follow the progress of the AD-update operation, you can use [tail reports report-name follow](#). Use [show reports report-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the [copy](#) or [delete](#) commands. If you want to truncate the report before it finishes, use the [truncate-report](#) command. See [Figure 18.1 on page 18-9](#) for a sample report.

Use the [show active-directory](#) command to show the configuration of the AD forest, as recorded on the ARX. To see the current state of all DCs in the forest, use the [show active-directory status](#) command.

**Guidelines: Domain Types** The report and the show commands all identify a domain type for each of the forest's domains. The update process categorizes all new domains as it finds them.

Domains in an AD forest have parent-child relationships based on their names. For example, the domain, "myorg.org," can have a child domain named "mygroup.myorg.org." In this relationship, "myorg.org" is called the *forest-root* domain and "mygroup.myorg.org" is a *child domain*.

An AD forest can also support trees that are outside the forest root's tree. These are domains with two-way-transitive-trust relationships with one or more domains in the root tree, but their domain names are entirely different. They are called *tree domains*. To continue the above example, a tree domain named "acme.com" may also be in the AD forest, and it may have a child domain named "coyote.acme.com."

**Guidelines: Dynamic DNS** Kerberos authentication requires that the forest's DNS servers have up-to-date mappings of the ARX-CIFS services and their IP addresses. To facilitate DNS updates as the ARX-CIFS services are added and removed, you can use the [gbl-forest name-server](#) command to identify a dynamic-DNS server for each domain in the forest. The AD-update process does not discover dynamic-DNS servers.

In many cases, the DC itself can also double as the name server for its domain.

**Guidelines: Trusts Between Forests** For AD forests with two-way-trust relationships, where clients from one forest are allowed to access CIFS services from the other forest, you can use the [kerberos auto-realm-traversal](#) command to automatically discover all such trust relationships. Alternatively, you can use the [active-directory forest-trust](#) command to declare a forest-to-forest trust relationship in the ARX configuration.

**Samples** bstnA# active-directory update forest wells.me.org proxy-user ny\_admin

Report File : active-directory-wells.me.org.rpt

updates an AD forest named “wells.me.org” and adds the forest to the ARX configuration. See [Figure 18.1](#) for a sample report.

bstnA# active-directory update forest vt.com proxy-user ny\_admin tentative

Report File : active-directory-VT.COM.rpt

performs a tentative update of the “vt.com” forest. This re-discovers the forest without changing the ARX configuration. Details about the forest discovery appear in the AD-update report.

# child-domain

**Purpose** Use the `child-domain` command to manually add a child domain (or one of its DCs) to an Active Directory forest.

If this domain has no children of its own, you can use `no child-domain` to remove it. You can also use `no child-domain` to remove a redundant DC from the child domain's configuration.

**Mode** gbl-forest

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `child-domain domain-name dc [preferred]`  
`no child-domain domain-name dc`

*domain-name* (1-256 characters) is the child domain name. This must be in the same domain namespace as its parent domain; for example, if the parent domain is "nonprofit.org," this child domain could be "mycharity.nonprofit.org."

*dc* is the IP address (for example, 192.168.25.56) of the domain controller (DC) for this child domain. If redundant DCs are hosting the domain, repeat this command (using the same *domain-name*) with the address of the redundant *dc*.

**preferred** (optional) declares that you prefer to use this DC over others in the same domain. Whenever the ARX Kerberos process chooses from multiple DCs in the same domain, it chooses from the DCs labeled "preferred" first.

**Guidelines** This command may not be necessary if you use [active-directory update seed-domain](#) to automatically discover all child domains in the AD forest.

A child domain must have a parent, which must be the forest root ([forest-root](#)), a tree domain ([tree-domain](#)), or another child domain. As stated earlier, the child-domain name must begin with the name of its parent domain.

A child domain can be the parent to other child domains.

Redundant DCs may manage a child domain. Re-use the `child-domain` command (with the same domain name) for each redundant DC. If you prefer to use one or more DCs in the domain over the others, use the **preferred** flag to identify those DCs. The Kerberos process selects its active DCs from the preferred list. The process only stops using a DC if its connection fails; the [kerberos health-check threshold](#) command selects a timeout threshold for DC connections. The Kerberos process does not choose any DC outside the preferred list unless all of the preferred DCs have timed out. You can use [show active-directory status](#) to see which DCs are currently active for each domain.

To remove a DC from the preferred list, you can re-run the `child-domain` command without the optional **preferred** flag. You can use this flag to change the active DC at any time.

There are two circumstances under which you can use `no child-domain`: the domain has no child domains under it, or the domain has one or more redundant DCs configured and you want to remove one of them.

**Samples** `bstnA(gbl-forest[sierra])# child-domain ne.sierra.acopia.com 10.5.2.1`  
adds the 'ne.siera.acopia.com' child domain to the 'sierra' forest.

`bstnA(gbl-forest[sierra])# child-domain ne.sierra.acopia.com 10.5.2.14`  
**preferred**

adds another DC to the 'ne.siera.acopia.com' domain, and declares it "preferred."  
The ARX attempts to use this DC before it uses the one from the previous example.

`bstnA(gbl-forest[sierra])# child-domain ne.sierra.acopia.com 10.5.2.14`  
takes the DC off of the "preferred" list for the 'ne.siera.acopia.com' domain. If there are no other preferred DCs for this domain, the ARX selects a DC from the non-preferred list (10.5.2.1 or 10.5.2.14, from these examples).

**Related Commands** [active-directory-forest](#)  
[active-directory update seed-domain](#)  
[kerberos health-check threshold](#)  
[domain-join](#)  
[forest-root](#)  
[show active-directory](#)  
[tree-domain](#)

---

# forest-root

**Purpose** Use the `forest-root` command to identify the forest-root domain (or one of its domain controllers) in the Active-Directory forest.

Use the `no` form of the command to remove the forest root, or one of the redundant domain controllers (DCs) that manages it.

**Mode** gbl-forest

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `forest-root domain-name dc [preferred]`  
`no forest-root domain-name dc`

*domain-name* (1-256 characters) is the domain name for the forest root.

*dc* is the IP address (for example, 192.168.25.56) of the forest root's DC. If redundant DCs are hosting the root domain, repeat this command (using the same *domain-name*) with the address of each redundant *dc*.

**preferred** (optional) declares that you prefer to use this DC over others in the same domain. Whenever the ARX Kerberos process chooses from multiple DCs in the same domain, it chooses from the DCs labeled "preferred" first.

**Default(s)** None

**Guidelines** This command may not be necessary if you use [active-directory update seed-domain](#) to automatically discover all domains in the AD forest.

Adding a forest root is the second step in manually creating an Active Directory forest. The `forest-root` command identifies the root domain for the forest, and one DC that manages the domain. If redundant DCs manage the root domain, you can use the command once for each DC.

An AD forest requires one forest root.

You can use [child-domain](#) to manually add one or more child domains to the forest root. The parent/child relationship between domains is established by their names: if "mycountry.gov" is the root domain, all of its child domains must reside in that domain (for example, "mystate.mycountry.gov" or "myprovince.mycountry.gov", but not "otherstate.org").

To add a disjoint tree of domains, use the [tree-domain](#) command. This is a tree of domains that is outside the root domain, but has a trust relationship with the domains in the forest root's tree. Just as with the forest root, you can use the [child-domain](#) command to add child domains to any tree domain.

If multiple DCs are configured to manage the forest root, you can use `no forest-root` to remove one of them at any time. Otherwise, the `no forest-root` command removes the entire root domain. To remove the forest-root domain, it cannot have any child domains, no CIFS services can be joined to the domain (through [domain-join](#)), and there can be no forest-trust relationships between this forest and any other forest (using `no active-directory forest-trust`).

**Guidelines: Choosing the Active DC**

If redundant DCs manage a domain, you can choose the DC(s) that you prefer for active use. Re-use the `forest-root` command (with the same domain name) for each redundant DC. You can use the optional `preferred` flag to identify preferred DCs. The Kerberos process uses DCs from the preferred list whenever possible. The process only stops using a DC if its connection times out; the `kerberos health-check threshold` command selects the timeout threshold. The Kerberos process does not choose any DC outside the preferred list unless all of the preferred DCs have timed out. You can use `show active-directory status` to see which DCs are currently active for each domain, including the forest-root domain.

To remove a DC from the preferred list, you can re-run the `forest-root` command without the optional `preferred` flag. You can use this flag to change the active DC at any time.

**Samples**

```
bstnA(gbl-forest[siera])# forest-root siera.acopia.com 10.5.1.23 preferred
```

sets the forest-root domain to 'siera.acopia.com,' and declares the DC at 10.5.1.23 to be preferred over other DCs in the same domain.

```
bstnA(gbl-forest[siera])# forest-root siera.acopia.com 10.5.1.23
```

re-sets the forest root, but removes the DC from the "preferred" list.

## ip address (gbl-ntlm-auth-srv)

**Purpose** *This command is relevant to an NTLM Secure Agent, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI mode and command.*

At an installation that uses NTLM or NTLMv2 with unconstrained delegation, the ARX uses the *Secure Agent* as an NTLM proxy. You install the Secure-Agent software on a Windows DC (domain controller). When a client accesses CIFS on the ARX, the switch forwards the NTLM-authentication request to the Secure Agent. The Secure Agent accesses the password database on the Windows DC, and it tells the ARX whether or not the authentication succeeded.

Use this command to specify the IP address of the Windows DC where the ARX Secure Agent is installed

For multiple domains, enter the IP address of each DC that hosts an instance of Secure Agent.

**Mode** gbl-ntlm-auth-srv

**Security Role(s)** crypto-officer

**Syntax** **ip address** *server-address*  
**no ip address**

*server-address* (0.0.0.0-255.255.255.255) is the IP address of the Secure Agent's DC.

Use the **no** form of the command to remove the IP address/host.

**Default(s)** None

**Guidelines: Using Constrained Delegation Instead of a Secure Agent** As mentioned above, Secure Agents (and this command) are unnecessary if all of your CIFS services use constrained delegation. Constrained delegation is implemented at a local DC. You can use the [probe delegate-to](#) command to retrieve some necessary configuration information to set up constrained delegation for your CIFS services.

For sites where some DCs are older than Windows Server 2003 (which introduced constrained delegation), this CLI mode and command are required for NTLM support.

**Guidelines: Running this Command** ARX Secure Agent software is installed on a Windows DC. You can install the Secure Agent on multiple DCs to support NTLM/NTLMv2 authentication for multiple domains.

Use this command to specify the IP address of the DC that runs an instance of Secure Agent. You can use the [port](#) command to specify the port at which the Secure Agent listens, assuming this port was also changed at the Secure Agent interface. See the *ARX Secure Agent Installation Guide* for more information about the Secure Agent.

Ensure there is a network link between the switch and each Windows domain controller that hosts an instance of Secure Agent.

**Sample**

```
gffstnA(gbl)# ntlm-auth-server ggh-dc
gffstnA(gbl-ntlm-auth-srv[ggh-dc])# ip address 192.168.25.109
```

specifies the IP address of the DC where the "ggh-dc" agent runs.

**Related Commands** [ntlm-auth-server](#)  
[port](#)  
[show ntlm-auth-server](#)

---

# kerberos auto-realm-traversal

**Purpose** On a Windows domain controller (DC), you can configure a forest-to-forest trust with *Selective Authentication*, where you list the clients in Forest A who have access privileges in Forest B. If the ARX is in Forest B, these privileged clients cannot use its services unless you enable *auto-realm traversal* on the ARX. Auto-realm traversal is an ARX algorithm that supports selective authentication. Auto-realm traversal also allows automatic support of all forest-to-forest trusts in your Active Directory, without explicitly stating them in the ARX configuration. This is a recommended feature.

You can use the `no kerberos auto-realm-traversal` command to stop supporting this feature, and make it impossible for clients to authenticate from an external forest with a “Selective Authentication” policy. This is not generally advisable, and should only be done on the advice of F5 Support.

Use the affirmative form of the command to return to the default Kerberos algorithm. This supports all Kerberos clients, including clients on the other side of a selective-authentication trust, and it automatically supports all forest-to-forest trusts.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `no kerberos auto-realm-traversal`  
`kerberos auto-realm-traversal`

**Default(s)** `kerberos auto-realm-traversal`

**Guidelines** This is a system-wide parameter; the Kerberos software uses the same realm-traversal algorithm for all clients. If you use the default setting, you do not need to explicitly declare any forest-to-forest trusts with the [active-directory forest-trust](#) command. This is recommended.

If you choose to disable this feature, you can use the [active-directory forest-trust](#) command to inform the ARX of each forest-to-forest trust in your network. However, clients cannot connect to the ARX through a forest-to-forest trust with selective authentication.

**Sample** `bstnA(gbl)# kerberos auto-realm-traversal`  
supports clients on the other side of a forest-to-forest trust with “Selective Authentication” enabled.

**Related Commands** [active-directory forest-trust](#)

## kerberos health-check threshold

**Purpose** The Kerberos software regularly sends a simple LDAP query to all of the DCs in its AD forest, and times the response from each DC. If a DC takes too long to respond, the Kerberos software declares it “offline” and sends an SNMP trap. You can use the `kerberos health-check threshold` command to determine the maximum allowable response time from any DC.

Use the `no` form of the command to return to the default response time.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `kerberos health-check threshold milliseconds`  
`no kerberos health-check threshold`

*milliseconds* (optional 500-10,000) is the maximum amount of time allowed for a DC response.

**Default(s)** 2,000 (2 seconds)

**Guidelines** This is a system-wide parameter; the maximum time applies to all DCs in all AD forests. For a complete list of all of these DCs, use the [show active-directory](#) command.

The LDAP query tests the DC’s ability to perform lookups in the AD database. This is designed as an unobtrusive verification of the DC’s basic functions.

The Kerberos process sends an LDAP request every 60 seconds. After the Kerberos software declares a DC offline, it continues to send the LDAP request at the same rate; if the DC responds within the allotted time, the Kerberos process declares it “online” again. The [show active-directory status](#) command displays the current state of all DCs known to the ARX.

**Samples** `prt1ndA(gbl)# kerberos health-check threshold 5000`  
sets a 5-second threshold for DC responses.

`stoweA(gbl)# no kerberos health-check threshold`  
sets the threshold to the default on the “stoweA” system.

**Related Commands** [active-directory update seed-domain](#)  
[show active-directory](#)  
[show active-directory status](#)

---

## name-server

**Purpose** Kerberos authentication requires accurate DNS configuration for all CIFS services. To facilitate this, CIFS services can use *dynamic DNS* to register their host names with your DNS servers and update those servers whenever their hostname-to-IP mapping changes. Use the `name-server` command to identify a dynamic-DNS name server. You can use `no name-server` to remove a name server.

**Mode** gbl-forest

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `name-server domain-name ip-address`  
`no name-server domain-name ip-address`

*domain-name* (1-255 characters) is the name of the AD domain that is supported by the name server, below.

*ip-address* is the IP address of the name server. This is frequently the same as the DC that manages the domain, identified with [forest-root](#), [child-domain](#), or [tree-domain](#).

**Default(s)** None

**Guidelines** Basic Domain Name Service (DNS) is defined in two RFCs, 1034 and 1035. The ARX also supports the Microsoft-specific authentication extensions specified in RFC 3645.

We recommend that every domain in the AD forest has at least one name server configured. (The [show active-directory](#) command shows all domains in an AD forest.) If a domain's DNS records do not correctly identify a front-end CIFS service, the domain's Windows clients cannot use Kerberos to authenticate with it.

You can use this command more than once to identify multiple name servers for the same AD domain. A CIFS service in that domain tries the first-configured service, then the second, and so forth until it successfully registers its IP address in an "A" record. After it succeeds, it stops registering; the external DNS servers are presumed to duplicate their "A" records independently, as configured by the DNS administrator.

From gbl-cifs mode, use [dynamic-dns](#) to DNS-register the front-end CIFS service. A CIFS service only registers with a name server when it is enabled (with [enable \(gbl-cifs, gbl-nfs\)](#)).

**Samples** `bstnA(gbl-forest[siera])# name-server siera.acopia.com 10.5.1.23`  
`bstnA(gbl-forest[siera])# name-server siera.acopia.com 10.5.1.29`  
identifies two dynamic-DNS servers for the 'siera.acopia.com' domain.

`bstnA(gbl-forest[siera])# no name-server siera.acopia.com 10.5.1.29`  
removes one name server from the 'siera.acopia.com' domain.

**Related Commands** [active-directory-forest](#)  
[show active-directory](#)  
[forest-root](#)  
[child-domain](#)  
[tree-domain](#)  
[dynamic-dns](#)

## ntlm-auth-db

**Purpose** *This command is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI command.*

Use this command to configure an NTLM authentication database. The NTLM authentication database contains a list of valid usernames/passwords (up to 10). If a client is in the database, the ARX can use preset credentials to authenticate user access to back-end CIFS filers and shares.

Use the `ntlm-auth-db` command to instantiate a new NTLM authentication database.

**Mode** `gbl`

**Security Role(s)** `crypto-officer`

**Syntax** `ntlm-auth-db name`  
`no ntlm-auth-db name`

*name* (1-64 characters) is a name that you choose for the Windows NTLM authentication demo database.

Use the `no` form of the command to remove an NTLM authentication database.

**Default(s)** `None`

**Guidelines: Using Constrained Delegation Instead of a Secure Agent** As mentioned above, this command is unnecessary if all of your CIFS services use constrained delegation. Constrained delegation is implemented at a local DC. You can use the [probe delegate-to](#) command to retrieve some necessary configuration information to set up constrained delegation for your CIFS services.

For sites where some DCs are older than Windows Server 2003 (which introduced constrained delegation), either this command or [ntlm-auth-server](#) is required for NTLM support.

**Guidelines: Running the Command** This command puts you into `gbl-ntlm-auth-db` mode, where you configure the NTLM demo database parameters. Use the [user \(gbl-ntlm-auth-db\)](#) command to configure up to 10 users/encrypted passwords associated with the NTLM authentication demo database. You need one valid username/password for each supported client (up to 10).

If you have more than one namespace that supports the same domain, you can assign the same database to both namespaces. Use the [ntlm-auth-db \(gbl-ns\)](#) command to assign an NTLM authentication database to a namespace.

If you remove an authentication database with the `no` form of the command, clients cannot access CIFS shares in a namespace that uses the database.

**Samples** `bstnA(gbl)# ntlm-auth-db MYDEMO`  
`bstnA(gbl-ntlm-auth-db[MYDEMO])#`  
creates a new NTLM authentication database, "MYDEMO."

`bstnA(gbl)# no ntlm-auth-db OLDDemo`  
removes an NTLM authentication database, "OLDDemo," from the switch.

**Related Commands** [ntlm-auth-db \(gbl-ns\)](#)  
[user \(gbl-ntlm-auth-db\)](#)

## ntlm-auth-server

**Purpose** *This command is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI command.*

The ARX Secure Agent can be separately installed on a Windows domain controller (DC). If a front-end CIFS service uses unconstrained delegation, it requires the Secure Agent to assist with NTLM and/or NTLMv2 authentication for its clients. (This command has no effect on Kerberos authentication.) Use the `ntlm-auth-server` command to begin configuring a Secure Agent server at the ARX.

Use the `no` form of the command to remove a Secure-Agent-server configuration from the switch.

**Mode** gbl

**Security Role(s)** crypto-officer

**Syntax** `ntlm-auth-server name`  
`no ntlm-auth-server name`

*name* (1-128 characters) is a name that you choose for the Secure Agent server. Create a Secure Agent server for each DC that hosts a Secure Agent.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before creating a new NTLM-server configuration object; enter `yes` to continue.

---

◆ **Note**

*If the front-end CIFS Service uses **constrained delegation**, introduced with Windows Server 2003, the Secure Agent (and this command) is unnecessary. An administrator with “Domain Administrator” privileges can go to the DC and configure constrained delegation for this CIFS service. You can use the [probe delegate-to](#) command to find all back-end filers behind a CIFS service, which the DC administrator adds to the CIFS service’s “delegate-to” list. Once the CIFS service is set up this way at the DC, the service’s clients can authenticate with NTLM, NTLMv2, and/or Kerberos.*

**Guidelines (Cont.)** For CIFS services with unconstrained delegation, one NTLM-server configuration object is required for each Secure Agent installed on each DC. This command creates a new NTLM server and places you in `ntlm-auth-server` mode, where you configure the Secure Agent server's attributes:

- Use the `ip address (gbl-ntlm-auth-srv)` command to enter the IP address of the DC running the Secure Agent.
- Use the `port` command to assign a port on which the Secure Agent listens for authentication requests from the switch.
- Use the `windows-domain (gbl-ntlm-auth-srv)` command to associate a domain name with this NTLM authentication server. This is a Windows domain that is managed by the server's DC host. Use the exact domain name that clients use for authentication.
- Use the `password` command to provide the password for accessing the Secure Agent authentication server.

After you configure the server's attributes, you assign it to one or more namespaces. Use the `ntlm-auth-server (gbl-ns)` command in `gbl-ns` mode to assign an NTLM-authentication server to a namespace. The Secure Agent assists the namespace with NTLM/NTLMv2 authentication for its CIFS clients. You can assign multiple NTLM-authentication servers to a single namespace, and you can assign a single NTLM-authentication server to multiple namespaces.

If you have redundant DCs for a given Windows Domain, we recommend installing a Secure Agent on all of them and using this command to add each of them to the ARX configuration. If you assign more than one to a namespace, the namespace software tries each of them until it successfully connects. The namespace software starts with the Secure Agent running the highest software revision.

If you remove a Secure Agent server with the `no` form of the command, NTLM/NTLMv2 clients cannot access CIFS shares in a namespace that uses this Secure Agent instance. Kerberos authentication is unaffected, though a fall-back to any version of NTLM fails if there is no Secure Agent for the requested domain.

The namespace's `proxy-user` (used for autonomous volume operations, such as import and file migrations) does not require an NTLM server to authenticate.

For more information about Secure Agent, see the *ARX Secure Agent Installation Guide*.

**Samples** `gffstnA(gbl)# ntlm-auth-server ggh-dc`

This will create a new NTLM Server.

```
Create NTLM Server 'ggh-dc'? [yes/no] yes
gffstnA(gbl-ntlm-auth-srv[ggh-dc])#
 instantiates a Secure Agent server, "server1."
```

```
bstnA(gbl)# no ntlm-auth-server dc1
```

removes the Secure Agent server, "dc1," from the ARX configuration.

**Related Commands** `show ntlm-auth-server`  
`ip address (gbl-ntlm-auth-srv)`  
`port`  
`windows-domain (gbl-ntlm-auth-srv)`  
`password`

## password

**Purpose** *This command is relevant to an NTLM Secure Agent, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI mode and command.*

At an installation that uses NTLM or NTLMv2 authentication with unconstrained delegation, the ARX uses the *Secure Agent* as an NTLM proxy. Use this command to enter a password to be shared by the Secure Agent and the ARX. The Secure Agent and the ARX use this password to verify each other's identity when they first establish a TCP connection.

**Mode** gbl-ntlm-auth-srv

**Security Role(s)** crypto-officer

**Syntax** password

**Default(s)** None

**Guidelines: Using Constrained Delegation Instead of a Secure Agent** As mentioned above, Secure Agents (and this command) are unnecessary if all of your CIFS services use constrained delegation. Constrained delegation is implemented at a local DC. You can use the [probe delegate-to](#) command to retrieve some necessary configuration information to set up constrained delegation for your CIFS services.

For sites where some DCs are older than Windows Server 2003 (which introduced constrained delegation), this CLI mode and command are required for NTLM support.

**Guidelines: Running the Command** The CLI prompts you for the password, then prompts again to re-enter the password. Enter 4-64 characters. The password does not appear in the `show running/global-config` output as plain text, but as a base64-encoded password.

The password you enter in this command must match the password configured at the ARX Secure Agent.

The switch uses Secure Agent software to assist in CIFS authentication requests received from clients to back-end CIFS storage devices. See the *ARX Secure Agent Installation Guide* for information about installing and managing Secure Agent software.

**Sample**  
gffstnA(gbl)# ntlm-auth-server ggh-dc  
gffstnA(gbl-ntlm-auth-srv[ggh-dc])# password  
Password: \*\*\*\*\*  
Validate Password: \*\*\*\*\*  
gffstnA(gbl-ntlm-auth-srv[ggh-dc])#

**Related Commands** [ntlm-auth-server](#)  
[show ntlm-auth-server](#)

---

## permit (gbl-mgmt-auth)

**Purpose** A Windows-management-authorization (WMA) group is a list of Windows clients who can use Windows-management applications (such as MMC or snapshots) in one or more namespaces. The **permit** command establishes a permissible management action for the current WMA group.

Use **no permit** to remove a permission from the group.

**Mode** gbl-mgmt-auth

**Security Role(s)** crypto-officer

**Syntax** **permit** {share | session | open-file | snapshot | all} {monitor | any}

**no permit** {share | session | open-file | snapshot | all}

**share | session | open-file | snapshot | all** chooses the object of this permission:

**share** selects CIFS-service shares, as well as non-shared volumes that are eligible to be added as CIFS shares. With **any** permissions (see below), members of this group can add and delete shares, too.

**session** represents client sessions that are currently connected to the CIFS service. A member client can potentially see all other client sessions if the group has the **monitor** permission (below). With the **any** permission, the members can also potentially disconnect other clients.

**open-file** chooses open files. If this has **monitor** permission, a group member can see these files; with **any** permission, a member can close files, too.

**snapshot** selects the directory for accessing a volume's snapshots. WMA group members, when they access the volume through CIFS, can only see the snapshot directory if you set the **monitor** permission for this. The **any** permission has the same effect.

**all** selects all of the above.

**monitor | any** shows what the member clients can do with the object(s):

**monitor** allows read-only access. This limits group members to listing (not changing) a CIFS service's shares, sessions, open files and/or snapshots.

**any** allows read-write access, so that member clients add, delete, close, and/or shut down the objects as appropriate. This has no additional affect on snapshots, which can only be monitored.

**Default(s)** no permit share  
no permit session  
no permit open-file

**Guidelines** Depending on the management permissions for the group, its members may be able to add new shares, view open files, and/or disconnect other client sessions. Use this command to set the specific permissions for this group; invoke the command multiple times to establish different permission levels for each object. Use the [user \(gbl-mgmt-auth\)](#) command to add Windows clients to the group.

Use the [show windows-mgmt-auth](#) command to display the configuration for a WMA group.

To apply a WMA group to a namespace, use [windows-mgmt-auth \(gbl-ns\)](#). You can apply multiple groups to the same namespace. Any CIFS service in front of this namespace uses these WMA groups if it has remote management/browsing enabled. From gbl-cifs mode, use [browsing](#) to enable remote management/browsing for a CIFS service.

The WMA group's members only see the results of this command if they connect *after* you invoke it.

**Guidelines:** MMC software finds all session connections to a share before it deletes the share. The MMC “delete share” operation therefore fails with an error if it does not have permission to find the share's session connections. Use this extra command to allow MMC to find session connections:

**permit session monitor**

(The **permit session all** command also works for MMC.)

This is in addition to the following command, which permits the client to remove the share:

**permit share all**

**Samples** `bstnA(gbl-mgmt-auth[fullAccess])# permit all any`  
allows the “fullAccess” group to perform any management actions on shares, open files, and client sessions.

`bstnA(gbl-mgmt-auth[readOnly])# permit share monitor`

`bstnA(gbl-mgmt-auth[readOnly])# permit session monitor`

permits members of the “readOnly” group to see all shares and client sessions, but not to change them in any way.

`bstnA(gbl-mgmt-auth[snapViewers])# permit snapshot monitor`

permits members of the “snapViewers” group to see the snapshot directory through CIFS.

`bstnA(gbl-mgmt-auth[fullAccess])# no permit open-file`

disqualifies the “fullAccess” group from viewing or changing open files though MMC or similar applications.

**Related Commands** [windows-mgmt-auth](#)  
[user \(gbl-mgmt-auth\)](#)  
[show windows-mgmt-auth](#)  
[windows-mgmt-auth \(gbl-ns\)](#)  
[browsing](#)

---

# port

**Purpose** *This command is relevant to an NTLM Secure Agent, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI mode and command.*

At an installation that uses NTLM or NTLMv2 authentication with unconstrained delegation, the ARX uses the *Secure Agent* as an NTLM proxy. Use this command to enter the TCP port (number) on which Secure Agent listens for authentication requests from the switch.

Use the **no** form of the command to remove the current port number.

**Mode** gbl-ntlm-auth-srv

**Security Role(s)** crypto-officer

**Syntax** **port** *port*  
**no** *port*

*port* (optional; 1-65535) is the port number on which Secure Agent listens for authentication requests from the switch.

**Default(s)** 25805

**Guidelines: Using Constrained Delegation Instead of a Secure Agent** As mentioned above, Secure Agents (and this command) are unnecessary if all of your CIFS services use constrained delegation. Constrained delegation is implemented at a local DC. You can use the [probe delegate-to](#) command to retrieve some necessary configuration information to set up constrained delegation for your CIFS services.

For sites where some DCs are older than Windows Server 2003 (which introduced constrained delegation), this CLI mode and command are required for NTLM support.

**Guidelines: Running the Command** The Secure Agent server uses the specified port for NTLM-authentication transactions with the switch. The port number must match the port number specified when the Secure Agent software was installed on a Windows Domain Controller. If you do not enter a port number, the default port is used. See the *ARX Secure Agent Installation Guide* for more information.

**Sample** gffstnA(gbl)# ntlm-auth-server ggh-dc  
gffstnA(gbl-ntlm-auth-srv[ggh-dc])# port 25805  
sets the Secure Agent server's port number to 25805.

**Related Commands** [ntlm-auth-server](#)  
[ip address \(gbl-ntlm-auth-srv\)](#)

## show ntlm-auth-db

**Purpose** *This command is relevant to an NTLM authentication database, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation.*

Use this command to display the configured NTLM-authentication demo databases.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ntlm-auth-db [name]`

*name* (1-64 characters) is the name of an NTLM authentication demo database.

If no name is specified, this command shows names for all configured NTLM-authentication demo databases.

**Guidelines** With the `name` argument, the command shows the username(s) and namespace(s) that use this database.

Use the [user \(gbl-ntlm-auth-db\)](#) command to add a user to the database.

Use the [ntlm-auth-db \(gbl-ns\)](#) command to assign the database to a namespace.

**Sample** `bstnA> show ntlm-auth-db`

```
Name

ntlmMap2
ntlmMap3
```

`bstnA> show ntlm-auth-db ntlmMap2`

```
Name

ntlmMap2

Users

techspecialist

Mapped to the Following Namespaces

cifsNamespace1
```

**Related Commands** [ntlm-auth-db](#)  
[ntlm-auth-db \(gbl-ns\)](#)  
[user \(gbl-ntlm-auth-db\)](#)

---

## show ntlm-auth-server

**Purpose** *This command is relevant to an NTLM authentication server, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation.*

At an installation that does not support constrained delegation, the ARX uses the *Secure Agent* as an NTLM/NTLMv2 proxy. Use the `show ntlm-auth-server` command to display the configuration and statistics from one or more configured Secure Agent servers.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show ntlm-auth-server [name] [detailed]`

*name* (optional, 1-128 characters) is the name of a Secure Agent server instance. If no name is specified, this command shows statistics for all configured Secure Agent servers.

**detailed** (optional) generates detailed output, with success and failure counts from all current connections to the Secure Agent(s).

**Guidelines: Using  
Constrained  
Delegation Instead of  
a Secure Agent**

As mentioned above, Secure Agents (and this command) are unnecessary if all of your CIFS services use constrained delegation. Constrained delegation is implemented at a local DC. You can use the [probe delegate-to](#) command to retrieve some necessary configuration information to set up constrained delegation for your CIFS services.

For sites that can follow this recommendation, you can use [show statistics domain-controller](#) to retrieve NTLM-authentication statistics.

For sites where some DCs are older than Windows Server 2003 (which introduced constrained delegation), a Secure Agent is required for NTLM support and this command is relevant.

**Guidelines: Summary  
Output**

For the summary output, this command includes the following categories:

**Name** is the name of this Secure Agent server instance, as configured with the [ntlm-auth-server](#) command.

**Version** identifies the Software Release of the Secure Agent software.

**Server** is the IP address of the Secure Agent server host system. If this is incorrect, you can use the [ip address \(gbl-ntlm-auth-srv\)](#) command to change it.

**Domain Name** is the associated Windows Domain. If this is incorrect, you can use the [windows-domain \(gbl-ntlm-auth-srv\)](#) command to correct it.

**Pre-Win2k Domain** is the “short” name of the above domain, for domains that existed before the release of Windows 2000. As above, you can use the [windows-domain \(gbl-ntlm-auth-srv\)](#) command to correct this in the ARX database.

**Capabilities** is “NTLM,” “NTLM, NTLMv2, Session Key,” or “Unknown.” The “Session Key” flag indicates that the Secure Agent can support SMB signing (see [cifs filer-signatures](#) and [signatures](#)).

**Status** is one of the following:

- **Reachable** is the status for a healthy Secure Agent.
- **Unreachable** indicates a connection problem. Check the connection to the Secure Agent with [show exports](#), [expect traceroute](#), and/or [ping](#).
- **Password Mismatch** means that the password configured at the ARX (with the [password](#) command) is different from the password configured in the Secure Agent’s management applet. The *ARX Secure Agent Installation Guide* explains how to reset the password at the Secure Agent’s management applet.
- If another error appears, contact F5 Support for analysis.

**Guidelines: Detailed Output**

The **detailed** keyword causes the command to download detailed statistics from the Secure Agent(s). These are high-level statistics followed by a table of counters for every current connection to a Secure Agent. If you selected all Secure Agents, a separate **SECURE AGENT STATISTICS** page appears for each of them. The high-level statistics include the following:

**Agent IP** is the IP address of the Secure Agent's host DC.

**Agent Port** is the TCP port where the Secure Agent is listening for ARX queries.

**Uptime** shows the amount of time since the last restart of the Secure Agent application.

**Current Connections** is the number of ARX systems currently connected to the Secure Agent.

**Failed connection attempts** and

**Successful connection attempts** summarize the connection statistics.

**Account Scan Interval** is the time between scans of the DC's SAM database, in seconds. The Secure Agent uses this scanned data to assist the ARX with its NTLM/NTLMv2 authentications.

**Software Version** is the release number for the Secure Agent software.

**Capabilities** is "NTLM," "NTLM, NTLMv2, Session Key," or "Unknown.," as above.

**Connection #1** lists specific details about the first connection to the server including the source IP address, bytes transmitted, successful or failed client authentications, and filer response generation statistics. The "client" in these statistics is an ARX (typically, the current ARX), and the **Source IP** in the output is the [ip proxy-address](#) that the ARX used to connect to the Secure Agent.

**Connection #2**, and any additional connections shown, list details specific to that connection to the server.

**Samples**

```
gffstnA> show ntlm-auth-server
```

lists all configured Secure Agent servers. See [Figure 18.2 on page 18-32](#) for sample output.

```
gffstnA> show ntlm-auth-server ggh-dc
```

shows high-levels statistics about one Secure Agent server, 'ggh-dc.' See [Figure 18.3 on page 18-32](#) for sample output.

```
gffstnA> show ntlm-auth-server detailed
```

shows detailed statistics about all Secure Agent servers. See [Figure 18.4 on page 18-32](#) for sample output.

## show windows-mgmt-auth

**Purpose** A Windows-management-authorization (WMA) group is a list of Windows clients with permissions to use Windows-management applications (such as MMC). Use this command to show the members and permissions for this type of group.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show windows-mgmt-auth [name]`

*name* (optional; 1-64 characters) is the name of a specific WMA group.

If no name is specified, this command shows all WMA groups.

**Guidelines** The output for this command shows the following information for each WMA group: Windows Authorization Policy is the name of the WMA group, specified in the [windows-mgmt-auth](#) command.

The user list appears next, as a table with one row per user:

User Name and

Domain Name describe one client in the group. Use [user \(gbl-mgmt-auth\)](#) to add or remove a client. If there is a pre-Windows 2000 name for the domain, it appears in the Domain Name field in parentheses.

The last table shows the management permissions for the group, one permission per row. Each row has two fields:

Managed Object is Share, Session, Open-file, Snapshot, or All. The permission (below) applies to this is the type of object.

Permitted Operation is “Monitor” or “Any.” “Monitor” means that WMA-group clients can view the Managed Objects (shares, client sessions, open-files, or snapshots). “Any” means that the clients can change them, too (except snapshots, which are always read-only). Use [permit \(gbl-mgmt-auth\)](#) to add or remove a permission.

**Samples** `bstnA> show windows-mgmt-auth`  
shows all WMA groups on this system. See [Figure 18.5](#) for sample output.

`bstnA> show windows-mgmt-auth fullAccess`  
shows one WMA group, “fullAccess.” See [Figure 18.6 on page 18-35](#) for sample output.

**Related Commands** [windows-mgmt-auth](#)  
[user \(gbl-mgmt-auth\)](#)  
[permit \(gbl-mgmt-auth\)](#)

```

## tree-domain

**Purpose** Some Active-Directory (AD) domains are outside the domain namespace, but have a trust relationship with domains in the forest. These are called *tree domains*. Use the `tree-domain` command to add a tree domain to the AD forest.

Use the `no` form of the command to remove a tree domain, or one of the redundant DCs that manages it.

**Mode** gbl-forest

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `tree-domain domain-name dc [preferred]`  
`no tree-domain domain-name dc`

*domain-name* (1-256 characters) is the tree domain name. This does not require any parent in the forest.

*dc* is the IP address (for example, 192.168.25.56) of the domain controller (DC) for the tree domain. If redundant DCs are hosting the domain, repeat this command (using the same *domain-name*) with the address of the redundant *dc*.

**preferred** (optional) declares that you prefer to use this DC over others in the same domain. Whenever the ARX Kerberos process chooses from multiple DCs in the same domain, it chooses from the DCs labeled “preferred” first.

**Default(s)** None.

**Guidelines** This command may not be necessary if you use [active-directory update seed-domain](#) to automatically discover all child domains in the AD forest. Before you use this command, use the above command (or [forest-root](#)) to add a root to the Active Directory forest.

The `tree-domain` command adds a disjoint tree to the forest, outside of the forest’s domain namespace. For example, if the forest has a root domain of “telco.com” with two child domains, “na.telco.com” and “asia.telco.com,” you could establish a tree domain outside the namespace, “myphone.org.” The tree domain is presumed to have a two-way-transitive-trust relationship with one of the domains in the root forest.

If redundant DCs manage the tree domain, re-use the `tree-domain` command (with the same Domain name) for each redundant DC. If you prefer to use one or more DCs in the domain over the others, use the **preferred** flag to identify those DCs. The Kerberos process uses the DC(s) from the preferred list as its active DC(s). The process only stops using a DC if its connection times out; the [kerberos health-check threshold](#) command selects the timeout threshold. The Kerberos process does not choose any DCs outside the preferred list unless all of the preferred DCs have timed out. You can use [show active-directory status](#) to see which DCs are currently active for each domain.

To remove a DC from the preferred list, you can re-run the `tree-domain` command without the optional **preferred** flag. You can use this flag to change the active DC at any time.

**Guidelines (Cont.)** You can use the [child-domain](#) command to add a child to this tree domain. The parent/child relationship is created through the domain names (“aparent.com” can be the parent to “achild.aparent.com”).

If the tree is managed by redundant DCs, you can use `no tree-domain` to remove one of them from the configuration. Otherwise, the “no” command removes the tree domain entirely; you must remove all of the tree’s child domains before you can do this.

**Samples** `bstnA(gbl-forest[medarch])# tree-domain ne.medarch.org 172.16.124.73 preferred`  
adds the ‘ne.medarch.org’ tree domain to a forest. This also declares this DC to be preferred over others in the same domain.

`bstnA(gbl-forest[medarch])# tree-domain ne.medarch.org 172.16.124.73`  
has the same effect as the previous example, but removes the DC from the “preferred” list.

**Related Commands** [active-directory-forest](#)  
[active-directory update seed-domain](#)  
[kerberos health-check threshold](#)  
[child-domain](#)  
[domain-join](#)  
[forest-root](#)  
[show virtual service](#)

## user (gbl-mgmt-auth)

**Purpose** A Windows-management-authorization (WMA) group is a list of Windows clients with permissions to use remote Windows-management applications, such as MMC. The `user` command adds a client to the current WMA group.

Use `no user` to remove a user from the group.

**Mode** gbl-mgmt-auth

**Security Role(s)** crypto-officer

**Syntax** `user name windows-domain fqdn [pre-win2k-name old-style-domain]`  
`no user name windows-domain domain-name`

*name* (1-64 characters) is a valid Windows user.

*domain-name* (1-64 characters) is the user's domain name, exactly as the client types it for authentications. We recommend using the fully-qualified domain name (FQDN) for this field. If the client uses the FQDN (such as "mygroup.org") to authenticate, they can use Kerberos; if the client uses the older NetBIOS name from the first part of the FQDN (such as "MYGROUP"), the client can only use some form of NTLM.

*old-style-domain* (optional, 1-15 bytes, no periods) is the legacy, NetBIOS name of the Windows domain, if it is different from the default (below). The default should suffice for most situations; this option should only rarely be necessary. Clients who authenticate with this pre-Windows 2000 name can also use MMC; for example, if the pre-Windows 2000 name is "GROUP" for the "mygroup.org" domain, an MMC client could authenticate as "GROUP/juser" or "mygroup.org/juser."

**Default(s)** *old-style-domain* - The old-style name discovered with [active-directory update seed-domain](#). If the old-style name was never discovered for this domain, the ARX uses the first part (before the first ".", up to 15 characters) of the FQDN in the *domain-name*.

**Guidelines** Depending on the management permissions for the group, they may be able to add new shares, view open files, and/or disconnect other client sessions. Use the [permit \(gbl-mgmt-auth\)](#) command to set the specific permissions for this group. Use this command multiple times to add multiple users to the group.

Use the [show windows-mgmt-auth](#) command to display the configuration for a WMA group.

To apply a WMA group to a namespace, use [windows-mgmt-auth \(gbl-ns\)](#). You can apply multiple groups to the same namespace. Use [browsing](#) to enable Windows management for a CIFS service.

**Samples** `bstnA(gbl-mgmt-auth[fullAccess])# user jquser windows-domain MEDARCH.ORG`

adds a user to the WMA group, "fullAccess."

`bstnA(gbl-mgmt-auth[readOnly])# no user test5 windows-domain MEDARCH.ORG`

removes a user from the "readOnly" group.

**Related Commands** [windows-mgmt-auth](#)  
[permit \(gbl-mgmt-auth\)](#)  
[show windows-mgmt-auth](#)  
[windows-mgmt-auth \(gbl-ns\)](#)  
[browsing](#)

## user (gbl-ntlm-auth-db)

**Purpose** *This command is relevant to an NTLM authentication database, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI mode and command.*

Use this command to enter up to 10 usernames and passwords associated with the NTLM authentication database. If a client entry is in the database, the ARX can use the preset credentials to authenticate connections for access to back-end CIFS filers.

**Mode** gbl-ntlm-auth-db

**Security Role(s)** crypto-officer

**Syntax** **user** *dbuser*  
**no** **user** *dbuser*

*dbuser* (1-64 characters) is one authorized Windows user.

**Default(s)** None

**Guidelines** The CLI prompts for the user's password twice. You need one valid username and password for each supported client (up to 10). Use the **no** form of the command to remove a user from the current database.

**Samples** `bstnA(gbl-ntlm-auth-db[MYDEMO])# user sales`  
Password: `*****`  
Validate Password: `*****`  
creates the user, "sales," associated with the MYDEMO database

`bstnA(gbl-ntlm-auth-db[MYDEMO])# no user sales`  
removes the user, "sales" associated with the "MYDEMO" database.

**Related Commands** [ntlm-auth-db](#)

---

## windows-domain (gbl-ntlm-auth-srv)

**Purpose** *This command is relevant to an NTLM Secure Agent, which is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI mode and command.*

At an installation that uses NTLM or NTLMv2 with unconstrained delegation, the ARX uses the *Secure Agent* as an NTLM proxy. Use this command to assign the domain name to a Secure Agent server.

Use the `no` form of the command to remove the domain name for this Secure Agent, thereby disabling it.

**Mode** gbl-ntlm-auth-srv

**Security Role(s)** crypto-officer

**Syntax** `windows-domain domain-name [pre-win2k-name old-style-domain]`  
`no windows-domain`

*domain-name* (1-64 characters) is the Windows Domain to which you assign a Secure Agent instance (authentication server). When a client authenticates to an ARX CIFS service, the client uses this Secure Agent if they use this domain name.

*old-style-domain* (optional, 1-15 characters, no periods) is the name of the legacy Windows domain, if it is different from the default (below). The default should suffice for most situations; this option should only rarely be necessary. Clients who authenticate with the pre-Windows 2000 name can also use this Secure Agent.

**Default(s)** *old-style-domain* - The old-style name discovered with [active-directory update seed-domain](#). If the old-style name was never discovered for this domain, the ARX assumes that the old-style name is the first part (before the first “.”, up to 15 characters) of the FQDN in the *domain-name*.

**Guidelines: Using Constrained Delegation Instead of a Secure Agent**

As mentioned above, Secure Agents (and this command) are unnecessary if all of your CIFS services use constrained delegation. Constrained delegation is implemented at a local DC. You can use the [probe delegate-to](#) command to retrieve some necessary configuration information to set up constrained delegation for your CIFS services.

For sites where some DCs are older than Windows Server 2003 (which introduced constrained delegation), this CLI mode and command are required for NTLM support.

**Guidelines: Running the Command**

The domain name is the Windows domain where the Secure Agent software is installed (for each domain controller that hosts Secure Agent).

Use the longest domain name that clients use for their authentications. For example, if clients authenticate with “porthos.musketeer.gov” domain as well as the shorter “porthos” name, you should create an authentication server for “porthos.musketeer.gov.” The ARX uses the single authentication-server object for the domain name and all shorter variations of the same domain name.

For domains with a completely-different pre-Win2k name, such as “GUARD3” as an the early name for “porthos,” use the `pre-win2k-name` option. The separate authentication server should use the same [ip address \(gbl-ntlm-auth-srv\)](#) to point to the same DC.

If you remove the domain name with the `no` form of this command, clients cannot access CIFS shares in a namespace that uses this instance of Secure Agent.

**Sample**

```
gffstnA(gbl)# ntlm-auth-server serverFQDN
gffstnA(gbl-ntlm-auth-srv[serverFQDN])# windows-domain ggh.medarch.org
 assigns a Secure Agent instance to the “ggh.medarch.org” Windows Domain, and
 to the old-style “NHCIFS” domain name.
```

**Related Commands**

[ntlm-auth-server](#)  
[ip address \(gbl-ntlm-auth-srv\)](#)  
[show proxy-user](#)

---

# windows-mgmt-auth

**Purpose** A Windows-management-authorization (WMA) group is a list of Windows clients with permissions to use Windows-management applications (such as MMC) in one or more CIFS namespaces. Use the `windows-mgmt-auth` command to create a WMA group. Use no `windows-mgmt-auth` to remove a WMA group.

**Mode** gbl

**Security Role(s)** crypto-officer

**Syntax** `windows-mgmt-auth name`  
`no windows-mgmt-auth name`

*name* (1-64 characters) is a name you choose for the group.

**Default(s)** None

**Guidelines** This command places you in `gbl-mgmt-auth` mode, where you then add one or more Windows clients and the management permissions for all of them. Use the [user \(gbl-mgmt-auth\)](#) command to add a Windows user to the group. Use the [permit \(gbl-mgmt-auth\)](#) command to add management permissions for these users, such as permission to add CIFS shares, close CIFS files, or view snapshot directories from Windows.

Any CIFS client can list all configured CIFS shares from a CIFS service, whether or not he or she is a member of a WMA group. WMA-group members, given the proper permissions, can also see all volumes behind a CIFS service; this provides a menu for adding new shares to the service.

Use the [show windows-mgmt-auth](#) command to display the configuration for a WMA group.

To apply a WMA group to a namespace, use [windows-mgmt-auth \(gbl-ns\)](#). You can apply multiple groups to the same namespace. Use [browsing](#) to enable Windows management for a CIFS service.

**Samples** `bstnA(gbl)# windows-mgmt-auth fullAccess`  
`bstnA(gbl-mgmt-auth[fullAccess])#`  
starts the configuration of WMA group, "fullAccess."

`bstnA(gbl)# no windows-mgmt-auth testMMC`  
removes a WMA group from the system.

**Related Commands** [user \(gbl-mgmt-auth\)](#)  
[permit \(gbl-mgmt-auth\)](#)  
[show windows-mgmt-auth](#)  
[windows-mgmt-auth \(gbl-ns\)](#)  
[browsing](#)

---

---

## NFS Access Lists

---

---

---

# anonymous-gid

**Purpose** When an NFS client accesses a share as *root* (a UNIX superuser), an NFS-access list typically re-maps the user's identity to that of the *anonymous* user, which has very low access rights. This security feature is called *root squashing*. Use the `anonymous-gid` command to change the Group ID (GID) for the *anonymous* user.

Use the `no` form of the command to revert to the default GID for *anonymous*.

**Mode** gbl-nfs-acl

**Security Level** crypto-officer

**Syntax** `anonymous-gid id`  
`no anonymous-gid`

*id* (1-65535) is a group ID number that the access list uses when it squashes root access.

**Default(s)** 65534

**Guidelines** When permit rules have `root-squash` enabled, they translate the Group ID (GID) of a *root* user to an *anonymous* GID. To set the user ID (UID), use [anonymous-uid](#). Use [show nfs-access-list](#) to see the current GID and UID used for *anonymous*.

**Sample**

```
bstnA(gbl)# nfs-access-list eastcoast
bstnA(gbl-nfs-acl[eastcoast])# anonymous-gid 100
bstnA(gbl-nfs-acl[eastcoast])# ...
sets the anonymous GID to 100.
```

**Related Commands** [nfs-access-list](#)  
[show nfs-access-list](#)  
[anonymous-uid](#)

## anonymous-uid

**Purpose** When an NFS client accesses a share as *root* (a UNIX superuser), an NFS-access list typically re-maps the user's identity to that of the *anonymous* user, which has very low access rights. This security feature is called *root squashing*. Use the `anonymous-uid` command to change the User ID (UID) for the *anonymous* user.

Use the `no` form of the command to revert to the default UID for *anonymous*.

**Mode** `gbl-nfs-acl`

**Security Level** `crypto-officer`

**Syntax** `anonymous-uid id`  
`no anonymous-uid`

*id* (1-65535) is a User ID number that the access list uses when it squashes root access.

**Default(s)** `65534`

**Guidelines** When `permit` rules have `root-squash` enabled, they translate the User ID (UID) of a *root* user to an *anonymous* UID. To set the group ID (GID), use [anonymous-gid](#). Use [show nfs-access-list](#) to see the current GID and UID used for *anonymous*.

**Sample** `bstnA(gbl)# nfs-access-list eastcoast`  
`bstnA(gbl-nfs-acl[eastcoast])# anonymous-uid 100`  
`bstnA(gbl-nfs-acl[eastcoast])# ...`  
sets the *anonymous* UID to 100.

**Related Commands** [anonymous-gid](#)  
[nfs-access-list](#)  
[permit \(gbl-nfs-acl\)](#)

---

# deny

**Purpose** Use this command to deny NFS access for one subnet.  
Use the **no** form of the command to remove a deny rule from the current access list.

**Mode** gbl-nfs-acl

**Security Level** crypto-officer

**Syntax** **deny** *ip-address mask*  
**no deny** *ip-address mask*

*ip-address* (0.0.0.0-255.255.255.255) is the address of the subnet to be denied access.

*mask* (0.0.0.0-255.255.255.255) is the netmask (network part of the ip address).

**Default(s)** None

**Guidelines** You may have a situation where most of a large subnet should be permitted access to NFS, but some portions of the subnet should be denied access. From gbl-nfs-acl mode, use this command to add a deny rule for one subnet. Use the **permit** command to allow access for a subnet. Order is important; if a client matches both rules, only the first one is enforced.

No permit or deny rule is enforced until you exit gbl-nfs-acl mode. This ensures that all permit and deny rules are enforced at once, after you finish setting them up in the desired order. Use the **exit** or **end** command to exit the mode.

**Samples** bstnA(gbl)# **nfs-access-list eastcoast**  
bstnA(gbl-nfs-acl[eastcoast])# **deny 192.168.77.0 255.255.255.0**  
bstnA(gbl-nfs-acl[eastcoast])# **deny 192.168.202.0 255.255.255.0**  
bstnA(gbl-nfs-acl[eastcoast])# **permit 192.168.0.0 255.255.0.0**  
**read-write**  
bstnA(gbl-nfs-acl[eastcoast])# ...

denies access to two Class C subnets, but then permits access to any other IP  
*inside* their Class B supernet, 192.168.0.0/16.

**Related Commands** [nfs-access-list](#)  
[permit \(gbl-nfs-acl\)](#)

## description (gbl-nfs-acl)

**Purpose** Use the optional `description` command to include a descriptive string for an access list.

Use the `no` form of the command to remove the description from the current access list.

**Mode** gbl-nfs-acl

**Security Level** crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-255 characters) is your description for the current access list. Surround the text with quotation marks (“”) if it contains any spaces.

**Default(s)** no description

**Guidelines** The description appears in the detailed output for [show nfs-access-list](#).

**Sample**

```
bstnA(gbl)# nfs-access-list eastcoast
bstnA(gbl-nfs-acl[eastcoast])# description "allowable subnets in MA,
NY, & DC"
bstnA(gbl-nfs-acl[eastcoast])# ...
 adds a description for the current NFS access list.
```

**Related Commands** [nfs-access-list](#)  
[show nfs-access-list](#)

---

## ip address (gbl-nis-dom)

**Purpose** Use the `ip address` command to identify one NIS server for the current NIS domain.  
Use the `no` form of the command to remove one NIS server from the list.

**Mode** gbl-nis-dom

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ip address address`  
`no ip address address`

*address* identifies the NIS server (for example, 192.168.70.128). This address must be on a server/proxy-IP subnet (see [ip proxy-address](#)) or reachable through a gateway on that subnet (via static route: see [ip route](#) to create a static route).

**Default(s)** None

**Guidelines** You can enter this command multiple times to identify up to four servers for the same NIS domain. The switch uses the first server for all of its netgroup lookups, falling back on the rest in case the first server fails or times out. The servers are used in the order that they are defined; if the first server is unreachable, the switch tries the second server, and so on. Use [show nis domain](#) to see the current order of NIS servers.

**Samples** `bstnA(gbl-nis-dom[mydom.org])# ip address 192.168.78.55`  
uses a NIS server for “mydom.org,” at 192.168.78.55.

`bstnA(gbl-nis-dom[mydom.org])# no ip address 10.10.25.1`  
removes one NIS server from the list.

**Related Commands** [nis domain](#)  
[show nis domain](#)  
[ip proxy-address](#)  
[ip route](#)

## nfs-access-list

**Purpose** Use this command to create an access list (optional) for NFS services. An *access list* is a list of IP hosts to which you permit or deny access to the NFS service. You can use an NFS access list (or create additional ones) for any number of NFS services.

Use the **no** form of the command to remove an access list.

If you *do not* include an access list for an exported volume, *all* clients can access the share. See [export \(gbl-nfs\)](#) for more information.

**Mode** gbl

**Security Level** crypto-officer

**Syntax** **nfs-access-list** *List-name*  
**no nfs-access-list** *List-name*

*list-name* (1-64 characters) is a name you choose for the access list.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before creating a new NFS access list; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new objects.)

When you configure an NFS service, you can optionally apply one NFS access list to the service. This command places you in gbl-nfs-acl mode, from which you can configure various permit and deny rules for specific subnets and/or NIS netgroups. For example, you could permit access from the subnet at 192.168.101.0 but deny access from all other subnets. By default, all subnets are denied any access. Use the [permit \(gbl-nfs-acl\)](#) and [deny](#) commands to add permit and deny access rules, respectively. To use NIS netgroups from your back-end servers, use [nis domain](#) to create a NIS domain on the switch, use [nis domain \(gbl-nfs-acl\)](#) to apply it to the access list, and use [permit netgroup](#) to allow access to the hosts in one netgroup.

When you use the **no** form of the command to remove an access list, you must first remove all references to the access list before you can remove the list itself.

**Samples** bstnA(gbl)# **nfs-access-list eastcoast**

This will create a new NFS ACL.

Create NFS ACL ''eastcoast''? [yes/no] **yes**

bstnA(gbl-nfs-acl[eastcoast])# ...

creates a new access list and places you gbl-nfs-acl mode.

bstnA(gbl)# **no nfs-access-list testacl**

removes an NFS access list from the switch configuration.

---

**Related Commands** [anonymous-gid](#)  
[anonymous-uid](#)  
[nis domain \(gbl-nfs-acl\)](#)  
[deny](#)  
[permit \(gbl-nfs-acl\)](#)  
[description \(gbl-nfs-acl\)](#)  
[show nfs-access-list](#)  
[export \(gbl-nfs\)](#)

## nis domain

**Purpose** Use the `nis domain` command to identify a Network Information System (NIS) domain to be used in one or more NFS access lists.

Use `no nis domain` to remove the NIS-domain configuration from the ARX.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `nis domain domain`  
`no nis domain domain`

*domain* (1-256 characters) is the NIS-domain name (for example, “company” or “company.com”).

**Default(s)** None

**Guidelines** This command places you into `gbl-nis-dom` mode, where you use the [ip address \(gbl-nis-dom\)](#) command to identify at least one NIS server for the domain. After you specify one or more NIS servers, the ARX looks up all of the netgroups in the domain, then performs DNS lookups for all hostnames in those netgroups. The results are cached on the switch, to prevent excessive traffic between the switch and the DNS server; the [show nis netgroup](#) command shows the contents of this cache. Use [nis update](#) to refresh this cache by performing all of the necessary lookups.

The switch ignores all users and groups in these netgroups. As a proxy, the ARX does not authenticate specific users and groups; the back-end filers perform user/group authentications, and the switch passes the results back to the client.

You can use [nis domain \(gbl-nfs-acl\)](#) to use this NIS domain in an access list. The [permit netgroup](#) command (see [permit \(gbl-nfs-acl\)](#)) adds a permit rule for one netgroup. Use [show nis domain](#) to view all NIS domains and their configured NIS servers.

**Samples** `bstnA(gbl)# nis domain wwmed.com`  
`bstnA(gbl-nis-dom[wwmed.com])# ...`  
creates a new NIS domain, “wwmed.com.”

`bstnA(gbl)# no nis domain testnis`  
removes a NIS domain.

**Related Commands** [ip address \(gbl-nis-dom\)](#)  
[nis update](#)  
[show nis netgroup](#)  
[show nis domain](#)  
[nis domain \(gbl-nfs-acl\)](#)  
[permit \(gbl-nfs-acl\)](#)

---

## nis domain (gbl-nfs-acl)

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>gbl-nfs-acl nis domain</code> command to set the NIS domain for the current NFS access list.<br>Use <code>no nis domain</code> to remove the NIS domain from the access list.                                                                                                                                                                                                                                                                              |

| <b>Security Role(s)</b> | <code>crypto-officer</code>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Syntax</b>           | <code>nis domain <i>domain</i></code><br><code>no nis domain</code><br><br><i>domain</i> (1-256 characters) is the NIS-domain name (for example, “myorg.org” from <code>lnx3.myorg.org</code> ). This domain must be pre-mapped to a NIS server with the <a href="#">nis domain</a> command, from <code>gbl</code> mode.                                                                                                                                                 |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>       | If you plan to use NIS groups in your NFS access list, you must identify the NIS domain with this command. Use <a href="#">show nis domain</a> for a list of configured NIS domains, or use <a href="#">nis domain</a> to create a new one. To view the netgroups in a domain, use <a href="#">show nis netgroup</a> .<br>The <code>permit netgroup</code> command ( <a href="#">permit (gbl-nfs-acl)</a> ) permits all hosts in a netgroup to pass the NFS access list. |
| <b>Samples</b>          | <pre>bstnA(gbl-nfs-acl[westcoast])# nis domain sfmed.com</pre> sets the NIS domain to “sfmed.com” for the “westcoast” access list.<br><br><pre>bstnA(gbl-nfs-acl[midwest])# no nis-domain</pre> removes the NIS domain setting from the “midwest” access list.                                                                                                                                                                                                           |
| <b>Related Commands</b> | <a href="#">permit (gbl-nfs-acl)</a><br><a href="#">show nis domain</a><br><a href="#">nis domain</a>                                                                                                                                                                                                                                                                                                                                                                    |

## nis update

**Purpose** The ARX caches a database of NIS netgroups and all of their DNS-resolved IP addresses. Use the `nis update` command to refresh this cache by querying the NIS server(s) and the local DNS server(s).

**Mode** `priv-exec`

**Security Role(s)** `network-technician, network-engineer, storage-engineer or crypto-officer`

**Syntax** `nis update [domain]`

*domain* (1-256 characters) focuses the update on a single NIS domain. Use `show nis domain` to view all NIS domains. If this is omitted, the switch refreshes its cache for all configured NIS domains.

**Default(s)** `None`

**Guidelines** This command creates one report per updated domain. Each report is named “`nis-update.domain-name.rpt.`” Use `show reports` to list all reports, including NIS-update reports. To follow the progress of the NIS-update operation, you can use `tail reports report-name` follow. Use `show reports file-name` to read the report. You can search through the report with `grep`. To copy or delete it, use the `copy` or `delete` commands. If you want to truncate the report before it finishes, use the `truncate-report` command.

To schedule this command to run on a regular basis, use the `at` command.

The `show nis netgroup` command shows the netgroups in a NIS domain, or the hosts in a particular netgroup. This is the contents of the current NIS-netgroup cache. The `show nis domain` command shows when the most-recent NIS update occurred.

In a redundant pair, the NIS update works independently on each peer. The output of `show nis netgroup` and the NIS reports therefore only apply to the current peer. The benefit of these redundant updates is that failovers do not incur any extra down time for NIS.

**Samples** `bstnA# nis update`  
updates all NIS domains on the switch.

`bstnA# nis update wwmed.com`  
updates a single NIS domain, “`wwmed.com.`”

**Related Commands** `at`  
`show nis domain`  
`show nis netgroup`  
`nis domain`

## permit (gbl-nfs-acl)

**Purpose** Use this command to permit NFS access for one trusted subnet or NIS netgroup.  
Use the `no` form of the command to remove a permit rule for a subnet or netgroup.

**Mode** gbl-nfs-acl

**Security Level** crypto-officer

**Syntax: permit (for a subnet)** `permit ip-address mask [read-only] [ root {squash | allow} ]`  
`no permit ip-address mask [read-only] [ root {squash | allow} ]`

*ip-address* (0.0.0.0–255.255.255.255) is the address of the subnet to be allowed access.

*mask* (0.0.0.0–255.255.255.255) is the netmask (network part of the ip address).

**read-only** (optional) limits users to read-only access.

`root` (optional) applies this rule to root-user access and requires one of the following keywords:

**squash** disables root access and remaps it to the configured UID and GID settings (provides more security).

**allow** enables root-user access.

**Syntax: permit netgroup** `permit netgroup group-name [read-only] [ root {squash | allow} ]`  
`no permit netgroup group-name`

*group-name* (1-1024) is the address of the NIS netgroup to be allowed access.

**read-only** (optional) limits users to read-only access.

`root` (optional) applies this rule to root-user access and requires one of the following keywords:

**squash** disables root access and remaps it to the configured UID and GID settings (provides more security).

**allow** enables root-user access.

**Default(s)** read-write;  
root squash.

**Guidelines** By default, a new NFS access list denies access to all subnets and NIS netgroups. This command enables you to selectively allow access for a trusted subnet or netgroup.

An access list can only use netgroups from a single NIS domain; use [nis domain \(gbl-nfs-acl\)](#) to choose one for the current access list.

An NFS-access list can support a maximum of 2048 rules. Each host in a NIS netgroup results in a separate rule, so use [show nfs-access-list ... resolve-netgroups](#) to verify that the netgroups are not too large for the access list.

A new permit rule squashes root access by default. That is, if a client logs in as the *root* user and accesses the NFS share, the ARX translates the client's user ID to an *anonymous* ID with limited access privileges. In *gbl-nfs-acl* mode, you can change the anonymous User/Group IDs through the [anonymous-gid](#) and [anonymous-uid](#) commands.

The *no* form of the command always removes the rule, whether or not you specify any options (such as *read-write*, *root allow*, and so on). This facilitates copying and pasting a rule from the [show nfs-access-list](#) output to the CLI and placing a *no* in front of it.

**Guidelines: Rule Order** The order that you enter rules determines the order in which they are compared to client IPs. If a client's IP address matches more than one rule in the access list, the ARX uses the first matching rule and ignores the rest.

For example, consider the two permit rules below. Clients in 192.168.10.x match the first rule, while clients outside that subnet in the same Class B network (192.168.x.x) match the second rule. This allows read-only access to clients in the Class B network but full read-write access to clients in the smaller Class-C subnet:

```
permit 192.168.10.0 255.255.255.0 read-write
permit 192.168.0.0 255.255.0.0 read-only
```

If the rules were reversed, clients in the Class C subnet would match the read-only rule before reaching the read-write rule that was intended for them.

No permit or deny rule is enforced until you exit *gbl-nfs-acl* mode. This ensures that all permit and deny rules are enforced at once, after you finish setting them up in the desired order. Use the *exit* or *end* command to exit the mode.

**Samples**

```
bstnA(gbl)# nfs-access-list eastcoast
bstnA(gbl-nfs-acl[eastcoast])# permit 172.16.100.0 255.255.255.0
read-write
bstnA(gbl-nfs-acl[eastcoast])# ...
 permits read-write access to clients at 172.16.100.0.
```

```
bstnA(gbl)# nfs-access-list eastcoast
bstnA(gbl-nfs-acl[eastcoast])# permit 172.16.204.0 255.255.255.0
read-only root allow
bstnA(gbl-nfs-acl[eastcoast])# ...
 allows root access from clients at 172.16.204.0. To control security, access is
 read-only for this rule.
```

```
bstnA(gbl-nfs-acl[eastcoast])# permit netgroup nurses
 permits access to all hosts in the "nurses" netgroup.
```

[show nfs-access-list](#)

---

## show nfs-access-list

**Purpose** Use this command to display a summary of all configured NFS access lists or specify an individual list to view its details.

**Mode** (any)

**Security Level** operator

**Syntax** `show nfs-access-list [list-name [resolve-netgroups]]`

*list-name* (optional; 1-64 characters) is the access list you want to view.

**resolve-netgroups** (optional) expands the NIS netgroups. This shows every resolved host in every NIS netgroup, in order. Without this option, netgroups are summarized on a single line and counted as a single rule.

**Default(s)** None

**Guidelines** The show nfs-access-list command displays the following information:

**Access List Name:** The names of all configured access lists.

**Anon UID:** The anonymous User ID number assigned to *root* when root squashing is enabled (the default). You can change this with [anonymous-uid](#).

**Anon GID:** The anonymous Group ID number assigned to *root* when root squashing is enabled (the default). Use [anonymous-gid](#) to edit this.

**Num Rules:** The number of permit and/or deny rules applied to this access list. This counts each NIS netgroup as a single rule; use the **resolve-netgroups** command to find the total count, including every host in every netgroup.

**Num References:** The number of times this access list is used by an NFS service(s).

**Guidelines: Detailed Output**

If you enter a list name, the output also shows the [description \(gbl-nfs-acl\)](#) for the access list, if any, and the list's exact rules. The order is important; if a client matches two rules in the list, the switch follows the first rule and ignores the second.

Two additional fields appear at the bottom if you use the [resolve-netgroups](#) flag:

**Number of entries in access list:** The total number of rules, including each host in the expanded netgroups. An error appears above this field if the number of rules exceeds the maximum, 2048. Each host in a netgroup requires a rule, so large netgroups can cause an access list to exceed its maximum. Only the first 2048 rules are used.

**Status line:** A line summarizes the results of resolving all NIS netgroups and each hostname in the netgroup:

- “All Netgroup(s) were successfully resolved.” This indicates success.
- “Netgroup(s) were not completely resolved.” This may indicate that one or more hosts in the NIS netgroups cannot be resolved at the local DNS server. Use [show ip domain](#) to find the DNS servers that the switch is using.
- “Domain was not found.” The NIS domain for this access list, set with [nis domain \(gbl-nfs-acl\)](#), is not supported at the NIS server. Use [show nis domain](#) to find the NIS server(s) used by the ARX.
- “One or more Netgroup(s) were not found.” A NIS netgroup contained another NIS netgroup as one of its members; the NIS server did not define one or more of these member netgroups.
- “The switch has not resolved all netgroups for this domain.” Either the first update is not yet finished (for example, right after finishing the NIS configuration or rebooting the switch), or every NIS update has failed since the most-recent reboot. Use [nis update](#) to invoke another NIS update.

**Samples**

**bstnA# show nfs-access-list**  
displays a list of all configured access lists. For example, see [Figure 19.2](#).

**bstnA# show nfs-access-list eastcoast**  
displays detailed information for this access list, including the permit and deny rules for the associated subnet(s) and/or netgroups. See [Figure 19.3 on page 19-19](#) for sample output.

**bstnA# show nfs-access-list eastcoast resolve-netgroups**  
expands all NIS netgroups into their component rules, one rule per host in the netgroup. See [Figure 19.4 on page 19-19](#) for sample output.

## show nis domain

- Purpose** Use this command to display a summary of all configured NIS domains, or to show details for one NIS-domain configuration.
- Mode** (any)
- Security Level** operator
- Syntax** `show nis domain [domain-name]`
- domain-name* (optional; 1-256 characters) is the NIS domain you want to view. If you omit this, the output displays a summary of all NIS domains configured on the switch.
- Default(s)** None
- Guidelines** The summary form of the `show nis domain` command displays the following information:
- NIS Domain** is the name of the NIS domain. Use the [nis domain](#) command to configure a new NIS domain, or change an existing one.
- Last Update** is the date and time that the ARX last updated its internal NIS database. This occurs when each NIS domain is first configured, and whenever someone issues the [nis update](#) command.
- Status** summarizes the results of the most-recent NIS update. This is “Success,” “Updating,” or “Failed.”
- Servers** are the NIS servers for this NIS domain. You can use the [ip address \(gbl-nis-dom\)](#) command to identify more servers that support this domain. This shows the order in which the servers are used; if the first server fails, the switch tries the second, and so on.
- The detailed output adds several more fields:
- Last Successful Update** is the date and time for the last NIS update that ended with a “Success” status.
- Netgroups** is the number of netgroups defined for this NIS domain.
- Netgroup Resolution Errors** is the number of netgroup entries that the switch failed to parse. These are typically malformed lines in the NIS server’s configuration file for netgroups.
- Hosts** is the number of hosts found in all the netgroups.
- Hosts Resolved** is the number of hosts that were successfully resolved to IP addresses. These are DNS resolutions, made by an external DNS server; use [show ip domain](#) to see the DNS server(s) used by this switch. If this number is lower than the number for **Hosts**, above, some hosts were not resolved.
- Samples**
- bstnA# `show nis domain`  
displays a list of all configured NIS domains. See [Figure 19.5](#) for sample output.
- bstnA# `show nis domain wwmed.com`  
displays detailed information for the “wwmed.com” NIS domain. [Figure 19.6](#) shows sample output.

## show nis netgroup

**Purpose** Use this command to list the netgroups in a given NIS domain, or to show all of the hosts in a given netgroup.

**Mode** (any)

**Security Level** operator

**Syntax** `show nis netgroup domain [netgroup]`

*domain* (1-256 characters) is the NIS domain you want to view.

*netgroup* (optional; 1-1024 characters) specifies a single netgroup. If you enter this, the command shows all hosts in the netgroup.

**Default(s)** None

**Guidelines** The summary form of the `show nis netgroup` command displays an alphabetical list of all netgroups defined for the domain. The ARX finds these at the back-end NIS servers; use [show nis domain](#) for a list of NIS servers.

The detailed form of the command shows a table with one row for each host found in the netgroup. The **Hostname** is the name found in the netgroup, and the **IP Address** is resolved at the local DNS server. Use [show ip domain](#) for a list of local DNS servers.

The switch ignores all users and groups in the netgroup. As a proxy, the ARX does not authenticate specific users and groups; the back-end filers perform user/group authentications, and the switch passes the results back to the client.

**Samples** `bstnA# show nis netgroup wwmed.com`  
displays a list of all netgroups in the “wwmed.com” domain. See [Figure 19.7](#) for sample output.

`bstnA# show nis netgroup wwmed.com medtechs`  
shows every host in the “medtechs” netgroup. [Figure 19.8](#) shows sample output.

| <b>Purpose</b>          | <p>Some Tier-2 CIFS filers can only support a limited number of simultaneous CIFS connections. You can use the <code>cifs connection-limit</code> command to set a maximum number of CIFS connections from the ARX to the current filer.</p> <p>For filers and servers that can support a large number of CIFS connections, you can use the <code>no cifs connection-limit</code> command. This removes any restriction on CIFS connections between the ARX and the filer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Mode</b>             | gbl-filer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Guidelines</b>       | <p>This command is only necessary for filers that can support a limited number of CIFS connections.</p> <p>If you set a limit that is lower than the current number of CIFS connections, the CLI prompts you with a choice: you can drop all connections immediately or block new connections until enough of the current connections drop off. If you choose to wait, you always have the option to later use the <code>drop filer-connections</code> command, which forces the connections to terminate immediately. To show the current connections to the filer, use <code>show filer connections</code>. The <code>show statistics filer connections</code> command shows connection statistics over time, and the <code>clear statistics filer connections</code> command clears the statistics.</p> <p>All external filers with the same IP address must have the same number of connection limits. That is, if your configuration includes more than one “external-filer” object for the same back-end filer, this command sets the same connection limit for both objects. Each NSM processor always has at least 2 CIFS connections per filer.</p> |
| <b>Sample</b>           | <pre>bstnA(gbl-filer[smb1])# cifs connection-limit 500</pre> <p>limits the ARX to 500 CIFS connections between itself and the “smb1” filer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## cifs-port

**Purpose** For filers that do not use a well-known port for CIFS, use the `cifs-port` command to set the CIFS port.

Use the `no` form of this command to use well-known CIFS ports.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `cifs-port port`  
`no cifs-port`

*port* is the TCP port number (1-65535).

**Default(s)** TCP 445, falling back to 139. See the *Guidelines* below.

**Guidelines** By default, the ARX sends its CIFS messages to port 445 or 139 at the external filer. Port 445 supports raw CIFS communication over TCP, port 139 supports CIFS through NetBIOS; the ARX tries port 445 first, then falls back to 139 if that fails. For filers that do not listen at either of these well-known ports, use the `cifs-port` command to set the port.

Whenever the ARX falls back to port 139 to make a NetBIOS connection, it uses a “Source Computer” name of “ACOPIA\_SWITCH.” Every proxy-IP address identifies itself by this same name. You can see this name through MMC, by examining “Active Sessions” on the back-end filer.

This command is not needed for external filers that support NFS exports.

**Sample** `bstnA(gbl-filer[fs2])# cifs-port 1111`  
sets the CIFS port to 1111.

**Related Commands** [external-filer](#)

---

## description (gbl-filer)

**Purpose** Use the optional **description** command to set a descriptive string for the current external filer. This appears in the show command.

Use the **no** form of the command to delete the description.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **description *text***  
**no description**

*text* (1-255 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** no description

**Guidelines** The description appears in the output for [show external-filer](#).

**Sample** bstnA(gbl-filer[das1])# **description "shares with financial data (LINUX filer, rack 14)"**

specifies a description for the current external filer.

**Related Commands** [external-filer](#)  
[show external-filer](#)

## external-filer

**Purpose** Use the `external-filer` command to begin external-filer configuration. This is a logical representation of an external file server or NAS filer connected to the ARX.

Use the `no` form of this command to remove the external-filer configuration.

**Mode** `gbl`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `external-filer name`  
`no external-filer name`

*name* is a name that you choose for the external filer. Use up to 64 characters. You cannot use “all;” this is a reserved keyword.

**Default(s)** None.

**Guidelines** When you create a new external filer, this command prompts for confirmation. Enter `yes` to continue.

This command puts you into `gbl-filer` mode. From that mode, you must use `ip address` to identify the external filer. If the filer is a Windows cluster, you must also use `spn` to provide the Service-Principal Name (SPN) for the cluster.

You can also use the `description (gbl-filer)` command to describe the filer.

The ARX uses the following NFS settings for the external filer:

- NFS port from a call to the filer’s portmapper service,
- NFS-mount port from a call to the filer’s portmapper service,
- Unix User ID 0 (*root*) to read the filer’s directory trees, and
- a null NIS domain.

An external filer’s default CIFS port is 445, or 139 for filers that do not support CIFS over raw TCP; use `cifs-port` to change this, if necessary.

Use `show external-filer` to show the filer configuration. The `show statistics namespace ... fastpath` command shows read/write statistics for each of the filer’s shares. For statistics on NFS and/or CIFS traffic between the switch and this filer, use `show statistics filer`. You can use `show filer connections` to see all current connections from the switch to the filer.

**Guidelines:** If the filer supports snapshots (point-in-time copies), you can use several commands to prepare it for use in an ARX snapshot. The `filer-type` command identifies the filer’s vendor. The `proxy-user (gbl-filer)` command associates a proxy user with this filer, so that the ARX can use its credentials to access the filer’s CLI or API. (An ARX volume coordinates its snapshots by logging into its filers and issuing snapshot commands.) You can also use the `ip address ... management` command to specify a management IP for accessing the CLI (by default, the ARX volume uses the primary-IP address). The `manage snapshots` command declares that the filer can support snapshots or checkpoints.

---

**Guidelines: Changing the Filer's IP Address**

You can change the primary by re-running the [ip address](#) command with a new address, before the filer is used in any [volume](#). After any of the filer's shares are used in any volume, you can only change the address with [ip address ... change-to](#), followed by a failover or reboot ([reload](#)).

**Samples**

```
bstnA(gbl)# external-filer das1
This will create a new filer.
```

```
Create filer 'das1'? [yes/no] yes
bstnA(gbl-filer[das1])#
 creates an external filer named "das1."
```

```
bstnA(gbl)# no external-filer das1
 removes the configuration for the external filer named "das1."
```

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | You can use the <a href="#">ip address ... change-to</a> command to prepare for changing one or more IP addresses for your <b>external-filers</b> , then use this command to reboot the ARX and activate all the address changes. If the ARX has a redundant peer, this command reboots both peers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Security Role(s)</b> | network-technician, network-engineer, storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Syntax</b>           | <b>ext-filer-ip-addr activate</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>       | <p>This command causes the current ARX (and its redundant peer, if there is one) to reboot. This causes a service outage, so you should run the command during non-busy hours. The CLI prompts for confirmation before rebooting; enter <b>yes</b> to proceed.</p> <p>After the reboot(s) finish, all IP-address changes made by the <a href="#">ip address ... change-to</a> command go into effect. The <a href="#">ip address ... change-to</a> command has no effect on client/server traffic until you invoke this command.</p> <p>If there are no IP-address changes pending, the command prompts you that there is nothing to do. No reboot occurs in this case. As mentioned above, you can use the <a href="#">ip address ... change-to</a> command to prepare for changing a filer's IP address.</p> <p>The <a href="#">ip address ... change-to</a> command is only necessary after one of the filer's shares or exports is used in an ARX <b>volume</b>. If none of the filer's shares are in active use, you can re-run the <a href="#">ip address</a> command to change the address, and the <b>ext-filer-ip-addr activate</b> command is unnecessary.</p> |
| <b>Samples</b>          | <pre>bstnA# ext-filer-ip-addr activate</pre> <p>Activates all new external filer primary IP addresses and reboots the chassis.</p> <pre>Are you sure? [yes/no] yes</pre> <p>activates all IP-address changes made by the <a href="#">ip address ... change-to</a> command and reboots the ARX. This would also reboot the redundant peer if one was configured.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Related Commands</b> | <a href="#">external-filer</a><br><a href="#">ip address ... change-to</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

---

## filer-type

**Purpose** An ARX volume can coordinate *snapshots* (point-in-time copies) of all of its back-end shares. To support these coordinated snapshots, the ARX volume logs into each filer's CLI and runs snapshot or checkpoint commands. Use the **filer-type** command for a filer that supports snapshots, to identify the filer vendor. An ARX volume can use this information to determine the proper CLI-command set to invoke snapshots or checkpoints.

Use the **no** form of this command to designate no filer type. This makes it impossible for an ARX volume to use the filer for coordinated snapshots.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **filer-type network-appliance** [**management-protocol** {**ssh** | **rsh**}]  
**filer-type emc** [**nas-db-path** *path*]  
**filer-type data-domain**  
**filer-type bluearc**  
**filer-type windows** [**cluster**] [**port** *winrm-port*]  
**no filer-type**

**network-appliance** declares that NetApp is the vendor for this filer.

**management-protocol** {**ssh** | **rsh**} (optional) chooses the shell protocol for accessing the filer's CLI. The default is SSH. For NetApp filers that do not allow SSH access, you can use **management-protocol rsh**.

**emc** indicates that this is an EMC Celerra server.

**nas-db-path** *path* (optional, 1-64 characters) defines a unique NAS-database path for an EMC Celerra server. Specifically, this is the value of the `NAS_DB` environment variable on the server. The default for this path is `"/nas;"` contact EMC Support for the proper setting on your EMC server.

**data-domain** means that the filer is an EMC Data Domain system. The CLI uses SSH to access the Data Domain CLI.

**bluearc** indicates that the filer is Hitachi HNAS, powered by BlueArc. The CLI uses SSH to access the BlueArc CLI.

**windows** means that the filer is a Windows server that supports snapshots and management through WinRM (see *Guidelines*, below).

**cluster** (optional) asserts that this is in a Windows server 2008 (or later) cluster. If the Windows cluster has NetBIOS disabled, there is no way for the ARX software to automatically determine that it is a cluster, and this information is necessary to support snapshots. You can use this option to overcome this issue and directly inform the ARX.

**port** *winrm-port* (optional, 1-65535) specifies the port where the server's WinRM listener is waiting for instructions.

**Default(s)** **no filer-type**  
**nas-db-path path** - the *path* default is “/nas”  
**cluster** - by default, this flag is down and the ARX attempts to automatically discover if the filer is in a cluster  
**port winrm-port** - the default for *winrm-port* is 80, the HTTP port.

**Guidelines** This command identifies the vendor of the current filer. You must use this command to prepare the filer for coordinated-snapshot support with a [snapshot rule](#). Additionally, you must create a [proxy-user](#) with credentials for logging into the filer’s management interface, and you must use the [proxy-user \(gbl-filer\)](#) command to associate that proxy user with this filer. You can also use the [ip address ... management](#) command to specify a management IP for accessing the CLI (by default, the ARX volume uses the primary-IP address). The [manage snapshots](#) command declares that the filer is eligible for ARX snapshots.

**Guidelines: NetApp Settings** Each NetApp volume to be used for ARX snapshots must have the `nosnapdir` option turned off. From the NetApp CLI, you can use the `vol options` command to turn this option off. For example: `vol options vol2 nosnapdir off`.

If you use `management-protocol ssh` (the default), please verify that the idle timeout value, `ssh.idle.timeout`, is set properly. The ARX cannot create snapshots on the NetApp if this option is set to 0 (zero). From the NetApp CLI, use `options ssh` to check the current timeout setting, and use `options ssh.idle.timeout 600` to set the idle timeout to 600 seconds (the default for most releases).

**Guidelines: Windows and WinRM** A Windows filer must have Windows Remote Management (WinRM) installed and configured for the ARX to manage its snapshots. The minimum configuration is a WinRM listener that allows HTTP negotiations (encrypted or unencrypted), and allows up to 5 minutes before timing out a snapshot operation. Use the `port` option if the listener is waiting at any IP port other than 80. The ARX volume communicates with the WinRM listener to create, list, and remove snapshots from the Windows Server. The ARX uses Kerberos authentication over HTTP; use [active-directory update seed-domain](#) to prepare for Kerberos authentication.

You can use the following command at the Windows filer’s DOS prompt to create a 5-minute timeout for snapshots: `winrm set winrm/config @{MaxTimeoutms="300000"}`.

- 
- Samples** `bstnA(gbl-filer[nas10])# filer-type network-appliance`  
designates the “nas10” filer as a NetApp filer that supports ARX snapshots.
- `bstnA(gbl-filer[nas2])# filer-type network-appliance management-protocol rsh`  
establishes RSH as the shell protocol for accessing the “nas2” filer, another NetApp device.
- `bstnA(gbl-filer[fs2])# filer-type windows`  
designates the “fs2” filer as a Windows server that supports ARX snapshots. This sends its WinRM instructions through the default port, 80. If “fs2” is part of a Windows server 2008 (or later) cluster, it presumes that NetBIOS is enabled on that cluster, and the ARX can therefore automatically discover its cluster membership.
- `bstnA(gbl-filer[nasE4])# filer-type emc nas-db-path /nas/rdp/500`  
declares that “nasE4” is an EMC Celerra server with a non-default NAS\_DB value of “/nas/rdp/500.”
- `bstnA(gbl-filer[das1])# no filer-type`  
indicates that the “das1” filer does not support ARX snapshots or CLI/API access.

## ignore-name

**Purpose** Some directories are only related to a filer’s local operation, such as local snapshot and checkpoint directories, and should not be presented to the client. Use the `ignore-name` command to identify each virtual directory to be ignored by the ARX. The ARX also ignores all files with the same name.  
Use the `no` form of this command to remove a directory from the “ignore list.”

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ignore-name directory`  
`no ignore-name directory`

*directory* (1-256 characters) identifies the directory to be ignored (for example, “.snapshot”). Do not use any slashes (/) in the directory name; “mydir” is valid, but “mydir/subdir” is not. You can use a \* at the end of the directory name as a wildcard, as long as the directory name starts with a “.” and contains at least three characters. These wildcards only apply to the root of the share: “.ignore\*” ignores /.ignore2, but does not ignore /docs/.ignore7.

**Default(s)** .snapshot, ~snapshot, .etc, .ckpt\*, \$RECYCLE.BIN, System Volume Information, SIS Common Store

**Guidelines** The `filer` command includes directories into a namespace volume. This command omits any subdirectories that should not be included. You can ignore up to eight directories per external filer.

As mentioned above, this command also makes the ARX ignore files of the same name.

Ignore only virtual directories like “~snapshot” and “lost+found.” If you ignore a real directory (or file) that exists below the share’s root, clients cannot delete the ignored directory/file’s parent. For example, if you ignore “/ignoreMe” directories and a “/var/export” share contains “/var/export/myDir/ignoreMe,” clients cannot delete “/var/export/myDir.”

The directory is ignored for all shares on the filer; for example, if a “.ckpt1” directory appears in each of three shares, it is ignored in all three of them.

The CLI prompts for confirmation if you use a wildcard. Enter `yes` to continue.

Several filer vendors have sets of directories that they commonly use for backups, snapshots, and storage maintenance. All except “lost+found” are ignored by default:

- EMC: .etc, lost+found, .ckpt\*
- EMC Data Domain: .snapshot
- Network Appliance: .snapshot, ~snapshot
- Windows: “System Volume Information”, “SIS Common Store”
- Hitachi HNAS, powered by BlueArc: .snapshot, ~snapshot

The `show external-filer` command shows all ignored directories.

**Samples** `bstnA(gbl-filer[nas10])# ignore-name ~snapshot`  
ignores all “~snapshot” directories on the “nas10” filer.

`bstnA(gbl-filer[nasE1])# ignore-name .ckpt*`  
Wildcard matches are only made in the root directory of a share.  
Is this the intended behavior? [yes/no] **yes**  
ignores all directories starting with “.ckpt” on the “nasE1” filer (.ckpt1, .ckpt2, ...  
.ckpt33, and so on).

`bstnA(gbl-filer[das1])# no ignore-name .bin`  
stops ignoring all “.bin” directories.

[show external-filer](#)

## ip address

**Purpose** Use the `ip address` command to identify the filer or file server associated with the current `external-filer` configuration object.

Use the `no` form of the command to remove an IP address from the current `external-filer` configuration.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ip address address [secondary | management]`  
`no ip address address [secondary | management]`

*address* identifies the external filer (for example, 192.168.70.65). This address must be on a server/proxy-IP subnet (see [ip proxy-address](#)) or reachable through a gateway on that subnet (via static route: see [ip route](#) to create a static route).

**secondary** (optional) flags a physical-IP addresses in a multi-homed filer. Some filers are configured redundantly, accepting all packets at a shared virtual-IP address and responding to some UDP packets from their physical-IP addresses. For these filers, enter the virtual-IP address without any flag, then add up to four physical addresses with the **secondary** flag. Note that CIFS is a TCP-only protocol, so this option is unnecessary if you only use the filer for CIFS.

**management** (optional) is for an out-of-band (OOB) or external management address. The ARX uses this address to access the filer's CLI. A volume with a [snapshot rule](#) accesses the CLI to issue snapshot or checkpoint commands at the filer. If you do not specify any IP address with this flag, it uses the primary-IP address.

**Default(s)** None

**Guidelines** This command is required for configuring a NAS device or file server as an external filer. To verify that the address is valid in the current configuration, use the [show exports](#) command before you use this one.

You can repeat this command up to four times with the **secondary** flag, to identify secondary addresses for the filer. The **management** flag indicates an interface for accessing the filer's CLI; this is unnecessary if the CLI is accessible through the primary interface.

To change the primary IP address of a filer whose storage is in use, you can use the [ip address ... change-to](#) command followed by the [reload](#) command. If the filer does not have any exports or shares used by any [volume](#), you can change the IP address by re-running this command with the new address.

**Samples** `bstnA(gbl-filer[das1])# ip address 192.168.25.19`  
designates 192.168.25.19 as the IP address for the “*das1*” filer.

`bstnA(gbl-filer[nas3])# ip address 192.168.25.133`  
`bstnA(gbl-filer[nas3])# ip address 192.168.25.134 secondary`  
`bstnA(gbl-filer[nas3])# ip address 192.168.25.135 secondary`  
specifies that 192.168.25.133 is the primary address for “*nas3*,” then identifies two secondary addresses.

`bstnA(gbl-filer[nasE1])# ip address 192.168.25.51`  
`bstnA(gbl-filer[nasE1])# ip address 192.168.25.52 management`  
provides a primary address and a separate management address for the “*nasE1*” filer.

**Related Commands** [external-filer](#)  
[ip proxy-address](#)  
[ip route](#)  
[show exports](#)  
[show external-filer](#)

## ip address ... change-to

**Purpose** Use the `ip address ... change-to` command to prepare for changing the current external-filer's IP address. The new IP address becomes the primary IP address for the filer the next time someone uses the `ext-filer-ip-addr activate` command.

Use the `no` form of the command to remove the new IP address from the current external-filer configuration. Use this if you want the external filer's IP address to remain the same in case someone invokes `ext-filer-ip-addr activate`.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ip address address change-to new-address`  
`no ip address address change-to new-address`

*address* identifies an existing external filer. You can use `show external-filer` for a full list of external filers and their IP addresses.

*new-address* is the address to assign to this filer the next time someone invokes `ext-filer-ip-addr activate`. You cannot use an existing secondary address (set with the `ip address` command) or any other IP address that is already in use on the ARX.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before reserving a new IP address for the `external-filer`; enter `yes` to proceed.

This command has no effect on client/server traffic until someone uses `ext-filer-ip-addr activate` to activate the change. After you run this command, you can change the IP address of the filer itself, and then use the `ext-filer-ip-addr activate` command to reboot the ARX or ARX pair. You only need to activate once for multiple IP-address changes.

This command is only necessary after one of the filer's shares or exports is used in an ARX `volume`. If none of the filer's shares are in active use, you can re-run the `ip address` command to immediately change the address.

**Guidelines: IP Address Settings that are Unaffected by this Command**

The `ip address ... change-to` command has no effect on the following IP-address settings:

- The `quorum-disk` share, used for `redundancy`. If the filer is the host for a quorum-disk share, you must re-run the `quorum-disk` command with the new IP address to re-connect to the quorum disk. Run this command on both ARX peers in the redundant pair.
- The management-IP address used for snapshots and other filer-CLI access. If the filer has shares with snapshots, and the management IP changes, you must re-run the `ip address ... management` command to continue to support an ARX `snapshot rule` at this filer.

The `ext-filer-ip-addr activate` command is not necessary for these commands to take effect.

---

**Samples** bstnA(gbl-filer[nas3])# **ip address 192.168.25.133 change-to 192.168.25.198**  
This operation will add the IP address for the external filer as the new IP address.  
This change will not take effect until after 'ext-filer-ip-addr activate' is run.  
Change the external filer's IP address ? [yes/no] **yes**  
assigns a new IP address to the external-filer named "nas3." The new address, 192.168.25.198, takes affect the next time someone runs [ext-filer-ip-addr activate](#).

bstnA(gbl-filer[nas3])# **no ip address 192.168.25.133 change-to 192.168.25.198**  
nullifies the above command. The IP address for "nas3" will remain the same if anyone runs [ext-filer-ip-addr activate](#).

**Related Commands** [external-filer](#)  
[ip address](#)  
[show external-filer](#)  
[ext-filer-ip-addr activate](#)

## manage snapshots

**Purpose** An ARX volume can coordinate *snapshots* (point-in-time copies) of all of its back-end shares. A limited number of filers and filer-OS releases support snapshots. Use the `manage snapshots` command to indicate that the current filer supports coordinated snapshots.

Use the `no` form of this command to indicate that the current filer does not support snapshots.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `manage snapshots`  
`no manage snapshots`

**Default(s)** `no manage snapshots`

**Guidelines** This command declares that the filer can support snapshots. This is the final command to prepare the filer for coordinated-snapshot support with a [snapshot rule](#). Before you enter this command, use the [filer-type](#) command to enter some vendor-specific information about the filer. Additionally, you must create a [proxy-user](#) with the credentials for accessing into the filer's CLI or API, and you must use the [proxy-user \(gbl-filer\)](#) command to associate that proxy user with this filer. For some filers, you can use the [ip address ... management](#) command to specify a management IP for accessing the CLI (by default, the ARX volume uses the primary-IP address).

You can use the `no manage snapshots` command to suspend snapshot support on an entire filer. While this is disabled, no snapshot rule can take a snapshot on the filer. In a volume where other back-end filers support snapshots, this creates a *sparse snapshot* from which some of the volume's shares are *excluded*. You may want to create one or more [place-rules](#) to ensure that the snapshot-capable filers contain all the files that require backups. Run the affirmative form of the command, `manage snapshots`, to reinstate ARX snapshots on the filer.

**Samples** `bstnA(gbl-filer[nas10])# manage snapshots`  
allows the ARX to take snapshots on the "nas10" filer.

`bstnA(gbl-filer[das1])# no manage snapshots`  
indicates that the "das1" filer does not support ARX snapshots.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | For filers that support NFSv3 over TCP, you may be able to improve import performance by increasing the number of TCP connections. Before you add any of the filer's shares to a namespace volume, you can use the <code>nfs tcp connections</code> command to increase the number of connections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Mode</b>             | gbl-filer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Syntax</b>           | <code>nfs tcp connections {1   2   4   8   16   32}</code><br><br>1   2   4   8   16   32 is the number of connections to use. The ARX-1500, ARX-2500, and ARX-VE each support a maximum of 8 connections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Default(s)</b>       | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Guidelines</b>       | <p>By default, the ARX creates 1 TCP connection to an NFSv3/TCP filer. It establishes this connection when one of its shares is incorporated into a namespace volume (using the <code>filer</code> command). For some NFS filers, import speed may improve if you use multiple TCP connections. Consult your vendor documentation and F5 Support before changing this default.</p> <p>The number of NFSv3/TCP connections to the filer persists as long as any of its NFS shares are used in a namespace. The namespace uses these connections for all of its communication with the filer. In case of a prior connection, this command has no effect until the next ARX reboot. To change the number of connections, use this command and then <code>reload</code> the ARX.</p> <p>The output of the <code>show filer connections</code> command shows all of the current connections to a given filer.</p> <p>To change the maximum CIFS connections to the filer, use <code>cifs connection-limit</code>.</p> |
| <b>Sample</b>           | <pre>bstnA(gbl-filer[nas1])# nfs tcp connections 16</pre> uses 16 TCP connections to the "nas1" filer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## probe authentication

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                                    | The ARX may use Kerberos, NTLM, or NTLMv2 to authenticate with the CIFS filers behind it. Use the <b>probe authentication</b> command to test any of these authentication methods against any desired CIFS filer. This is useful for testing authentication methods in your network, qualifying an external filer or DC for inclusion in the ARX configuration, or for troubleshooting filers and DCs that are already used in the configuration. |
| <b>Mode</b>                                       | priv-exec                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Security Role(s)</b>                           | crypto-officer or storage-engineer                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Syntax:</b><br><b>Not-Yet Configured Filer</b> | <b>probe authentication {kerberos   ntlm   ntlmv2}<br/>host <i>ip-address</i> [<i>spn spn</i>]<br/>[<i>user user-name windows-domain domain</i>   <i>proxy-user proxy</i>]</b>                                                                                                                                                                                                                                                                    |

**kerberos | ntlm | ntlmv2** chooses the authentication protocol to test.

**ip-address** identifies the filer or Domain Controller (DC).

**spn** (optional, 1-256 characters) identifies the filer by its Service-Principal Name (SPN). Use this option for a Windows cluster; use the SPN that is shared between the cluster nodes, if there is one. If there is a "\$" at the end of the SPN name, omit it in this command.

**user *user-name windows-domain domain* | proxy-user *proxy*** are credentials to test. The ARX uses this identity to authenticate with the filer(s).

**user *user-name*** (1-64 characters) and **windows-domain *domain*** (1-1024 characters) comprise a valid Windows user and domain name. If you are probing Kerberos authentication, use an FQDN for the **domain** name. The CLI prompts for the user's password after you enter the command.

**proxy-user *proxy*** (1-32 characters) is an already-configured **proxy-user** with permissions to access the filer(s). Use [show proxy-user](#) for a list of proxy users. For a Kerberos probe, the **windows-domain (*gbl-proxy-user*)** for the proxy user must be an FQDN.

|                                 |                                                                                                                         |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax: Configured Filer</b> | <b>probe authentication {kerberos   ntlm   ntlmv2}<br/>external-filer <i>ext-filer-name</i> proxy-user <i>proxy</i></b> |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------|

**external-filer *ext-filer-name*** (1-64 characters) identifies an external filer that has already been configured on the ARX. For a list of configured external filers, use [show external-filer](#).

The remaining options are explained above.

---

**Guidelines** This command applies only to back-end shares that support CIFS.

The output contains the following fields:

**IP address** is the address used to connect to the filer.

**SPN** is the Service-Principal Name used in the CIFS connection.

**User** is the Windows username used for authentication.

**Protocol** is the authentication protocol, chosen in the command.

**Status** is "STATUS\_SUCCESS" if the authentication succeeded, or an error otherwise.

You can use this command to test authentication methods in your Windows network. The [show exports](#) and [probe exports](#) commands are tests to qualify share(s) for inclusion in a namespace.

You can also use this command to test a configured filer that seems to be malfunctioning. The [show namespace](#) command has error messages that sometimes suggest failures at the filer; this command can help to isolate the failure(s).

**Samples** `bstnA# probe authentication ntlmv2 host 192.168.25.20 proxy-user  
acoProxy2`

```
IP address : 192.168.25.20
SPN : VM-SWP2003s2-04@MEDARCH.ORG
User : MEDARCH\jqpublic
Protocol : NTLMv2
Status : STATUS_SUCCESS
```

tests NTLMv2 authentication against a back-end filer at 192.168.25.20. The proxy user, "acoProxy2," authenticated successfully through NTLMv2.

`bstnA# probe authentication kerberos external-filer fs1 proxy-user  
acoProxy2`

```
IP address : 192.168.25.20
SPN : vm-swp2003s2-04$@MEDARCH.ORG
User : jqpublic@MEDARCH.ORG
Protocol : Kerberos
Status : STATUS_SUCCESS
```

tests Kerberos authentication on a host that has been defined as an external filer, fs1. This uses the credentials defined for a proxy-user, "acoProxy2."

[probe exports](#)

## probe exports

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                                    | The ARX independently migrates files from one back-end filer to another, and requires credentials with adequate permissions to do so. Use the <b>probe exports</b> command to test your Windows credentials (or test Unix <i>root</i> credentials) against a filer. The test attempts to write and delete a file at each of the filer's shares. This is useful for qualifying the shares for inclusion in an external filer, or for troubleshooting filer shares that are already used in a namespace. |
| <b>Mode</b>                                       | priv-exec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Security Role(s)</b>                           | crypto-officer or storage-engineer                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax:</b><br><b>Not-Yet Configured Filer</b> | <b>probe exports host {<i>ip-address</i>   <i>hostname</i>} [<i>spn spn</i>]<br/>[<i>share share-name</i>] [<i>user user-name windows-domain domain-name</i>  <br/>proxy-user <i>proxy</i>]</b>                                                                                                                                                                                                                                                                                                        |

*ip-address* | *hostname* (1-1024 characters) identifies the filer. To use a *hostname*, the switch must be configured to perform DNS lookups; refer to the [ip name-server](#) documentation for instructions.

*spn* (optional, 1-256 characters) identifies the filer by its Service-Principal Name (SPN). Use this option for a Windows cluster; use the SPN that is shared between the cluster nodes, if there is one. If there is a "\$" at the end of the SPN name, omit it in this command.

*share-name* (optional, 1-1024 characters) identifies one share on the filer.

**user *user-name windows-domain domain-name* | proxy-user *proxy*** are Windows credentials to test. If you omit these options, the command uses *root* as its identity and probes for Unix/NFS permissions. The ARX uses this identity to authenticate with the filer(s), for permission to probe the shares.

**user *user-name*** (1-32 characters) and **windows-domain *domain-name*** (1-1024 characters) comprise a valid Windows user and domain name. The CLI prompts for the user's password after you enter the command.

**proxy-user *proxy*** (1-32 characters) is an already-configured [proxy-user](#) with permissions to access the filer(s). Use [show proxy-user](#) for a list of proxy users.

|                                 |                                                                                                                                                                          |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax: Configured Filer</b> | <b>probe exports external-filer <i>ext-filer-name</i> [<i>share share-name</i>]<br/>[<i>user user-name windows-domain domain-name</i>  <br/>proxy-user <i>proxy</i>]</b> |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**external-filer *ext-filer-name*** (1-64 characters) identifies an external filer that has already been configured on the ARX. You can use **all** to probe all configured filers. For a list of configured external filers, use [show external-filer](#).

The remaining options are explained above.

**Guidelines** The output lists all CIFS shares or NFS exports, depending on whether or not you used Windows credentials (*user-name* or *proxy*), and examines the access privileges at each of them. For CIFS shares, it performs a write test using the credentials of the *user-name* or *proxy* user. It also verifies that the user or proxy user has adequate permissions at the filer, equivalent to those of a Backup Operator. The results of these two tests, labeled **Write** and **Privs**, must be “OK” for the user or proxy user. For NFS shares, it performs a mount test as the Unix *root* user; the mount must succeed for NFS shares.

You can use this command to qualify a filer’s shares before including them in a namespace. The `show exports` command runs some less-intrusive tests to qualify the share(s). For a share that passes all tests, you can use `filer`, a `gbl-ns-vol-shr` command, to include the share in a namespace.

You can also use this command to test a configured filer that seems to be malfunctioning. The `show namespace` command has error messages that sometimes suggest failures at the filer; this command can help to isolate the failure(s).

To test various CIFS-authentication methods against a filer, use the `probe authentication` command.

**Samples** `bstnA# probe exports host 192.168.25.20 share histories user jqpublic windows-domain MEDARCH.ORG`  
 Password: `jqpasswd`

runs a security test on one CIFS shares at 192.168.25.20. See [Figure 20.1 on page 20-23](#) for sample output.

`bstnA# probe exports external-filer nas1 share insurance proxy-user acoProxy2`

runs the same test on a host that has been defined as an external filer, `nas1`. This uses the credentials defined for a proxy-user, “`acoProxy2`.” For sample output, see [Figure 20.2 on page 20-24](#).

`prtlnDA# probe exports external-filer das-p2`

runs an NFS-security test on another filer, `das-p2`. This uses *root* as its identity. For sample output, see [Figure 20.3 on page 20-24](#).

---

## proxy-user (gbl-filer)

**Purpose** Use this command to assign SSH, RSH, or WinRM credentials (username and password) for the current filer. The ARX uses these credentials to log into the filer's management CLI/API and run snapshot or checkpoint commands. The ARX can also use these credentials to find physical paths (as opposed to virtual, shared paths) for storage in a [file-history archive](#).

Use the `no` form of the command to remove the proxy-user configuration from this filer. This prevents any ARX volume from using this filer for snapshots, or for finding physical paths on this filer for its file-tracking records.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `proxy-user name`  
`no proxy-user`

*name* (1-32 characters) is the proxy user to use for accessing the filer's CLI.

**Default(s)** None

**Guidelines** From gbl mode, use the [proxy-user](#) command to add a proxy-user configuration to the ARX. Use the [show proxy-user](#) command to view all configured proxy-users and their associated usernames.

### ◆ Note

---

*This has no relationship to the [proxy-user \(gbl-ns\)](#) command, which a namespace uses for policy-driven migrations. This command supports CLI logins, and the [gbl-ns](#) command supports policy migrations. You must assign both types of proxy users to support both features.*

This proxy user does not require a Windows domain for a NetApp or EMC device, where it is only used for SSH or RSH access to the Unix CLI, but it requires an FQDN (such as "mydomain.myc.com") for a Windows server. The ARX uses Kerberos to authenticate with a Windows server, and Kerberos requires FQDNs.

**Guidelines: Snapshot Support** You must use this command to prepare the filer for coordinated-snapshot support with a [snapshot rule](#). Additionally, you must use [filer-type](#) to identify the vendor of the current filer and [manage snapshots](#) to confirm that the filer supports snapshots. You can also use the [ip address ... management](#) command to specify a management IP for accessing the CLI (by default, the ARX volume uses the primary-IP address).

**Guidelines:** You should also use this command for a managed volume that is tracking its files. This type of managed volume has a snapshot rule with special **contents**: the volume's configuration and possibly its metadata. The rule stores these regularly on an external **archive**. With these options in place, you can query the archive for the volume's file paths at different times. Use the **show virtual path-history** and **show file-history virtual-service** commands for these queries. These queries can tell you a file's location yesterday, when you may have performed an incremental backup on your filers, and today, when the managed volume may have migrated the file to a new filer according to your administrative policies.

To find the physical paths for display in the above queries, the snapshot rule accesses the volume's backing-filer through its CLI or API. Every filer behind the managed volume needs this assignment, or the physical paths may be blank in those queries. The volume does not have to manage snapshots, but it does need the **filer-type**.

**Samples** `bstnA(gbl-filer[nas10])# proxy-user nas_admin`  
uses proxy user "nas\_admin" for CLI-login credentials at the "nas10" filer.

`bstnA(gbl-filer[das2])# no proxy-user`  
removes any CLI-login credentials designated for the "das2" filer. This means that the filer cannot support coordinated snapshots.

**Related Commands** [proxy-user](#)  
[show proxy-user](#)  
[snapshot rule](#)  
[filer-type](#)  
[manage snapshots](#)  
[ip address ... management](#)  
[file-history archive](#)

## show exports

|                                                   |                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                                    | Use the <code>show exports</code> command to examine back-end filers that may or may not be configured as external filers. This command is useful for qualifying a filer's shares for inclusion in an external filer, or for troubleshooting filers that are already used in a namespace. |
| <b>Mode</b>                                       | (any)                                                                                                                                                                                                                                                                                     |
| <b>Security Role(s)</b>                           | operator                                                                                                                                                                                                                                                                                  |
| <b>Syntax:</b><br><b>Not-Yet Configured Filer</b> | <code>show exports host {<i>ip-address</i>   <i>hostname</i>} [<i>spn spn</i>]<br/>[<i>share share-name</i>]<br/>[<i>connectivity capabilities shares time attributes paths</i>]<br/>[<i>user user-name windows-domain domain-name</i>  <br/><i>proxy-user proxy</i>]</code>              |

*ip-address* | *hostname* identifies the filer. (To use a *hostname*, the switch must be configured to perform DNS lookups. Refer to the [ip name-server](#) documentation for instructions.)

*spn* (optional, 1-256 characters) identifies the filer by its Service-Principal Name (SPN). Use this option for a Windows cluster; use the SPN that is shared between the cluster nodes, if there is one. If there is a "\$" at the end of the SPN name, omit it in this command.

*share-name* (optional, 1-1024 characters) identifies one share on the filer.

**connectivity** | ... | **paths** selects a particular topic for examination; if you omit this, several of these topics are examined. Each topic generates a different table with its results. See the *Guidelines*, below, for details about each table.

**user *user-name windows-domain domain-name* | proxy-user *proxy*** is a required choice for either of the following tests on a CIFS filer: **shares** or **attributes**. If you omit both of these options, the command only probes for NFS services and attributes. The ARX uses this identity to authenticate with the CIFS filer(s), for permission to examine the shares.

**user *user-name*** (1-32 characters) and **windows-domain *domain-name*** (1-1024 characters) is a valid Windows user and domain name. The CLI prompts for the user's password after you enter the command. The domain name must be an FQDN (that is, "thisdomain.thatdomain.com" as opposed to "thisdomain") to test Kerberos authentication.

**proxy-user *proxy*** (1-32 characters) is an already-configured [proxy-user](#) with permissions to access the filer(s). Use [show proxy-user](#) for a list of proxy users. As above, the proxy user's domain must be fully-qualified for the command to use Kerberos authentication.

**Syntax: Configured Filer** `show exports external-filer ext-filer-name [share share-name] [connectivity | capabilities | shares | time | attributes | paths] [user user-name windows-domain domain-name | proxy-user proxy]`

**external-filer *ext-filer-name*** identifies an external filer that has already been configured on the ARX. You can use **all** to show all configured filers. For a list of configured external filers, use [show external-filer](#).

The remaining options are explained above.

**Guidelines** This command shows several tables that indicate whether or not a filer's shares can be used in a namespace. Use this together with [probe exports](#), which runs a write test to verify that your Windows credentials are adequate for CIFS shares.

To test various CIFS-authentication methods against a filer, such as Kerberos, use the [probe authentication](#) command.

You can use this command to qualify a filer's shares before including them in a namespace volume. For a share that passes all tests, you can use [filer](#), a `gbl-ns-vol-shr` command, to include the share in a volume.

You can also use this command to test a configured filer that seems to be malfunctioning. The [show namespace](#) command has error messages that sometimes suggest failures at the filer; this command can isolate the failure(s).

If you use any Windows credentials (**user/windows-domain** or **proxy-user**), the command ignores NFS shares, capabilities, and time. If you omit Windows credentials, the command focuses exclusively on NFS.

---

**Guidelines: Output  
Format**

Connectivity indicates whether or not the ARX can ping the filer IP from each of its proxy-IP addresses. The ARX sends multiple pings from each proxy-IP, each with a different-sized packet, to ensure that the MTU size is consistent between the proxy IP and the filer. All pings must succeed from *all* proxy IPs for the filer to be usable. For the pings to succeed, the filer must reside on the same subnet as the proxy IPs, or be reachable through a static route (where the next-hop router is on the proxy-IP subnet). Use [ip proxy-address](#) to establish the proxy-IP subnet. Use [ip route](#) to add a static route. Additionally, all switches and network equipment between the ARX and filer must have consistent MTU settings; use [jumbo mtu](#) to set the MTU at an ARX VLAN.

CIFS Credentials are the credentials presented to the back-end filer for authentication. This is a table with three fields: **User name**, **Windows Domain**, and **Pre-Win2k domain**. Use the **user** and **windows-domain** options to set these, or the **proxy-user** option. The **Pre-Win2k domain** is only used for NTLM authentication: if you previously ran [active-directory update seed-domain](#), this was automatically discovered; if not, and you specified a **user** in the command, this is the first part of the Domain's FQDN; if you specified a **proxy-user**, someone can explicitly set this with an option in the [windows-domain \(gbl-proxy-user\)](#) command. If the credentials were omitted from the command, "anonymous" appears in the **User** field.

Capabilities shows the NFS or CIFS services available at the filer:

NFS lists the three services required for NFS, one per row. Each service shows the protocol and version used for transport (TCP vs. UDP), along with the port number where the service is listening.

CIFS also shows some server-level security settings, whether or not the ARX can connect to the IPC\$ share on the filer, and the authentication method (NTLM, NTLMv2, or Kerberos) used for the **user** or **proxy-user** in the command. For Kerberos authentications, the Windows domain for the user or proxy user must be an FQDN.

**Guidelines: Output  
Format (Cont.)**

Shares lists all the NFS or CIFS shares, each in its own table:

NFS shows the results of two tests on each share, one share per row.

- **Path (Owner)** is the export path at the back-end filer.
- **Status** is “Mounted” if the ARX succeeded in mounting the export from each of its proxy-IP addresses. The share is only usable in a namespace if the mounts succeed from all of the proxy IPs. The list of proxy IPs appears in the **Connectivity** section of this report. If any mount fails, this shows the error returned from the filer in place of all fields in the row.
- **Read Size** and
- **Write Size** are the negotiated NFS-read size and NFS-write size.
- **Space Total** and **Avail** are the total and free space reported by the filer.
- **FSID** is the file-system ID reported by the filer. This identifies the back-end storage volume behind this NFS export. Any two exports with the same FSID draw from the same storage pool, so their space sizes (above) match.
- **Access** shows the IP address(es) or NIS group(s) that are authorized to access this share. A “\*” or “(everyone)” indicates that any client machine can access the share.

CIFS displays the disk space on the share and the serial number for the share’s storage volume. Any two shares with the same serial number draw from the same storage pool, so their disk-space numbers match.

**Time** shows the current time at the filer. The skew field at the end of the output shows the skew between the filer’s clock and that of the ARX. The time settings must be nearly synchronized (preferably through NTP; see [ntp server](#)) for time-based policies to function.

**Attributes** shows each CIFS share and its CIFS attributes. If all of the shares behind an ARX volume support one of these attributes, the volume can support it, too. You can set each CIFS attribute for a volume with [cifs access-based-enum](#), [compressed-files](#), [named-streams](#), [persistent-acls](#), [sparse-files](#), or [unicode-on-disk](#), respectively. The attribute settings are either X, -, or ?.

- “X” means that the back-end share supports this attribute.
- If “-,” the share does not support this CIFS attribute.
- A “?” indicates that the ARX was unable to run the test for some reason. This can occur if the Windows credentials are insufficiently privileged for the query; for example, the **user** or **proxy-user** must have Administrator-level privileges to test for ABE.

**Paths** is another option for CIFS shares; this shows the physical disk and path at the root of each CIFS share. Each row contains a CIFS-share name and a path. This is useful for finding and verifying share-to-subshare relationships; see the documentation for [filer-subshares](#). This command requires Administrator-level access to read the directory path for each share; this is an increase from the usual requirements for a **user** or **proxy-user**. You can therefore use the **paths** option to verify that the **user** or **proxy-user** belongs to the Administrator group on the target filer.

- Samples** bstnA> **show exports host 192.168.25.21 user jqpublic windows-domain MEDARCH.ORG**  
 Password: **jqpasswd**  
 shows export information for all CIFS shares on 192.168.25.21. See [Figure 20.4 on page 20-31](#) for sample output.
- bstnA> **show exports host 192.168.25.19 connectivity**  
 shows only the Connectivity table for another filer. See [Figure 20.5 on page 20-32](#) for sample output.
- bstnA> **show exports external-filer fs1 capabilities proxy-user acoProxy2**  
 shows the Capabilities for a CIFS filer, fs1. For sample output, see [Figure 20.6 on page 20-33](#).
- bstnA> **show exports host 192.168.25.19 time**  
 shows the filer's time. See [Figure 20.7 on page 20-33](#) for sample output.
- bstnA> **show exports host 192.168.25.29 paths proxy-user acoProxy2**  
 shows the physical paths for every CIFS share at 192.168.25.29. See [Figure 20.8 on page 20-33](#) for sample output, which shows a share and three subshares on the back-end filer.

**Related Commands** [show external-filer filer](#)

## show external-filer

**Purpose** Use the `show external-filer` command to display summary or detailed information about the external filers connected to the ARX.

**Mode** (any)

**Security Role(s)** operator

**Syntax** `show external-filer`  
`show external-filer filer-name`  
`show external-filer all`

If no filer name is specified, this command shows IP addresses for all external filers.

*filer-name* (optional; 1-64 characters) identifies a specific filer. This shows a detailed report for the filer.

**all** (optional) shows detailed reports for all external filers.

**Guidelines: Summary** The summary form shows a table with one row per external filer. The table contains three columns:

**Name** is set with the `external-filer` command.

**IP Address** shows the filer's address. You can reset this with `ip address`.

**Description** is the string set with the `description (gbl-filer)` command. The flag "(*n*th secondary)" appears here for filers with multiple IP addresses; this marks one of the filer's secondary addresses (see `ip address`).

**Guidelines: Detailed** The detailed form shows all configuration information for the external filer, followed by a series of tables that describe how the ARX is using the filer. The configuration information includes these fields:

**Description** is the string set with the `description (gbl-filer)` command.

**Filer IP** is/are the filer's address(es). You can use the `ip address` command to change this list of addresses.

**Filer IP (new)** only appears if someone designated a new primary address for this filer. This becomes the filer's primary IP address the next time the ARX reboots or fails over. You can use the `ip address ... change-to` command to change this new address.

**Configured SPN** only appears if someone used `spn` to set a service-principal name (*SPN*) for the external filer. The ARX needs the correct SPN for Windows clusters and for Kerberos support. If this appears, the ARX is always using it (not the **Discovered SPN**, below) for cluster connections and Kerberos authentications.

**Discovered SPN** is the SPN returned from a filer query. The filer query occurs when the filer's first share is enabled in a managed `volume`. If the **Configured SPN** is set, the ARX does not use this SPN in its cluster connections or Kerberos authentications. "Not Discovered" appears here if there is neither a configured SPN or a successfully-discovered SPN.

**Guidelines: Detailed  
(Cont.)**

Filer Management Proxy User identifies the Unix [proxy-user](#) credentials that the ARX uses to access the filer's CLI, where the ARX software issues snapshot commands. You can use the [proxy-user \(gbl-filer\)](#) command to select a different proxy user.

Filer Management IP is a separate management-IP address, for filers that support an out-of-band IP for management. The ARX logs into the filer's CLI through this address. You can use the [ip address ... management](#) command to reset it.

Filer Manage Snapshots is "Yes" if the ARX is permitted to run snapshots on the filer, or "No" otherwise. To change this setting, use the [manage snapshots](#) command.

CIFS Port is port that the ARX uses to make its CIFS connections. The ARX can automatically choose between the two well-known ports, 445 and 139, or you can set it explicitly with the [cifs-port](#) command.

CIFS Connection Limit Overall is the maximum number of CIFS/TCP connections to the filer. Use the [cifs connection-limit](#) command to set this maximum.

CIFS Connection Limit / NSM Processor is the maximum number of CIFS/TCP connections per NSM.

NFS TCP Connections is the number of NFSv3/TCP connections to the filer. This is typically 1, but you can set a higher number before you incorporate the share into a managed volume. Use the [nfs tcp connections](#) command to set this number.

These next fields only appear only if their respective values are set:

- **Filer Type** is "Network Appliance," "EMC," "Data Domain," or "Windows," set with the [filer-type](#) command. The word "(explicit)" appears after the vendor name, to indicate that the command explicitly named the vendor for this filer.
- **Windows Cluster** only appears if you use the [cluster](#) option in the [filer-type](#) command. If this appears, the ARX uses snapshot commands on this filer that are formatted for a Windows server 2008 (or later) cluster.
- **Management Protocol** is the protocol the ARX follows to access the filer's management API: SSH or RSH for NetApp, or WINRM for Windows. To change this protocol for a NetApp filer, use the [management-protocol](#) option in the [filer-type](#) command.
- **NAS DB Path** applies to an EMC Celerra server whose environment variable, `NAS_DB`, has a non-default value. The ARX requires the exact value of this variable to invoke checkpoints at the file server. Most EMC servers use the default; for those that do not, you can use an option with the [filer-type](#) command to indicate the non-default value. This field does not appear unless someone has set a non-default `NAS_DB` path. with the [filer-type](#) command.
- **Management Port** is the WinRM port that the ARX uses to manage snapshots. This presumes that the back-end filer is a Windows server. This field only appears if you set the [port](#) option in the [filer-type](#) command.

**Guidelines: Managed Exports Table**

Managed Exports is the list of filer shares that are used in managed volumes (as opposed to direct volumes). This table only appears if one of the filer's shares is imported into a managed volume.

NFS Export or CIFS Share is the name of the export or share at the back-end filer. A CIFS filer may export "ipc\$," a standard CIFS share, if an ARX namespace uses it as a [sam-reference](#) filer.

- Namespace and
- Volume identify the managed volume that uses this share.

Automatically Striped Subshares is a list of CIFS subshares that a managed volume has created on this filer. You can configure a managed volume to pass a CIFS client from a front-end subshare directly to one of its corresponding back-end subshares, where the back-end filer can subject the client to the correct share-level ACL. To support this feature, some volumes replicate, or *stripe*, subshares between their filer shares. You can use the [filer-subshares](#) command to make a volume stripe its subshares.

(restore data share) appears for a share that has been used in a [restore data](#) operation, and is not assigned to any namespace.

(file-history archive location) appears for a share that is used as a [location](#) for a [file-history archive](#), and is not assigned to any namespace.

(contains no metadata) indicates that the share is unused. It is not assigned to any namespace, nor is it used in a file-history archive, nor has it ever been used in a [restore](#) operation.

**Guidelines: Replica-snap Exports Table**

Replica-snap Exports is the list of [replica-snap](#) shares, which are also used in managed volumes. This table only appears if one of the filer's shares is used as a replica-snap share.

NFS Export or CIFS Share is the name of the export or share at the back-end filer.

- Namespace and
- Volume identify the managed volume that uses this replica-snap share.

**Guidelines: Directories to Ignore**

Directories and/or files to ignore for importing shows all directories/files to ignore during the import. You can use the [ignore-name](#) command to identify these names.

---

**Guidelines: Direct  
Mapped Exports Table**

Direct Mapped Exports appears only if at least one of the filer's shares is used in a [direct](#) volume. Each share in a direct volume has one or more virtual directories, called *attach points*. Each attach point is directly mounted (or mapped) to one path on a back-end share. When a client lists files in an attach point, he sees the contents of the physical directory at the back-end share.

**Backend Path** is the absolute path to the root of the back-end share. This is established by the [filer](#) command in gbl-ns-vol mode.

**Namespace and**

**Volume** identify the direct volume that uses this share.

**Protocols** are the namespace protocols, all of which must be supported by this back-end share. Use the gbl-ns [protocol](#) command to establish these for the namespace.

**Volume Path** is one of the direct volume's attach-point directories. Clients see this path under the **Volume** path, above. The [attach](#) command creates it.

**Filer-Path** is the actual filer directory to which the volume is attached. This is relative to the **Backend Path** described earlier. The [attach](#) command attaches the **Volume Path** to this real path.

**Guidelines:  
Metadata-only Shares**

Metadata-only shares are back-end shares devoted to managed-volume metadata. Use the [metadata share](#) command to add one of these to a namespace or volume. This table only appears if the filer is hosting at least one metadata-only share. It shows the same information as the **Managed Exports** table.

- Samples** `bstnA> show external-filer`  
shows IP addresses for all the external filers configured for storage. See [Figure 20.9](#) for sample output.
- `bstnA> show external-filer das1`  
shows details about the external-filer named “das1.” See [Figure 20.10 on page 20-39](#) for sample output.
- `bstnA> show external-filer fs2`  
shows details about a CIFS filer named “fs2,” where a managed volume has automatically striped some filer subshares. See [Figure 20.11 on page 20-39](#) for sample output.
- `bstnA> show external-filer nas2`  
shows details about the external-filer named “nas2,” which has direct exports for a direct volume. See [Figure 20.12 on page 20-40](#) for sample output.
- `bstnA> show external-filer nas10`  
shows details about the external-filer named “nas10,” which supports ARX snapshots. See [Figure 20.13 on page 20-41](#) for sample output.
- `bstnA> show external-filer nas11`  
shows details about the external-filer named “nas11,” which is the host for replica-snap shares. See [Figure 20.14 on page 20-41](#) for sample output.
- `prt1ndA> show external-filer all`  
shows details about all external-filers configured at another switch, “prt1ndA.” See [Figure 20.15 on page 20-43](#) for sample output.

## spn

**Purpose** The ARX attempts to automatically discover a filer's service-principal name (*SPN*) when the filer's first share is enabled in a managed volume. A Windows server in a cluster may provide its local SPN instead of the SPN for the cluster; you can use the `spn` command to manually set the cluster SPN. This setting overrides any previously-discovered SPN.

The auto-discovery method does not work for a Windows 2008 cluster, so this command is required for that server type. It is also required for a Windows 2003 cluster: the ARX needs a Windows 2003 cluster's shared SPN to support cluster failovers.

Use the `no` form of this command to revert to the discovered SPN, if there is one.

**Mode** gbl-filer

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `spn hostname@domain`  
`no spn`

*hostname@domain* (1-256 characters) is the SPN for the external filer. Do not use any "\$" or "/" characters.

*hostname* is the filer's hostname, or the Cluster Network Name.

@ is required, and it must be between the hostname and the domain. There can only be one "@" symbol in the SPN.

*domain* must be in FQDN format (for example, "ourdiv.ourco.com" instead of simply "ourdiv").

**Default(s)** (the discovered SPN, if there is one)

**Guidelines: Windows Clusters** A Windows 2008 cluster only supports connections to a name (as opposed to an IP address). The SPN contains the name of the virtual service, and is therefore required for any Windows 2008 cluster. You must manually set the SPN for a Windows 2008 cluster, which does not provide the data necessary to perform an automatic SPN discovery. You must also set the SPN for a Windows 2003 cluster, so that the ARX can stay connected across a cluster failover.

For any cluster, this SPN must be a *virtual SPN*, one that persists after a cluster failover. Therefore, you must create a virtual SPN on the cluster before using the cluster's storage behind the ARX. This may mean joining the cluster's virtual service to the local AD domain.

---

**Guidelines: Kerberos Support**

For other server types, the correct SPN is required for Kerberos authentications. If the SPN is incorrect, a managed volume's [proxy-user](#) cannot connect and cannot import the filer's shares.

The [show external-filer](#) command shows the discovered SPN for the filer. If this is empty or incorrect, you can use the `spn` command to override the discovery. Once you use the `spn` command, the `show external-filer` output contains two SPN values: the discovered SPN and your configured SPN.

For an external filer without a discovered SPN, the `no spn` command ensures that the volume cannot use Kerberos authentication with this filer. A CLI prompt warns you of this; enter **yes** to proceed.

**Guidelines: SPN Changes When Filer's Hostname Changes**

If the back-end filer changes its hostname, its SPN also changes. Invoke this command again to establish the new SPN after the filer name changes. Until the SPN is updated, no managed volume can perform autonomous operations on the filer, such as importing files and migrating them to or from one of the filer's shares, and CIFS clients have limited access through Kerberos.

**Samples**

```
bstnA(gbl-filer[fs3])# spn fs3@medarch.org
sets a SPN for the "fs3" external filer.
```

```
bstnA(gbl-filer[fs1])# no spn
```

The ARX cannot discover the service principal name for the filer. Removal of the configured service principal name may prevent use of Kerberos authentication when connecting to the filer.

```
Proceed? [yes/no] yes
```

reverts to the discovered SPN for the filer.

Namespace

---

## character-encoding nfs

**Purpose** *Character encoding* is the mapping between binary numbers and written characters. Some character-encoding schemes use only a single byte for each character; these typically support alphabets without any Asian characters. Multi-byte encoding schemes encompass Asian character sets. Unicode (such as UTF-8) can also use more than one byte per character, and encompasses most character sets and languages. Use the `character-encoding` command to set the namespace's character encoding for NFS file names.

Use `no character-encoding` to reset NFS file names back to the single-byte default.

**Modes** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `character-encoding nfs {utf-8 | shift-jis | cp932 | euc-jp  
| ksc5601 | iso-8859-1}`  
`no character-encoding nfs`

**utf-8** specifies UTF-8 (Unicode) character encoding.

**shift-jis** specifies Shift\_JIS (Japanese) character encoding.

**cp932** is Code Page 932, or Windows-31J (Japanese) character encoding. This is the Microsoft version of Shift\_JIS.

**euc-jp** specifies EUC-JP (Extended Unix Code - Japanese) character encoding.

**ksc5601** is KSC5601 (Korean) character encoding.

**iso-8859-1** is ISO 8859-1 (Latin1, single-byte) character encoding.

**Default(s)** ISO 8859-1 (Latin1)

**Guidelines** NFS character encoding determines the character encoding for file names. Any NFS server and client must be set for the same NFS character encoding to communicate properly. The NFS character encoding should be well-established at any site before the ARX is installed.

CIFS uses Unicode, which can support any character set, so it does not require this command.

A multi-protocol (NFS and CIFS) namespace does not allow a CIFS client to name a file or directory with characters that are not supported by NFS character encoding. If NFS names support only single-byte characters, the namespace enforces the same restriction on CIFS names. During the initial import of multi-protocol shares, the volume uses the NFS-side name of each file (possibly a filer-generated name), and renames each directory so that it is valid in NFS. (You can use `no import rename-directories` to prevent directory renames on import.) We recommend UTF-8 character encoding for multi-protocol namespaces and the filers behind them.

The `no` form of the command returns the namespace to default character encoding.

If a single front-end `nfs` service has exports from more than one namespace, this setting must be the same for all of the exported namespaces. The `export (gbl-nfs)` command exports a namespace volume through NFS.

**Sample** `bstnA(gb1-ns[wwmed])# no character-encoding nfs`  
resets the character encoding for NFS file names to the default.

---

## cifs anonymous-access

**Purpose** Some scanners and photocopiers have a “Save As” feature that allows the client to save a copy of a scanned file onto a remote CIFS server. Many scanners and copiers make queries to the CIFS server’s hidden IPC\$ share before they save the file. These devices make their queries as the “anonymous” Windows-user account. To allow anonymous queries to the current namespace’s IPC\$ share, use the `cifs anonymous-access` command.

Use `no cifs anonymous-access` in a namespace that does not support connections to the IPC\$ share.

**Modes** `gbl-ns`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `cifs anonymous-access`  
`no cifs anonymous-access`

**Default(s)** `no cifs anonymous-access`

**Guidelines** This command does not apply to an NFS-only namespace.

There are only a small set of photocopiers that require this access before they save files to the namespace. The *F5 Data Solutions Compatibility Matrix* (included with this doc set) lists all the photocopiers that are known to require this feature.

The `cifs anonymous-access` command permits anonymous queries to the virtual IPC\$ “share,” but does not permit scanners and photocopiers to actually save files to any of the namespace’s volumes. As always, the scanner/copier must provide a valid Windows username and password to perform the file-save operation.

Certain CIFS-client operating systems, such as Mac OS X v10.4, also require anonymous access to make certain queries.

If a single front-end `cifs` service has exports from more than one namespace, this setting must be the same for all of the exported namespaces. (The `export (gbl-cifs)` command exports a namespace volume through CIFS.) Therefore, if this command makes the current namespace inconsistent with the other namespace(s) behind the same CIFS service, the CLI prompts with an opportunity to make the same change in the other namespace(s). Enter `yes` to allow the CLI to propagate the change to the other namespace(s).

**Samples** `provA(gbl-ns[provMed])# cifs anonymous-access`  
 allows certain scanners and copiers to perform anonymous queries in the “provMed” namespace. This is a necessary first step to supporting the “Save As” feature from those scanners.

`bstnA(gbl-ns[insur])# no cifs anonymous-access`  
 Synchronize conflicting parameter(s) for all the namespaces exported along with this namespace in a service and continue? [yes/no] `yes`  
 denies any anonymous access to the IPC\$ share in the “insur” namespace. Scanners and copiers cannot save files to volumes in this namespace. The CLI also disables this option in all other namespaces behind the same CIFS service.

| <b>Security Role(s)</b>            | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Syntax</b>                      | <code>cifs authentication {kerberos   ntlm   ntlmv2}</code><br><code>no cifs authentication {kerberos   ntlm   ntlmv2}</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default(s)</b>                  | all CIFS-authentication protocols are disabled by default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Guidelines</b>                  | <p>This applies only to namespaces that support CIFS.</p> <p>You can run this command once for each supported protocol. A namespace can support all three authentication protocols, or any combination of them.</p> <p>Each CIFS client negotiates an authentication protocol from this set. The protocol is chosen during the client-side negotiation.</p> <p>CIFS clients access namespace storage through a front-end CIFS service. If a single CIFS service has exports from more than one namespace, the authentication settings must be the same for all of the exported namespaces. (The <code>export (gbl-cifs)</code> command exports a namespace volume through CIFS.) Therefore, if this command makes the current namespace inconsistent with the other namespace(s) behind the same CIFS service, the CLI prompts with an opportunity to make the same change in the other namespace(s). Enter <b>yes</b> to allow the CLI to propagate the change to the other namespace(s).</p> |
| <b>Guidelines: Kerberos</b>        | The namespace's front-end CIFS service must join a Windows domain to support Kerberos authentication. Use the <code>domain-join</code> command to enable Kerberos for a front-end <code>cifs</code> service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Guidelines: NTLM and NTLMv2</b> | The <code>domain-join</code> command can also enable a CIFS service for NTLM or NTLMv2. If you (or an authorized Domain Administrator) go to the domain controller (DC) and set up constrained delegation for the CIFS service, clients can authenticate with NTLM, NTLMv2, or Kerberos. No further configuration is required. In this case, the namespace software connects to its back-end filers with Kerberos, whether or not the client uses a variant of NTLM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Guidelines: Secure Agent**

A CIFS service that is configured for unconstrained delegation, or is not even joined to its domain, requires more configuration to support NTLM or NTLMv2. For these configurations, you must install an application onto one or more DCs. This DC application, called the *Secure Agent*, enables the namespace to authenticate a client once and then access storage on multiple back-end filers. See the *ARX Secure Agent Installation Guide* for instructions on installing a Secure Agent onto a DC. Then you can use [ntlm-auth-server](#) and [ntlm-auth-server \(gbl-ns\)](#) to connect the namespace software to the Secure Agent application.

For the namespace to support NTLMv2 as well as NTLM, you must have a version of the Secure Agent software that also supports NTLMv2. This command issues a prompt to inform you of the minimal version required.

If the namespace is configured for both NTLM and NTLMv2, it prefers NTLMv2 in its connections with back-end servers. This is true even for client connections where the client connects through NTLM.

**Samples**

```
bstnA(gbl-ns[ns1])# cifs authentication kerberos
bstnA(gbl-ns[ns1])# cifs authentication ntlmv2
```

```
% INFO: To use NTLMv2 with the Acopia Secure Agent, all agent instances
must support NTLMv2 (requires agent version 5.1.0 or later).
 enables Kerberos and NTLMv2 for clients of the "ns1" namespace.
```

```
bstnA(gbl-ns[insur])# no cifs authentication ntlm
Synchronize conflicting parameter(s) for all the namespaces exported
along with this namespace in a service and continue? [yes/no] yes
 disables NTLM for clients of the "insur" namespace.
```

**Related Commands**

```
namespace
domain-join
ntlm-auth-server
```

## cifs filer-signatures

**Purpose** Use the `cifs filer-signatures` command to enable (or perhaps require) SMB signing between this namespace and the external filers behind it. *SMB signing* is the process of placing a digital signature into each Server Message Block (SMB) exchanged between a CIFS server (each filer) and client (the namespace software). SMB signing prevents man-in-the-middle attacks at the cost of slower performance.

Use `no cifs filer-signatures` to disable SMB signing between the namespace and its filers. This breaks all CIFS communication with any filers that require SMB signing.

**Mode** `gbl-ns`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `cifs filer-signatures [required]`  
`no cifs filer-signatures`

**required** (optional) obligates all CIFS filers to use SMB signing in their communication with the namespace. If any of the namespace's filers refuse to support SMB signing, the namespace cannot make any CIFS connections to the filer.

**Default(s)** `no cifs filer-signatures`

**Guidelines** This applies only to namespaces that support CIFS. Use the `protocol` command to set the file-access protocols for the namespace.

Without SMB signing, the default for the namespace, the namespace cannot access the CIFS storage on any of its filers that require it.

If you use this command with the `required` option, the namespace can only connect to filers that support SMB signing. The namespace refuses to make a CIFS connection to any filer that does not support SMB signatures.

The least-restrictive setting is to enable SMB signing without requiring it (using the `cifs filer-signatures` syntax). The namespace can then connect to any filer, whether it requires or refuses SMB signing. If the namespace software has a choice, it prefers not to use SMB signing for performance reasons.

To control the SMB-signing policy between the ARX and its clients, you can use the `signatures` command in `gbl-cifs` mode. To see the number of filers and/or clients who have used SMB signing, along with some success and failure statistics, use the `show fastpath cifs-signatures` command.

**Samples** `bstnA(gbl-ns[insur])# cifs filer-signatures`  
allows SMB signing for any filer behind the “insur” namespace. If a filer requires SMB signing, the namespace will comply. Otherwise, to improve CIFS performance, the namespace negotiates for no SMB signing.

`bstnA(gbl-ns[ns1])# cifs filer-signatures required`  
requires SMB signing for all filers behind the “ns1” namespace. If any filer behind the namespace refuses SMB signing, the namespace cannot connect to any of its CIFS shares.

`bstnA(gbl-ns[ns4])# no cifs filer-signatures`  
disables SMB signing for the “ns4” namespace. If any filer requires SMB signing for its CIFS connections, the namespace cannot access that filer’s CIFS shares.

**Related Commands** [namespace](#)  
[signatures](#)  
[show fastpath cifs-signatures](#)

## description (gbl-ns, gbl-ns-...)

**Purpose** Use the optional `description` command to set a descriptive string for the current namespace, volume, or share. This appears in the `show namespace` command.  
Use the `no` form of the command to delete the description.

**Modes** gbl-ns  
gbl-ns-vol  
gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-255 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** `no description`

**Guidelines** Either description appears in the output for [show global-config namespace](#) and [show namespace](#).

**Samples** `bstnA(gbl-ns[wwmed])# description "namespace for World-Wide Medical network"`  
specifies a description for the current namespace.

`bstnA(gbl-ns-vol-shr[medarcv~/rcrds~rx])# description "prescriptions since 2002"`  
specifies a description for the current ARX share, "medarcv~/rcrds~rx."

**Related Commands** [namespace](#) -> [volume](#) -> [share](#)  
[show global-config namespace](#)  
[show namespace](#)

---

## enable (gbl-ns, gbl-ns-vol)

**Purpose** Use the `enable` command to activate the current namespace or volume, or its shares. Use `no enable` to stop access to the current namespace or volume.

**Mode** gbl-ns  
gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `enable [shares [take-ownership]]`  
`no enable [shares]`

**shares** (optional) causes all of the namespace's or volume's shares to be enabled.

**take-ownership** (optional) causes the namespace or managed volume to take ownership of all back-end shares. Use this option only if you are sure that the shares are not in active use by a managed volume on another ARX. For example, some sites use filer applications to replicate all data from one site to another; if an ARX had managed volumes at the primary site, the ARX's ownership marker (a file) would be copied to the second site. An ARX at the second site could only import the share if you use the `take-ownership` option. The option has no effect on a [direct](#) volume, or on any direct volumes in the namespace.

### ◆ Important

---

*This option could possibly remove a share from another managed volume that is in service. Use the `take-ownership` option only for cases where some shares are spuriously marked by another ARX. The CLI prompts for confirmation if you use this option; enter `yes` to proceed.*

**Default(s)** Disabled

**Guidelines** You must enable a volume for it to be accessible by clients. When you enable a namespace, the CLI enables all volumes in the namespace.

The `enable` command causes a managed volume to import external files and directories into its shares. For large directory structures, this takes some time. If there are any name collisions, they occur when you issue the `enable` command. The import happens asynchronously; you can monitor its progress with the [show namespace](#) or [show namespace status](#) commands.

◆ **Important**

*For shares backed by NetApp or EMC, you may need to access the filer directly and pre-create some qtrees or EMC tree quotas. This rare configuration issue only occurs if:*

- *this is a managed volume,*
- *you want to support both free-space quotas ([freespace cifs-quota](#)), and*
- *you also want to support [filer-subshares](#) in this volume.*

*In this case, a NetApp share requires one qtree per subshare, and an EMC import share must be an EMC File System with one quota tree per subshare. Pre-create the NetApp qtrees and/or EMC quota trees before you enable the share. See the [Guidelines: Subshare Replication with Free-Space Quotas](#) section of the [filer-subshares](#) documentation.*

**Guidelines (Cont.)** Each volume belongs to a volume group, which shares a memory pool as well as CPU time. The volume group is associated with several resource limits that are enforced as soon as the volume is enabled. Refer to the [volume-group](#) and [reserve files](#) commands for details.

The **no enable** command makes the volume(s) inaccessible to clients. When a volume is disabled, client applications get no response from it. Different applications react to this in different ways; some hang, others log error messages to an internal log. The shutdown is cleaner for your clients if you first perform **no export (gbl-nfs)**, **no export (gbl-cifs)**, and **no browsing** for all NFS and/or CIFS services that export the volume.

**Guidelines: Direct Volume** A *direct volume* is a collection of directory attach points that is easier to configure than a managed volume but does not offer any policy features. Each attach-point directory in the direct volume is attached to an actual directory on a back-end filer. A direct volume keeps no metadata. You use the [direct](#) command to declare a volume to be a direct volume.

The **enable** command does not trigger an import in a direct volume, since there is no metadata to construct. The enable operation is therefore much faster. Also, the **take-ownership** option has no effect on a direct volume.

**Guidelines: Sync Reports** A CIFS volume with [filer-subshares](#) or [cifs access-based-enum](#) enabled performs some additional processing during import. Specifically, the volume software discovers CIFS subshares (shares under the imported shares) and ABE settings, and it makes these settings consistent at every back-end filer. This process produces a report to show its results, named “syncSshrNewStorageReport\_*timestamp*.rpt.” You can use [show reports](#) to get a list of reports, and [show reports report-name](#) to read a particular report.

If the sync-subshare process fails for any reason, you can use the report to diagnose the problem. You can then rerun the sync process with the [sync subshares from-namespace](#) or [sync subshares from-namespace](#) commands.

---

**Samples** `bstnA(gbl-ns-vol[archives~/eng])# enable`  
enables the current volume, “archives~/eng.”

`bstnA(gbl-ns[ns])# enable shares take-ownership`

This command allows the switch to virtualize shares that are used by other Acopia switches.

Allow switch to take ownership of all the shares in this namespace?

[yes/no] **yes**

enables all shares in the current namespace, “ns.” For all managed volumes in the namespace, this takes ownership of any filer shares that appear to be managed by another ARX.

`bstnA(gbl-ns-vol[unused-ns~/vol2])# no enable`

disables the “unused-ns~/vol2” volume. Clients can no longer access this volume.

**Related Commands** [namespace](#)  
[show namespace](#)

## metadata cache-size

**Purpose** Use the `metadata cache-size` command to specify how much cache memory (in MB) to reserve for managed-volume metadata. This size is used for each `volume-group` domain used by the current namespace.

Use the `no` form of this command to revert to the default cache size.

**Mode** `gbl-ns`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `metadata cache-size cache-size`  
`no metadata cache-size`

*cache-size* (64-1750) is the size, in megabytes (MB), of memory to reserve for the current namespace's metadata cache(s).

**Default(s)** 512

**Guidelines** Use this command only under the guidance of authorized F5 personnel.

The total cache requirement is the number of simultaneous file accesses multiplied by the amount of memory required for each file (approximately 300 bytes at press time). The cache size should therefore be small if users access only a small segment of files at a given time, and it should be large if clients access many different files. The proper size for your site can vary widely depending on a number of configuration settings (number of shares per volume, front-end-service configuration, and so forth). In most cases, this can only be determined by experimentation and close monitoring by trained F5 personnel.

Each of the namespace's volume groups has a separate memory cache, shared by all managed volumes assigned to the domain. Use the `volume-group` command to assign a volume to a group.

On the ARX-500, you can increase the maximum number of volume groups. The memory and CPU resources are more scarce on this platform than its newer counterparts, so it is shipped with a lower volume-group maximum. If you increase the maximum number of volume groups (using the `max-volume-groups` command), you should also consult with F5 to change this metadata cache size. The total memory used for this namespace is the total number of volume groups times this cache size. All platforms can use swap space (from their internal disks) to add to memory size if memory gets low. You can use the `show processors usage` command to monitor memory and swap-space usage on the system.

You must disable and re-enable the namespace for this command to take effect; use the `[no] enable (gbl-ns, gbl-ns-vol)` command in `gbl-ns` mode.

**Sample** `bstnA(gbl-ns[wwmed])# metadata cache-size 500`  
allocates 500 MB cache memory for each volume group used by the "wwmed" namespace.

**Related Commands** [enable \(gbl-ns-vol-shr\)](#)  
[volume-group](#)  
[max-volume-groups](#)  
[show global-config namespace](#)  
[show processors usage](#)

## namespace

**Purpose** Use the `namespace` command to create a new namespace, or edit an existing one.  
Use the `no` form of the command to delete a namespace.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `namespace name`  
`no namespace name`

*name* (1-30 characters) is a name you choose for the namespace. The name “all” is reserved and cannot be used.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before creating a namespace; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new objects.)

This places you in `gbl-ns` mode, where you must establish one or more managed volumes and/or direct volumes for the namespace. Each managed volume is like a file system in the namespace; it is composed of files and directories from various back-end filers. A direct volume contains shares with *attach points*, which are analogous to NFS mount points and mapped CIFS shares. A managed volume contains metadata and supports policy rules, a direct volume does not. Use the [volume](#) command to create either type of volume.

From `gbl-ns` mode, you must also set the file-access protocol (NFSv2, NFSv3 (over UDP), and/or CIFS), and you must configure any security parameters to properly authenticate clients. Use the [protocol](#) command to set the file-access protocol(s). Use the [enable \(gbl-ns, gbl-ns-vol\)](#) command to enable the namespace.

**Guidelines: no namespace** You must remove all of the namespace’s volumes before you can remove the namespace with `no namespace`. Removing a volume is a complex process, described in the documentation for the [volume](#) command. The [remove namespace](#) command removes all volumes for you; best practices dictate that you use that command instead. The [remove service](#) command removes the namespace and all other configuration objects that are exclusively dedicated to the namespace, such as external filers and global servers.

**Samples** `bstnA(gbl)# namespace ns`  
This will create a new namespace.

```
Create namespace 'ns'? [yes/no] yes
bstnA(gbl-ns[ns])#
 creates a namespace called “ns.”
```

```
bstnA(gbl)# no namespace myNameSpace
 deletes the “myNameSpace” namespace.
```

**Related Commands** [volume](#)  
[protocol](#)  
[enable \(gbl-ns, gbl-ns-vol\)](#)  
[volume-group](#)  
[show namespace](#)  
[show global-config namespace](#)  
[remove namespace](#)  
[remove service](#)

## ntlm-auth-db (gbl-ns)

**Purpose** *This command is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI command.*

Use the `ntlm-auth-db` command to assign an NTLM-authentication database to the current namespace.

Use the `no` form of the command to remove an NTLM authentication database.

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ntlm-auth-db name`  
`no ntlm-auth-db name`

*name* (1-64 characters) is the name of an NTLM authentication database. Use the [show ntlm-auth-db](#) command for a list of configured NTLM databases.

**Default(s)** None

**Guidelines** This feature is designed for demonstrations with limited CIFS-service offerings. This is for CIFS services that either do not support Kerberos or support Kerberos with unconstrained delegation. For a namespace behind a non-Kerberos service, or a service with unconstrained delegation, the [ntlm-auth-server](#) is designed for long-term use.

Use this command only under the guidance of F5 personnel.

This command assigns an NTLM authentication database to a namespace. One database can be used in multiple namespaces. Use the `gbl-mode ntlm-auth-db` command to create an NTLM authentication demo database.

You must also use [cifs authentication ntlm](#) and/or [cifs authentication ntlmv2](#) for the namespace to support NTLM or NTLMv2 authentication.

If a single front-end [cifs](#) service has exports from more than one namespace, this group of NTLM-Authentication DBs must be the same for all of the exported namespaces. (The [export \(gbl-cifs\)](#) command exports a namespace volume through CIFS.) If this command makes the current namespace inconsistent with the other namespace(s) behind the same CIFS service, the CLI prompts with an opportunity to make the same change in the other namespace(s). Enter **yes** to allow the CLI to propagate the change to the other namespace(s).

Use the [show ntlm-auth-db](#) command to display a list of configured NTLM authentication databases.

**Sample** `bstnA(gbl-ns[ns1])# ntlm-auth-db DEMO`  
assigns the NTLM authentication database, “DEMO,” to the current namespace.

**Related Commands** [namespace](#)  
[cifs authentication](#)  
[ntlm-auth-db](#)  
[show ntlm-auth-db](#)

---

## ntlm-auth-server (gbl-ns)

**Purpose** *This command is only necessary behind a [cifs](#) service that uses unconstrained delegation (or is not joined to its domain). Best practices dictate that you use constrained delegation, as described in the [domain-join](#) documentation, and avoid this CLI command.*

Use the `ntlm-auth-server` command to assign an ARX Secure Agent (ASA) server to the current namespace. To support clients from multiple Windows domains, you can use this command multiple times.

Use the `no` form of the command to remove an ASA from the namespace. This prevents clients in the ASA's Windows Domain from using NTLM or NTLMv2 authentication.

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ntlm-auth-server name`  
`no ntlm-auth-server name`

*name* (1-128 characters) is the name of an ASA.

**Default(s)** None

**Guidelines** Use this command to assign an ARX Secure Agent (ASA) server to a namespace. The ASA facilitates NTLM and/or NTLMv2 authentication for the namespace's clients. Each ASA runs on a Windows-Domain Controller (DC) for a single Windows Domain. See the *ARX Secure Agent Installation Guide* for more information.

After you install the ASA on a DC, use the [ntlm-auth-server](#) command to configure it on the ARX. Then use this command to make it available to the current namespace. Use the [show ntlm-auth-server](#) command to display the configured ASAs along with connection statistics.

### ◆ Note

*If the namespace's front-end CIFS Service uses **constrained delegation**, introduced with Windows Server 2003, the Secure Agent (and this command) is unnecessary. An administrator with "Domain Administrator" privileges can go to the DC and configure constrained delegation for this CIFS service. You can use the [probe delegate-to](#) command to find all back-end filers behind a CIFS service, which the DC administrator adds to the CIFS service's "delegate-to" list. Once the CIFS service is set up this way at the DC, the service's NTLM/NTLMv2 clients can authenticate without help from a Secure Agent.*

**Guidelines: Multi-Domain Support and Redundant ASAs** A single namespace can support NTLM/NTLMv2 for clients from multiple Windows domains. For each supported domain, install an ASA on at least one DC. Additionally, you can assign multiple ASAs from the same domain to a namespace, for redundant coverage. If the namespace has two or more ASAs for the same domain, it selects the ASA running the highest version of software.

**Guidelines: Co-Existence with Kerberos** A namespace can authenticate its clients with NTLM, NTLMv2, and Kerberos concurrently. This facilitates network transitions from NTLM to Kerberos. Use [cifs authentication](#) to configure NTLM, NTLMv2, Kerberos, or any combination of those authentication protocols. Each client chooses a protocol from that set.

**Guidelines: Same Set of ASAs for All Namespaces Behind a CIFS Service** If a single front-end [cifs](#) service has exports from more than one namespace, this group of ASAs must be the same for all of the exported namespaces. (The [export \(gbl-cifs\)](#) command exports a namespace volume through CIFS.)  
If this command makes the current namespace inconsistent with the other namespace(s) behind the same CIFS service, the CLI prompts with an opportunity to make the same change in the other namespace(s). Enter **yes** to allow the CLI to propagate the change to the other namespace(s).

**Guidelines: Removing an ASA** Removing an ASA (with no `ntlm-auth-server`) may stop NTLM and NTLMv2 support for the ASA's Windows domain; if this is the only ASA for the domain, clients from that domain can no longer authenticate through NTLM. This may also affect Kerberos clients in the domain if they drop down to NTLMv2 or NTLM. You can add a new ASA to the namespace at any time to support NTLM and/or NTLMv2 in a new Windows domain.  
This is not an issue if the [cifs](#) services in from of the namespace all support constrained delegation. You can use [show cifs-service all](#) to see all CIFS services, the namespace behind each service, and whether or not the service supports constrained delegation.

**Guidelines: An Alternative NTLM-Authentication Option** For demonstration purposes, there is an alternative to configuring an external ASA: you can use [ntlm-auth-db](#) to map a small group of clients to a single set of valid NTLM credentials. The switch uses the back-end credentials to authenticate to CIFS filers.

**Sample**

```
bstnA(gbl-ns[insur])# ntlm-auth-server server1
```

NFS and CIFS services may export volume paths from multiple namespaces subject to certain restrictions. Parameter 'NTLM auth servers' for namespace 'insur' conflicts with that for namespace 'medarcv' in service 'ac1.medarch.org'. Synchronize conflicting parameter(s) for all the namespaces exported along with this namespace in a service and continue? [yes/no] **yes**  
assigns the ASA, "server1," to the current namespace.

**Related Commands** [namespace](#)  
[show ntlm-auth-server](#)  
[cifs authentication](#)  
[ntlm-auth-server](#)

---

# protocol

**Purpose** Use the `protocol` command to establish the protocol for accessing the files in this namespace (NFSv2UDP, NFSv3UDP, CIFS, or NFSv3TCP).

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `protocol {nfs2 | nfs3 | cifs | nfs3tcp}`  
`no protocol {nfs2 | nfs3 | cifs | nfs3tcp}`

`nfs2 | nfs3 | cifs | nfs3tcp` is a required choice:

`nfs2` is NFS version 2 over UDP,

`nfs3` is NFS version 3 over UDP,

`cifs` is CIFS, and

`nfs3tcp` is NFS version 3 over TCP.

**Default(s)** None

**Guidelines** You can repeat this command to configure multiple protocols for the namespace. All of the namespace's shares must support all of the file-access protocols you set for the namespace. For example, if you set `nfs2` for the namespace, all of the shares in this namespace must support NFSv2.

After the first share is imported, the CLI only allows protocol changes that do not affect client service. Any of the following changes interrupt service:

- converting a single-protocol namespace to a multi-protocol namespace,
- removing CIFS,
- removing NFS2, or
- removing both of NFS3 and NFS3/TCP.

To make any of the above changes after the volume is imported, you must use `nsck ... destage`, change the protocol with this command, then bring the volume back online with `enable (gbl-ns, gbl-ns-vol)`.

For other protocol changes, such as adding NFSv2 to a running NFSv3 namespace, you must disable the volume (no `enable (gbl-ns, gbl-ns-vol)`) and its front-end service (no `enable (gbl-cifs, gbl-nfs)`), change the protocol, then re-enable both. This causes a shorter service outage.

A namespace cannot support both `nfs2` and `nfs3tcp` unless it also supports `nfs3`.

**Samples** `bstnA(gbl-ns[ns])# protocol nfs2`  
 sets the current namespace to support NFSv2 UDP.

`bstnA(gbl-ns[ns1])# protocol cifs`  
 sets the current namespace to support CIFS shares.

**Related Commands** [namespace](#)

## proxy-user (gbl-ns)

**Purpose** Use this command to assign Windows credentials (username, password, and Windows domain) to the current namespace. The namespace's managed volumes use these credentials to import CIFS shares, periodically check their health, and migrate files between them.

Use the **no** form of the command to remove a proxy-user configuration from this namespace.

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **proxy-user** *name*  
**no proxy-user**

*name* (1-32 characters) is the Windows proxy user to associate with the current namespace.

**Default(s)** None

**Guidelines** From gbl mode, use the [proxy-user](#) command to add a proxy-user configuration to the ARX.

If the proxy user has an FQDN for its [windows-domain \(gbl-proxy-user\)](#), it uses Kerberos to authenticate with back-end filers. If it fails to get a Kerberos ticket, it drops down to NTLMv2, and then (if that fails, too) NTLM.

Use the [show proxy-user](#) command to view all configured proxy-users and their associated usernames and Windows domains.

---

◆ **Note**

*This has no relationship to the [proxy-user \(gbl-filer\)](#) command, which a snapshot-supporting volume uses to log into the filer's CLI. This command supports CIFS imports and policy migrations, and the [gbl-filer](#) command supports coordinated snapshots. You must assign both types of proxy users to support both features.*

**Sample** `bstnA(gbl-ns[medarcv])# proxy-user acoProxy2`  
associates proxy user "acoProxy2" with the current namespace.

**Related Commands** [proxy-user](#)  
[show global-config namespace](#)  
[show proxy-user](#)

---

## remove namespace

**Purpose** Use the `remove namespace` command to remove a namespace or volume, along with all of its associated metadata and front-end exports.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `remove namespace name [volume volume] [timeout seconds] [sync]`

*name* (1-30 characters) identifies the namespace.

*volume* (optional, 1-1024 characters) focuses on a single volume.

*seconds* (optional, 300-10,000) sets a time limit for the removal of each namespace (or volume) component.

**sync** (optional) shows the operation's progress at the command line. With this option, the CLI prompt does not return until all components have been removed.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before removing any configuration objects or metadata; enter **yes** to proceed.

This removes the following objects from a namespace or volume:

- all policy (rules, share farms, and filesets)
- all shares and metadata shares
- all front-end exports that reference the volume(s)
- all metadata behind the volume(s)

By default, this command generates a report to show all of the actions it takes to remove the volume(s), in order. The CLI shows the report name after you issue the command, and then returns. You can enter CLI commands as the namespace software removes the objects in the background. Use [tail](#) to follow the report as it is written. Use [show reports file-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the [copy](#) or [delete](#) commands. Use the **sync** option to send the status to the command line instead; the command does not generate a report if you use the **sync** option.

To remove a namespace and all other configuration objects dedicated to the namespace (including global servers and external filers), use [remove service](#). To remove a share from a volume, use [remove-share migrate](#) or [remove-share nomigrate](#). Use the [remove namespace ... policy-only](#) command to remove all policy objects (rules, share farms, and/or filesets) from a namespace or volume. The [remove namespace ... volume ... exports-only](#) command finds all front-end exports for a volume and removes them, leaving the volume itself intact.

**Sample** prtlnDA# `remove namespace insur_bkup sync`

```
Remove namespace 'insur_bkup'? [yes/no] yes
% INFO: Removing service configuration for namespace insur_bkup
% INFO: Removing CIFS browsing for namespace insur_bkup
% INFO: Removing volume policies for namespace insur_bkup
% INFO: destroy policy insur_bkup /insurShdw
% INFO: Removing shares for namespace insur_bkup
% INFO: no share backInsur
% INFO: Removing volume metadata shares for namespace insur_bkup
% INFO: no metadata share nas-p1 path /vol/vol1/mdata_B
% INFO: Removing volumes for namespace insur_bkup
% INFO: Removing NFS services for namespace insur_bkup
% INFO: Removing CIFS services for namespace insur_bkup
% INFO: no volume /insurShdw
% INFO: Removing namespace metadata shares for namespace insur_bkup
% INFO: Removing namespace insur_bkup
% INFO: no namespace insur_bkup
```

removes the “insur\_bkup” namespace, showing progress on the command line instead of in a report.

**Related Commands** [remove service](#)  
[remove-share migrate](#)  
[remove-share nomigrate](#)  
[remove namespace ... policy-only](#)  
[remove namespace ... volume ... exports-only](#)  
[wait-for remove](#)

---

## sam-reference

**Purpose** A properly-empowered CIFS client can edit the list of users and groups who are permitted to access a file. For example, the owner of a file can allow read-access for a trusted group. A Windows server keeps a list of all available groups in its Security Account Management (SAM) database; a namespace proxies all of its SAM requests to one of the CIFS servers behind it. For installations that use Local Groups on some filers, it is possible for the switch to choose a filer that is unaware of all groups in the namespace. You can use the `sam-reference` command to choose the filer manually. This command is unnecessary unless at least one of the filers uses Local Groups.

Use `no sam-reference` to allow the namespace to choose the SAM-reference filer. This is appropriate to an installation that only uses globally-defined groups.

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `sam-reference ext-filer [cluster cluster-name]`  
`no sam-reference`

*ext-filer* (1-64 characters) identifies the external filer to use. For a list of configured external filers, use [show external-filer](#).

*cluster-name* (optional, 1-64 characters) is only relevant if the ARX is part of a disaster-recovery (DR) configuration. In a DR configuration, there is an active ARX cluster with one set of filers and a backup cluster with a mirrored set of filers. This determines which cluster uses this *ext-filer* for its SAM queries. Run the `sam-reference` command twice per namespace if you use DR: once to designate the SAM-reference filer for the active cluster, and again to determine the SAM-reference filer at the backup cluster. Use [show cluster](#) for a list of configured clusters. If you omit this option, the command assumes that this is the local cluster.

**Default(s)** The switch chooses one of the namespace's filers as a SAM reference.

**Guidelines** This command does not apply to an NFS-only namespace. This only affects CIFS clients who want to add group access to one of their files. The namespace must query a SAM database on a back-end filer to offer the list of available groups and users.

Each CIFS filer has its own SAM database, with its own names for groups and users. The namespace chooses one filer for all of its SAM queries. For installations that use Global Groups, this is not an issue. For installations that use Local Groups at one or more filers, it is possible for the namespace to choose a filer that does not support all possible groups.

---

### ◆ Note

*SAM-database queries are not associated in any way with the file (per the standard CIFS and SAM protocols), so the client does not provide the information to determine which CIFS filer should respond to each query. The namespace therefore chooses one CIFS filer for all SAM queries.*

**Guidelines (Cont.)** For installations where Local Groups differ amongst the CIFS filers, one of the filers must define all of the groups for the namespace. If necessary, you may need to define some Local Groups at one of the back-end filers to create a superset. Use this command to identify that filer.

Conversely, this command is not needed if every filer behind the namespace supports the same set of local groups. This is a recommended configuration.

If a single front-end [cifs](#) service has exports from more than one namespace, this SAM-reference filer must be the same for all of the exported namespaces. By extension, the single SAM-reference filer must define all the Local Groups behind all of the namespaces behind the CIFS service. (The [export \(gbl-cifs\)](#) command exports a namespace volume through CIFS.)

The currently chosen SAM-reference filer (if any) appears in the output of the [show global-config namespace](#) command.

**Samples** `bstnA(gbl-ns[medarcv])# sam-reference fs2`  
establishes “fs2” as the SAM-reference filer for the “medarcv” namespace.

`bstnA(gbl-ns[medarcv])# no sam-reference`  
allows the namespace to choose any CIFS filer behind the namespace as its SAM reference.

**Related Commands** [namespace](#)  
[show sid-translation](#)  
[show global-config namespace](#)  
[show cluster](#)

---

# show namespace

**Purpose** Use the `show namespace` command to show summaries of all namespaces, or to include a single namespace name to view configuration details for that namespace.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show namespace`  
`show namespace name [volume vol-path [share share-name]]`  
`show namespace all`

*name* (optional, 1-30 characters) identifies the namespace. If you omit this, the output lists all namespaces on the switch.

*vol-path* (optional, 1-1024 characters) is the name of the volume.

*share-name* (optional, 1-64 characters) is the name of the share.

`all` lists details for all configured namespaces.

**Guidelines** This shows the full configuration and status of a namespace. For status only (to monitor the progress of an import), you can use the smaller [show namespace status](#) command.

The `show namespace` output displays the following fields:

Description is set with the [description \(gbl-ns, gbl-ns-...\)](#) command.

Metadata Cache Size is the internal cache size in MB (512 MB is the default). To change the cache size, use the [metadata cache-size](#) command.

Proxy User is the username/password used by the ARX to access back-end CIFS shares. Use the [proxy-user \(gbl-ns\)](#) command to set this.

Filer SMB Signatures describes this namespace's setting for SMB signing, a CIFS security feature. This is **Enabled** (use SMB signing if and only if the filer requires it), **Required** (only connect to CIFS filers that agree to use SMB signing), or **Not Enabled** (only connect to filers that do *not* require SMB signing). You can change this with the [cifs filer-signatures](#) command.

NFS Character Encoding only appears in a namespace that supports NFS. This shows the character encoding used for all file and directory names sent to NFS clients. You can change this with the [character-encoding nfs](#) command.

SAM Reference Filer only appears if explicitly set with the [sam-reference](#) command. This shows the CIFS filer used to answer all CIFS-client queries to the Security Account Management (SAM) database.

Supported Protocols lists the protocols (NFSv2, CIFS, and so on) supported by the namespace. This is set with the [protocol](#) command.

**Guidelines (Cont.)** CIFS Authentication appears only for a namespace that supports CIFS:

Protocols is a list of the authentication used (NTLM, NTLMv2, and/or Kerberos). Use [cifs authentication](#) to change this setting.

- **Anonymous Access (IPC\$ only)** may also appear in this list. This indicates that CIFS clients can access the namespace’s IPC\$ volume with the “anonymous” Windows-user account; some scanners/photocopiers require this access for saving files to the namespace’s CIFS volumes. You can use the [cifs anonymous-access](#) command to change this setting.
- **None** indicates that CIFS clients cannot authenticate to this namespace, and therefore cannot access any of the namespace’s storage.

**NTLM Servers** (only appears if configured) is a list of external authentications servers, set by [ntlm-auth-server \(gbl-ns\)](#).

**NTLM Database** (only appears if configured) is set by [ntlm-auth-db \(gbl-ns\)](#).

**Participating Switches** is a list of ARXes that support the namespace. For each switch, the volume groups are shown in parenthesis; this is where the namespace software runs. Before you enable a volume (not after), you can specify its volume group with the [volume-group](#) command.

**Guidelines: Metadata Shares (Namespace)** Metadata shares is shown only if the namespace uses a metadata-only share. Use the [metadata share](#) command to use a metadata-only share for the namespace. This is a table with the following columns (one row per configured share):

**Filer** is the IP address or DNS name for the filer,

**Backend Path** is the filer’s share name or NFS-export path,

**Contains Metadata** is “yes” for the one export that holds metadata, and

**Status** is the current status of the share. For possible status values, see *Guidelines: Import Status* below.

**Guidelines: Windows Management Authorization** Windows Management Authorization Policies appears for namespaces that support CIFS and management by authorized Windows clients. The Microsoft Management Console (MMC) bundled with Windows is a typical interface for remote management. The [windows-mgmt-auth \(gbl-ns\)](#) command assigns a group of authorized clients to a namespace. If any Windows-management-authorization (WMA) groups are assigned to the namespace, they are listed in this table.

---

**Guidelines: Volumes** Volumes is a list of managed volumes in the namespace. Use the [volume](#) command to create a volume.

CIFS: is a list of supported CIFS options, if applicable. The following commands set these options: [compressed-files](#), [named-streams](#), [persistent-acls](#), [sparse-files](#), [unicode-on-disk](#), [cifs case-sensitive](#), and [cifs file-system-name](#).

Volume [freespace](#) is the amount of free space advertised to this volume's clients. After the free-space amount is the calculation method for free space: "automatic," or "manual," or "clients use dir-master-only."

- [automatic](#) - Add up the free space from all shares behind the volume and present the sum to all clients. The namespace volume monitors the back-end-storage ID behind each share; if two or more shares have matching storage IDs (that is, they draw their free space from the same storage pool), only one of the shares has its free space counted. This is the default setting for a new volume.
- [manual](#) - Add up the free space from all shares, ignoring any shares that draw from the same back-end-storage pool. You can manually eliminate shares from this sum with [freespace ignore](#). You can also adjust the free space that is counted for each share with [freespace adjust](#). Use [freespace calculation manual](#) to set this.
- [clients use dir-master-only](#) - Give the client the free space for the *master* back-end share only, without adding any any free space from any of the *stripe* shares in the same volume. The volume chooses the master share when the client connects to the volume through a front-end share or subshare: the volume starts with the root directory of that front-end share, finds the master instance of that directory, and chooses the back-end share that hosts that master directory. This is useful for volumes where directory trees reside only on a single back-end filer most of the time. Use the [freespace calculation dir-master-only](#) command to set this.

Volume [total space](#) is the sum of total space on all shares behind the volume. This is the actual space. The volume's clients may see different space settings, as determined by the settings above.

CIFS [quotas](#) is [Enabled](#) if the volume supports path-based quotas on its back-end filers. This indicates that the volume shows free-space values based on these back-end quotas; each client sees his or her space quota, not the entire size of the volume. You can use the [freespace cifs-quota](#) command to enable or disable this feature.

Auto Sync Files: [Enabled](#) appears only if the volume is permitted to synchronize metadata that is found to be incorrect. This means that certain client-access errors will trigger an auto-sync operation. Use the [auto sync files](#) command to enable or disable this feature.

**Guidelines: Volumes  
(Cont.)**

**Auto Sync Options: Rename-Files** appears only if the volume is permitted to rename files when auto-synchronizing. That is, if auto-sync discovers a file whose name is the same as an already-imported file, this feature allows the volume to rename the newly-discovered file. As above, use the [auto sync files](#) command to enable or disable this feature.

**Metadata size** is the amount of metadata space allotted to this volume.

**Metadata free space** is the amount of free space left on this volume's metadata share. This does not appear if metadata is stored on the internal disks.

**Filer Subshares: Enabled** appears only if the [filer-subshares](#) flag is enabled. This applies only to managed volumes that support CIFS; it indicates that the volume can pass a client from a CIFS subshare at the front-end service through to the corresponding subshare at the back-end filer. This pass-through mechanism makes it possible to support share-level ACLs for the volume's subshares. The additional text, **native-names-only**, appears if the [filer-subshares](#) command was invoked with a flag of the same name.

**Oplock support** appears only for volumes that support CIFS. This shows whether or not this volume supports CIFS opportunistic locks (oplocks). This can be Enabled, Disabled, or Automatic, as set by the [cifs oplocks-disable](#) command.

**Notify-change mode** shows the degree of support for the CIFS *change notification* feature. This is "Normal" (tell clients only of changes in the top level of the directory requested, ignoring any request to track changes in its subtree), "Use Subtree Flag" (inform CIFS clients of all back-end file system changes that they request), or "No changes sent" (silently ignore all client requests for change notification). You can change this with [cifs notify-change-mode](#).

**CIFS path cache** only appears for volumes that support CIFS. This is "Enabled" or "Not Enabled," depending on the [cifs path-cache](#) setting. If enabled, NSM processors keep a cache of the volume's CIFS paths as it learns them. This prevents repetitive queries to the volume process on an ACM processor. Otherwise, NSM processors query the volume process for each CIFS-client request.

**CIFS access based enum** also appears only for volumes that support CIFS. This is "Enabled" or "Not Enabled," possibly followed by some combination of "Auto-Enable," "Ignore Metadata Skew," and/or "Full Autosync." This output depends on the [cifs access-based-enum](#) setting. If enabled, the volume changes its behavior for sending directory listings to its CIFS clients; if a back-end share omits some files or directories, the volume assumes that the omissions are caused by ABE, and makes no attempt at correction. Additionally, the volume only allows a share to import if the share has ABE enabled at its back-end filer; the volume rejects shares with ABE disabled, or automatically enables ABE if the "Auto-enable" flag is raised. If "Not Enabled," the volume presumes that none of its filers have ABE enabled, and therefore may amend a directory listing with omissions.

**Snapshots** is either "Enabled" or "Not Enabled," depending on whether or not the volume contains at least one [snapshot rule](#).

**Migration method: Direct** is either "Staged" or "Direct." This indicates the method for migrating files; either performing a network transfer to a staging area first, or performing the transfer directly to the final location. The direct method fails if the migration is interrupted by a snapshot. You can use the [policy migrate-method](#) command to change this setting.

---

**State** is usually Enabled or Disabled, as set by the [enable \(gbl-ns, gbl-ns-vol\)](#) command. This cycles through several stages during import. The namespace *imports* the files and directories from back-end storage when you create and enable the volume and its share(s). See *Guidelines: Volume State*, below, for an explanation of all possible volume states.

**Host Switch** is the ARX with the [volume-group](#) where this volume resides. This is typically the ARX peer where the volume was originally created. If you want to use [show volume-group](#) to show this volume's group, run the command on the ARX shown in this field.

**Instance** is an integer ID for the volume processes.

**Volume Group** is the volume group where this volume's processes run. Several volumes from the same namespace can run in a given volume group. The volume group is automatically assigned when the volume is enabled. You can optionally use the [volume-group](#) command to pre-set the volume group beforehand.

**Processor** shows the physical CPU where the volume group is currently running. A volume group can fail over between peers in a redundant pair. The processor appears in *slot.processor* format.

**Files** is the number of files in the volume, and the file credits that are remaining for the volume. This also shows the maximum possible number of file credits if [auto reserve files](#) is set. The auto-reserve feature adds file credits as the volume grows.

The volume's metadata shares appear next.

**Guidelines: Metadata Shares (Volume)**

Metadata shares is shown only if the volume uses a metadata-only share. Use the [metadata share](#) command to use a metadata-only share for the volume. This is a table with the same columns as shown above in *Guidelines: Metadata Shares (Namespace)*.

**Guidelines: Shares**

Share name (s) are the configured shares in the volume. Use the [share](#) command to add a share to the volume.

◆ **Note**

---

*Instead of using `show namespace` for this information, you can use the shorter [show namespace status](#) or [show share status](#) command to display share, filer, path, and import status only.*

**Guidelines: Shares  
(Cont.)**

If the share has been designated as a [replica-snap](#) share, a replica of one of the other shares that is dedicated to snapshots, `[replica-snap]` appears next to the share name. Many of the detailed fields (below) do not appear for replica-snap shares because they are irrelevant to snapshots.

**Description** appears only if someone set a [description \(gbl-ns, gbl-ns-...\)](#) for the share.

**Filer** is the filer that hosts the back-end share. This is set by the [filer](#) command. If `[Acopia Namespace]` appears after the filer name, the filer is a [managed-volume](#) in a [direct](#) volume; this shows the namespace name and the **Volume Path** field (below) shows the volume name.

**Volume Path** only appears for [managed-volume](#) shares in [direct](#) volumes. This is the name of the volume behind this direct share, as set by the [managed-volume](#) command.

**NFS Export** is the name of the NFS export at the back-end filer. This is also set by the [filer](#) command.

**CIFS Share** (also set by [filer](#)) is the name of the CIFS share at the filer. In a multi-protocol namespace, both the **NFS Export** and **CIFS Share** appear for each namespace share.

**Features** is a list of multi-protocol features supported at the back-end share:

- "cifs-acls,"
- "unix-perm,"
- "shared-attr,"
- "asymmetric-ro,"
- "no-trail-period" (the filer creates a CIFS FGN for file/directory names that end in a period, so the volume will never migrate any such names to it),
- "fgn-see-thru" (the filer allows write access to files through their CIFS "8.3" names, so the share is not supported in a multi-protocol volume),
- "ignore-unix" (the share is backed by an NTFS qtree that ignores changes to Unix permissions without any error; the managed volume also quietly drops these changes),
- "cifs-case-blind," and/or
- "unix-acls" (The filer is a NetApp with the `cifs.perserve_unix_security` option enabled. The NetApp converts Unix security flags into a special CIFS ACL, so that CIFS clients can change the Unix security settings. The volume software records this setting at import time so that it can support those CIFS clients.)

---

**Guidelines: Shares  
(Cont.)**

**CIFS Maximum Request Size** is the maximum size (in bytes) for a CIFS request (other than a write request). This is a maximum found at the back-end filer. This information is for internal use only.

**CIFS Access-based Enum** is “Exclude” if someone issued `cifs access-based-enum exclude` for the share. Otherwise, this field does not appear in the output. The “Exclude” flag indicates that the filer behind the share cannot support access-based enumeration (ABE), so this share is excluded from the volume’s ABE-consistency checking.

**SID Translation** only appears for a CIFS volume that translates Security IDs (SIDs) for all files migrated to or from this share. This indicates that the filer uses Local Group support, so the SID for each group name is unique at this filer. Use the `sid-translation` command to enable SID translation for a share.

**Ignore SID errors** only appears for a volume that supports CIFS. A “Yes” indicates that the back-end server is configured to return an error for a file or directory with an unknown SID, but accept the file/directory anyway. A “No” indicates that SID errors from the filer indicate a rejection of the file or directory. You can change this with the `ignore-sid-errors` command.

**Status** is the current status of the share. This cycles through several stages during import. The namespace *imports* the files and directories from back-end storage when you create and **enable** the share. See *Guidelines: Share-Import Status*, below.

**Volume Root Backing** appears if the share is designated to hold new files created in the root of the volume. This is the first share imported into the volume, which is typically the first share configured.

**Critical Share** appears if the share has been tagged with the `critical` command. If a redundant switch loses contact with a critical share, it may fail over to its peer switch.

**Migrate Retain Files: Yes** only appears the share is set to keep copies of all files migrated away from it. The copies are kept in a hidden directory at the root of the share. Use `migrate retain-files` to edit this setting.

**Strict Attr Consistency: No** only appears if you disable strict-attribute consistency. This is recommended for multi-protocol (CIFS and NFS) shares, which may have directories with different CIFS-side and NFS-side names. If the volume cannot find the CIFS-side name of a directory, it may not be able to find all of its CIFS attributes. The volume must either rename these directories (see below) or be allowed to operate without strict-attribute consistency; it cannot import the share otherwise. You can use `no strict-attribute-consistency` to set this.

**Import Sync Attributes: Yes** only appears if (during import) the volume is allowed to synchronize the attributes of colliding directories in this share. That is, if a directory in this share has the same name as an already-imported directory but different file attributes (such as read/write permissions), the volume can change the attributes. This is strongly recommended for shares in multi-protocol namespaces. Use `import sync-attributes` to change this.

**Import Rename Files: No** only appears if (during import) the volume is prevented from renaming collision files in this share. A file is said to *collide* if it has the same name and path as an already-imported file or directory. Use `modify` to allow the volume to change files at all during import, and use `no import rename-files` to disallow file-name changes in this particular share.

**Guidelines: Shares  
(Cont.)**

**Import Skip Managed Check: Yes** is another import option. This only appears if someone used [import skip-managed-check](#) on this share. It means that the volume will not run a time-consuming test on any of the share's directories during import. The test confirms that the directory is not already managed by another ARX volume.

**Import Rename Directories: No** only appears if (during import) the volume is prevented from renaming collision directories in this share. Use [modify](#) to allow the volume to change directories at all during import, and use [no import rename-directories](#) to disallow directory-name changes in this particular share.

**Import Rename Non Mappable Directories: Yes** only appears if the volume is allowed to rename a multi-protocol directory with a CIFS-side name that is unmappable to the NFS character-encoding. Filers create unintelligible NFS-side names for these files; this indicates that the volume is allowed to rename these directories during import. Use [import rename-directories unmapped-unicode](#) to set this.

**Import Priority** shows the priority for this share over other shares in the same volume. If two shares have a conflicting file or directory and their import priorities are different, the share with the higher priority wins the conflict. The file or directory on the winning share is the *master*, and the other file or directory may have to change according to one of the import settings above. You can use the [import priority](#) command to change the import priority for any given share.

**Free space on storage** is the remaining space on the share. The expression, "(excluded from volume)," appears after the number if someone used the [freespace ignore](#) command in this share; it means that this share's free space is not being counted toward the volume's free space.

**Freespace adjustment** only appears if someone used [freespace adjust](#) to change the advertised free space for this share. This is the adjustment to the free space advertised for this back-end share. For example, if this is 1024 bytes, the volume adds 1024 bytes to the share's current free space.

**Total space on storage** is the sum of the share's free space (above) and used space.

**Apparent size of storage** is the size of the share that is advertised to clients. You can change this with the [freespace apparent-size](#) command; this field only appears if that command is set.

**Policy Maintain Freespace** is the amount of free space to maintain on the share. The policy engine does not migrate files to this share if it drops below this amount of free space. You can change this with the [policy freespace \(gbl-ns, gbl-ns-vol\)](#) command.

**Policy Resume Freespace** is another free-space threshold for this share. If the share drops below the free-space to maintain (above), the share is ineligible for any more migrations until it rises back up to this *resume* value. You can change this threshold with the same [policy freespace \(gbl-ns, gbl-ns-vol\)](#) command that you use for the *maintain* threshold.

**Free files on storage (NFS shares only)** is the maximum number of files that can be added to the back-end export. All file systems impose a limit on the maximum number of files on a share.

**Virtual inodes (NFS direct shares only)** is the total number of inodes (files) that can be supported at the direct share.

**Guidelines: Shares  
(Cont.)**

**Transitions** shows the number of times that the share has changed from offline to online, or from online to offline.

**Last Transition** is the date of the last transition.

**Last Probe Status** only appears if the most-recent probe of the share resulted in a failure. The volume probes the share at regular intervals to confirm its health; if this field appears, the share failed the latest probe and the failure status appears here. This often indicates a problem with the back-end filer or filer connection; contact F5 Support if you see this field and require any guidance.

**Guidelines: Volume  
State**

In the Volume's **State** field, any of the following messages may appear:

- **Enabled** - Someone used [enable \(gbl-ns, gbl-ns-vol\)](#) to enable the volume. If nothing appears after this, the volume is capable of processing client requests. Otherwise, one of the following messages appears in parenthesis, indicating an interim and/or degraded state:
  - **Waiting for available metadata location** - The volume is looking for an available share amongst its configured metadata shares ([metadata share](#)).
  - **Metadata free space low,**
  - **Metadata free space very low, and**
  - **Insufficient metadata free space** all indicate a progressively-worse problem with free space on the volume's metadata share: the free space is below 512 M, 256 M, or 128 M. Each volume requires multiple Gigabytes of space for its metadata. Choose another metadata share for the volume (using [nsck ... migrate-metadata](#)), or connect to the metadata share and clear any space outside of any .acopia directories.
  - **Metadata filer failed** - The volume's metadata share is offline. The volume cannot function without this share. Check and correct the share at the file server itself. If necessary, use [nsck ... migrate-metadata](#) to move the volume's metadata to a new share.
  - **Metadata starting** - Volume processing is starting (perhaps after an ARX reboot), and the volume is re-connecting to its metadata share.
  - **No enabled shares** - The volume is ready for processing, but none of its shares are running. Use [enable \(gbl-ns-vol-shr\)](#) to enable a share.
  - **Read Only** - The volume allows reads but no writes. This might be because it is configured as a [shadow](#) volume, or because no one has set the [modify](#) flag.
  - **Instance not responding** - Volume processing has failed.
- **Starting** - The volume's enabled shares are currently importing files and directories from back-end filers.
- **Stopping** - Someone has issued a [no enable \(gbl-ns, gbl-ns-vol\)](#) command to stop processing in this volume, and the volume is in the process of stopping. You cannot change the volume's configuration until the volume reaches the **Disabled** state.

**Guidelines: Volume State (Cont.)**

- **Disabled** - The volume is fully stopped after someone has issued a `no enable (gbl-ns, gbl-ns-vol)` command. Clients cannot access this volume. You can make changes to the volume's configuration.
- **Offline (Migrating Metadata)** - The volume's metadata is migrating from one filer to another. The volume comes back online after the migration finishes. You can use the `nsck ... migrate-metadata` command to migrate the volume's metadata.

**Guidelines: Share-Import Status**

In the Share's **Status** field, the following messages show the progress of a successful import:

- **Pending (Uninitialized)** - The share is configured, but either the volume or the share is not yet enabled. Use the `enable (gbl-ns, gbl-ns-vol)` command to enable the volume. For a new share in an already-enabled volume, use the `enable (gbl-ns-vol-shr)` command to enable the share.
- **Pending Import** - Scheduled for import. If this volume supports CIFS and has `filer-subshares` or `cifs access-based-enum` enabled, the volume is synchronizing all of the subshares and/or ABE settings it can find on the filers behind it.
- **Pending Import: Unavailable** - The volume lost contact with the filer after the share was scheduled for import. You can use `no enable (gbl-ns-vol-shr)` on this share to send it to the **Offline: Disabled** status; this allows an `nsck ... rebuild` of the volume.
- **Importing: a items scanned, b items imported** - Actively inventorying the back-end storage. Both counters, *a* and *b*, are the sum of files and directories.
- **Import Interrupted** - The ARX unexpectedly lost contact with the back-end share/export, disrupting the import process.
- **Import Paused: Volume Disabled** - Someone issued the `no enable` command while the volume was importing. To restart the import, use the `enable (gbl-ns, gbl-ns-vol)` command.
- **Pending Online** - The share is nearly online.
- **Online: Direct** - This volume has `direct` shares, and is ready for client access (no import is required).
- **Online** - Import completed successfully, back-end storage is ready to be used.

---

**Guidelines:  
Disable/Removal  
Status**

These messages indicate the status of a share that has been disabled and/or removed:

- **Offline: Disabled** - either the share or the entire volume is disabled. Use the [enable \(gbl-ns-vol-shr\)](#) command to enable the share; use the [enable \(gbl-ns, gbl-ns-vol\)](#) command to enable the entire volume.
- **Offline: Unavailable** - the volume lost contact with the filer.
- **Pending Remove** - The share has been marked for removal by the `no share` command. See [share](#).
- **Preparing Remove: n records visited** - The switch is scanning the volume's metadata, separating out the metadata for this particular share and retrieving all master-directory attributes from the back-end filer. The *n* is the number of files and directories scanned.
- **Removing: n records visited** - The switch is currently removing the share from the namespace. The *n* is the number of file/directory records that have been removed from the volume's metadata.
- **Remove Paused: Volume Disabled** - the volume was disabled after the removal started. Use the [enable \(gbl-ns, gbl-ns-vol\)](#) command to enable the volume and restart the share removal.
- **Remove Interrupted** - The ARX unexpectedly lost contact with the back-end share/export, disrupting the remove process.

**Guidelines: Import  
Errors**

An Error at the beginning of the message indicates the import failed. There are a large number of specific import errors, to help with diagnosis and recovery. See [Table 21.1 on page 21-49](#) for a full list of possible errors and suggestions for troubleshooting each error.

Once the error is corrected, you can use the `no share` command to remove the share, then `share` to re-import it. For metadata shares, the entire volume must be re-imported: use the [nsck ... rebuild](#) command for the volume.

- Samples** `bstnA# show namespace`  
lists all namespaces. See [Figure 21.1](#) for sample output.
- `bstnA# show namespace medarcv`  
shows all volumes in a CIFS namespace; see [Figure 21.2 on page 21-38](#).
- `bstnA# show namespace wwmed`  
shows all volumes in an NFS namespace; see [Figure 21.3 on page 21-43](#) for sample output.
- `prt1ndA# show namespace nemed volume /acctShdw`  
shows one volume with manual free-space calculations. See [Figure 21.4 on page 21-45](#) for sample output.
- `bstnA# show namespace insur volume /claims`  
shows one volume in a multi-protocol (NFS and CIFS) namespace. See [Figure 21.5 on page 21-46](#) for sample output.
- `bstnA# show namespace medco volume /vol share generic`  
shows one share in a direct volume. See [Figure 21.6 on page 21-48](#) for sample output.

| Error: A directory was removed from the filer during import.                         | <p>A directory was found during an early scan of the filer share, then later it was missing. Either a client or client application must have accessed the filer directly (that is, not through this managed volume) during the import.</p> <p>This ARX cannot support unexpected changes to the back-end shares during (or after) import.</p> <p>After you correct the problem, use <code>nsck ... rebuild volume</code> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error: A filename/directory could not be mapped to the namespace character encoding. | <p>One of the share's directories has a name with Unicode characters that are unsupported by the <code>character-encoding nfs</code> setting. CIFS file names are Unicode and can contain any character, but NFS servers and clients must each configure their character encoding for file names. The volume cannot import a directory with any un-mappable characters in its name.</p> <p>You can use the <code>import rename-directories unmapped-unicode</code> command to allow the volume to rename such directories during import, or you can rename them manually at the filer. Then restart the share import: enter <code>gbl-ns-vol-shr</code> mode and re use the <code>enable (gbl-ns-vol-shr)</code> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Error: a higher priority share failed to initialize import.                          | <p>A share with a higher <code>import priority</code> has failed its import, so this share cannot import. If any share import fails, the managed volume cannot import any shares with lower import priorities. Find the import error for the failed share(s), look for the error in this table, and take action as directed. This error is resolved as soon as all higher-priority shares successfully import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error: Access denied by filer.                                                       | <p>This indicates that the ARX does not have proper permissions to connect to the back-end filer, or to perform some operation in the filer share.</p> <p>For NFS exports, check your back-end filer configuration: the back-end share should allow <code>root</code> access to all of the ARX's proxy IP addresses. Use the <code>show exports</code> command examine all permission settings at the filer. Use the <code>show ip proxy-addresses</code> command to list all configured proxy IP addresses.</p> <p>For CIFS shares, the switch uses the namespace's <code>proxy user</code> (username and password). The proxy-user credentials must belong to the Administrators group at every filer behind the namespace. Use the <code>probe exports</code> command to check this. The <code>proxy-user (gbl-ns)</code> command sets the proxy user credentials for a namespace.</p> <p>This may also indicate that the ARX is examining a read-only directory, such as the “~snapshot” directory in a NetApp filer. Such directories should be ignored during import. The <code>gbl-filer ignore-name</code> command identifies these types of directories.</p> <p>After you find and fix the error, you can restart the share import: enter <code>gbl-ns-vol-shr</code> mode for this share and re use the <code>enable (gbl-ns-vol-shr)</code> command.</p> |

Table 21.1 Share Status Conditions

| Status Condition                                                     | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: Another share in the volume failed to import.                 | All shares in the volume must import successfully for the volume to come online. Address the share that does not have this error, then restart this share import: enter <code>gbl-ns-vol-shr</code> mode for this share and re use the <code>enable (gbl-ns-vol-shr)</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Error: Attempted to import subdirectory which is also a managed root | This share is a parent to an already-imported share. Namespace shares cannot overlap. Use the <code>filer</code> command to change the path or share name.<br><br>After you correct the problem, use <code>nsck ... rebuild volume</code> to reimport all shares in the volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Error: Attributes of the share root are inconsistent.                | The share's root directory has attributes (such as owner, group, and permission settings) that are inconsistent with those of the already-imported shares. You can access the back-end filer directly to change these attributes, or you can use the <code>import sync-attributes</code> command to allow the volume to change the attributes for you. Then re-enable the share ( <code>enable (gbl-ns-vol-shr)</code> ) to restart its import.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Error: Authentication error during import.                           | The ARX does not have proper permissions to connect to the back-end filer.<br><br>For NFS exports, check your back-end filer configuration: the back-end share should allow <code>root</code> access to all of the ARX's proxy IP addresses. Use the <code>show exports</code> command examine all permission settings at the filer. Use the <code>show ip proxy-addresses</code> command to list all configured proxy IP addresses.<br><br>For CIFS shares, the switch uses the namespace's <code>proxy user</code> (username and password). The proxy-user credentials must belong to the Administrators group at every filer behind the namespace. The <code>proxy-user (gbl-ns)</code> command sets the proxy user credentials for a namespace.<br><br>After you find and fix this issue, you can restart the share import: enter <code>gbl-ns-vol-shr</code> mode for this share and re use the <code>enable (gbl-ns-vol-shr)</code> command. |
| Error: Bad Export Path/Share Name                                    | The share cannot be found on the external filer. Use the <code>filer</code> command to change the path or share name for this share, then re-enable the share ( <code>enable (gbl-ns-vol-shr)</code> ) to retry the import.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                     | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: CIFS ABE check failed.                                        | <p>(CIFS) The volume supports <a href="#">cifs access-based-enum</a> (ABE), and attempted to replicate ABE settings between its back-end shares. This replication process failed. The same process also checks for CIFS subshares (<a href="#">filer-subshares</a>), so you can use <a href="#">sync subshares from-namespace ... tentative</a> to get a full report on this issue.</p> <p>This often occurs because the ARX does not have proper permissions to check for ABE support on this back-end share. The ARX uses the namespace's <i>proxy user</i> (username and password) as its identity when it checks for ABE support. The proxy-user credentials must belong to the Administrators group at this back-end filer. You can use the <a href="#">proxy-user (gbl-ns)</a> command to choose new proxy user credentials for the namespace.</p> <p>After you find and fix this issue, use <a href="#">nsck ... rebuild volume</a> to reimport all shares in the volume.</p> |
| Error: CIFS error during import scan.                                | <p>(CIFS) This is a CIFS error that is not an access or network error, but prevented the import. The syslog shows the specific error. Use <a href="#">show logs syslog</a> to read the syslog, or <a href="#">grep string logs syslog</a> to search for a specific string in the syslog.</p> <p>After you correct the error, re-enable the share (<a href="#">enable (gbl-ns-vol-shr)</a>) to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error: CIFS filer connection limit reached.                          | <p>(CIFS) The back-end filer imposes a limit on CIFS connections, and the import requires more connections than the filer allows. Correct this at the back-end filer and then re-enable the share to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Error: CIFS operation attempted on a symbolic link.                  | <p>(multi-protocol) The volume software encountered an NFS symbolic link on this back-end share, and the volume has <a href="#">cifs deny-symlinks</a> enabled. You can resolve this issue by using the <a href="#">no cifs deny-symlinks</a> command to allow the volume software to follow these links. Alternatively, you can remove all NFS symbolic links from the back-end share.</p> <p>After you fix this issue, use <a href="#">nsck ... rebuild volume</a> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Error: CIFS operation failed with an error during import.            | <p>(CIFS) The back-end filer returned an unexpected CIFS error during import. The syslog shows the specific error. Use <a href="#">show logs syslog</a> to read the syslog, or <a href="#">grep string logs syslog</a> to search for a specific string in the syslog. You may need to escalate to F5 Support.</p> <p>After you correct the error, re-enable the share (<a href="#">enable (gbl-ns-vol-shr)</a>) to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Error: CIFS operation failed with an error indicating a filer fault. | <p>(CIFS) The filer returned an unexpected error during the import, and the error indicates a problem at the filer itself. The syslog shows the specific error. (Use <a href="#">show logs syslog</a> to read the syslog, or <a href="#">grep string logs syslog</a> to search for a specific string in the syslog.) Check the filer itself and correct the problem there.</p> <p>After you correct the error, re-enable the share (<a href="#">enable (gbl-ns-vol-shr)</a>) to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                 | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Error: CIFS operation returned an error indicating an unsupported option.</p> | <p>(CIFS) The back-end share returned an error indicating that it does not support a CIFS option that the ARX requires. Consult the <i>F5 Data Solutions Compatibility Matrix</i> (included in this doc set) to confirm that the filer has been qualified for use behind the ARX. If the share cannot possibly support CIFS behind an ARX, you can use <code>no share</code> to remove the share from the volume.</p> <p>After you fix this issue, use <code>nsck ... rebuild volume</code> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                            |
| <p>Error: CIFS proxy-user not privileged.</p>                                    | <p>(CIFS) The namespace software attempted to write a test file to the share and failed. Go to the filer and check permissions for the namespace's <code>proxy-user (gbl-ns)</code>; the proxy user must be part of the Backup Operators and/or Administrators group on the filer.</p> <p>After you correct the error, re-enable the share (<code>enable (gbl-ns-vol-shr)</code>) to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| <p>Error: CIFS subshare check failed.</p>                                        | <p>(CIFS) The volume supports <code>filer-subshares</code> and/or <code>cifs access-based-enum</code> (ABE), and attempted to replicate subshares, subshare ACLs, and/or ABE settings between its back-end shares. This replication process, also known as <i>subshare synchronization</i>, failed. As a result, any front-end export of the failed subshare will be degraded. The output of <code>show cifs-service fqdn</code> shows all of the degraded subshares in a given <i>fqdn</i> service.</p> <p>Use <code>sync subshares from-namespace ... tentative</code> to get a full report on this issue. To repair it, use the <code>sync subshares from-namespace</code> or <code>sync subshares from-service</code> command without the <code>tentative</code> option.</p> |
| <p>Error: Cannot find credentials for connection to filer.</p>                   | <p>(CIFS) Proxy user credentials have not been properly configured for the CIFS share. These credentials must be a username and password from the Administrators group.</p> <p>Use the <code>proxy-user</code> command to add or edit these credentials, and use the <code>proxy-user (gbl-ns)</code> command to apply them to a namespace.</p> <p>After you correct the error, re-enable the share (<code>enable (gbl-ns-vol-shr)</code>) to retry the import.</p>                                                                                                                                                                                                                                                                                                              |
| <p>Error: Collision rename failed due to open file on share.</p>                 | <p>(CIFS) The share had a file that collided with an already-imported file, and the volume failed to rename it because a CIFS application has it open and locked.</p> <p>You can use <code>show cifs-service open-files</code> to find the open file, <code>close cifs file</code> to close it, and then retry the share import (with <code>enable (gbl-ns-vol-shr)</code>).</p>                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                                                                                                                     | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Error: Could not update attributes on a file/directory during import.</p> <p>Error: Detected collisions/inconsistencies during no modify import.</p> <p>Error: Device Offline</p> | <p>Failure to update file attributes can be caused by loss of connectivity during the import. Use the <a href="#">show exports</a> command and/or <a href="#">ping</a> to check the connection to the filer.</p> <p>For CIFS shares, this may indicate permissions problems. Proxy-user credentials may not have been properly configured for the CIFS share. These credentials must be a username and password from the Administrators group.</p> <p>Special, immutable directories can also cause this. The .snapshot directory (on some systems) is an example of an immutable directory, though .snapshot directories are properly ignored by the import software. To ignore other directories on this filer, use the <a href="#">gbl-ext-filer ignore-name</a> command.</p> <p>After you correct the error, re-enable the share (<a href="#">enable (gbl-ns-vol-shr)</a>) to retry the import.</p> <p>Two or more of the volume's shares had common file names that either <i>collided</i> or had NFS/CIFS naming <i>inconsistencies</i>, and this volume disallows import if it encounters either of these problems. As an example of a collision, suppose share A and share B had the same file in the same path, \docs\index.htm: these files would collide. A naming inconsistency can only occur for a directory in a multi-protocol (NFS and CIFS) namespace; the CIFS-side directory name has unicode characters that are inexpressible on the NFS-side (see the documentation for the <a href="#">character-encoding nfs</a> command). The volume must be allowed to <i>modify</i> the directory (or one of the colliding files) for the import to succeed: the directory or file must be renamed.</p> <p>All duplicate files and naming inconsistencies are recorded in the import reports for each share. These reports are named "import.job-id.share-name.share-id.rpt." Use <a href="#">show reports</a> to list all import reports and read their contents.</p> <p>Using the import report for each share, resolve all file collisions and naming inconsistencies before re-importing. Go to the filers and rename the files, move them, and/or resolve that certain file renames are acceptable. Once the issues are cleared, use the <a href="#">gbl-ns-vol reimport-modify</a> and <a href="#">modify</a> commands to allow modification (renames) on import. (If any other shares are still importing, you must wait for their imports to finish before you can use the <a href="#">modify</a> command.) To rename inconsistent NFS/CIFS directories, use the <a href="#">import rename-directories unmapped-unicode</a> command, too.</p> <p>After you correct the problem, use <a href="#">nsck ... rebuild</a> volume to reimport all shares in the volume.</p> <p>The share's back-end filer went offline for an extended time in the middle of the import. You can remove the share from the volume, or resolve the issue at the filer and retry the import.</p> <p>To retry the import, you can use the <a href="#">enable (gbl-ns-vol-shr)</a> command on this share.</p> |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                     | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Error: DFS links found on share during import.</p>                                | <p>Managed volumes do not support Distributed File System (DFS) links. To find all of the DFS links on all of a volume's shares, you can import the share(s) with <code>no modify</code>.</p> <p>Remove all DFS links from the back-end share. Then use the <code>enable (gbl-ns-vol-shr)</code> command to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <p>Error: Directory attribute collision detected during import.</p>                  | <p>A directory on this share has the same name and path as a directory on another share, but the attributes are different. (Directory attributes are permission settings for various users and groups, along with various other flags.) For example, suppose share A had a <code>\docs\img</code> directory and share B had a directory with the same name but different write permissions for the "Everyone" group.</p> <p>To allow the volume to modify directory attributes on import, you can use <code>modify</code> on the volume and <code>import sync-attributes</code> on the share. (If any other shares are still importing, you must wait for their imports to finish before you can use the <code>modify</code> command.) Then use the <code>enable (gbl-ns-vol-shr)</code> command to retry the import.</p>                                                                                                                                                                                                                |
| <p>Error: Directory collision; Unable to guarantee strict-attribute-consistency.</p> | <p>(multi-protocol) A directory on this share has the same name and path as a directory on an already-imported share, but some of the CIFS attributes are obscured for at least one of them. Obscured CIFS attributes, due to filer-generated names for the directories, are common on a multi-protocol filer. The volume requires that all attributes (for CIFS and NFS) be synchronized for duplicate directories, and that is impossible under the circumstances.</p> <p>This can only occur for NFS-only directories, with names that are illegal in CIFS. If possible, change the directory name(s) so that they are accessible from CIFS. As an alternative, you can use <code>no strict-attribute-consistency</code> to remove the requirement for strict-attribute consistency; this reduces all undiscovered CIFS attributes to zero. Once the volume has stopped importing any shares, you can do this for all shares in the volume. Then restart this share import with the <code>enable (gbl-ns-vol-shr)</code> command.</p> |
| <p>Error: Directory name collision detected during import.</p>                       | <p>A directory on this share has the same name and path as a file on an already-imported share. For example, share B has a directory named <code>/var/log</code> but share A was already imported with a file named <code>/var/log</code>.</p> <p>To allow the volume to correct this by changing the directory name on import, you can use <code>modify</code> on the volume and <code>import rename-directories</code> on the share. Alternatively, you can directly access the filer(s) and correct the problem there. Retry this share import (with <code>enable (gbl-ns-vol-shr)</code>) after you address the issue.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                         | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: Dynamic Import operation failed due to a collision.               | <p>Two or more of the volume's shares had common file/directory names that somehow <i>collided</i>, causing one of the shares to fail its import. The following collisions can cause this failure:</p> <ul style="list-style-type: none"> <li>• A file in share A has the same name and path as a file in share B.</li> <li>• A directory in share A has the same name and path as a file in share B.</li> <li>• A directory in share A has the same name and path as a directory in share B, and the directories have different attributes (such as permissions). If they had the same attributes, they would not collide.</li> <li>• A file or directory in share A has a CIFS <i>case collision</i> with a file or directory on share B, and the volume is set for <b>no cifs case-sensitive</b>. For example, "myDir/MYFILE.doc" on share A could collide with "myDir/myFile.doc" on share B.</li> </ul> <p>All duplicate files and naming inconsistencies are recorded in the import reports for the share. These reports are named "import.job-id.share-name.share-id.rpt." Use <b>show reports type Imp</b> to list all import reports, and use <b>show reports report-name</b> to read a report.</p> <p>Using the import report for this share, resolve all file collisions and naming inconsistencies before re-importing. Go to the filers and rename the files, move them, and/or resolve that certain file renames are acceptable. You can also use some share-import options to have the volume automatically rename files, rename directories, or reset directory attributes in this share during import (<b>import rename-files</b>, <b>import rename-directories</b>, or <b>import sync-attributes</b>). If you use any share-import options, use the <b>gbl-ns-vol reimport-modify</b> and <b>modify</b> commands to allow modification (renames) on import.</p> <p>Then re-import the share with the <b>enable (gbl-ns-vol-shr)</b> command.</p> |
| Error: Dynamic Import operation failed.                                  | <p>The share import failed for an undetermined reason. Run the <b>collect diag-info</b> CLI command to collect diagnostic information, then contact F5 Support.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Error: Dynamic Import operation timed out.                               | <p>An internal import operation timed out, possibly due to a filer-connectivity issue. Use the <b>show exports</b> command and/or <b>ping</b> to troubleshoot the connection to the filer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Error: Encountered file(s) with more than 1024 hard links during import. | <p>The managed volume software supports a maximum of 1024 hard links per file. One or more files on this back-end share exceed this limit. These files are recorded in the share's import report, named "import.job-id.share-name.share-id.rpt." Use <b>show reports type Imp</b> to list all import reports, and use <b>show reports report-name</b> to read a particular report. Then access the filer directly to reduce the number of hard links for all of these files.</p> <p>After you correct the problem, use <b>nsck ... rebuild volume</b> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                        | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: Export In Use By Another Switch                                  | <p>The filer share contains a hidden directory, <code>.acopia</code>, written by a different ARX. Two ARXes cannot import the same share. If the share is not imported by another switch anymore, remove the directory manually.</p> <p>If this happens to all shares after a switch replacement, the old switch's UUID was not properly applied to the replacement switch. Consult the appropriate <i>Hardware Installation</i> manual for switch-replacement instructions.</p> <p>After you correct the problem, use <code>nsck ... rebuild volume</code> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Error: Export is read-only, cannot import.                              | <p>Check the share configuration at the filer: the ARX requires read/write access throughout the share's directory tree. Use the <code>show exports</code> command to examine all permission settings at the filer.</p> <p>Use the following guidelines for permissions problems:</p> <ul style="list-style-type: none"> <li>• For NFS exports, check your back-end filer configuration: the back-end share should allow <code>root</code> access to all of the ARX's proxy IP addresses. Use the <code>show ip proxy-addresses</code> command to list all configured proxy IP addresses.</li> <li>• For CIFS shares, the switch uses the namespace's <code>proxy user</code> as its identity. The proxy user, created by the <code>proxy-user</code> command, must belong to the Administrators group. The <code>proxy-user (gbl-ns)</code> command sets the proxy user for a namespace.</li> </ul> <p>Once the permissions issue is resolved, you can re-import the share with the <code>enable (gbl-ns-vol-shr)</code> command.</p> |
| Error: Failed import initialization due to filer full condition.        | <p>The back-end share is full, so the ARX volume could not create the <code>.acopia</code> directory and/or write some small files to mark the share. Go to the filer and clear out some disk space before you retry the import.</p> <p>Once some space is free, you can use the <code>enable (gbl-ns-vol-shr)</code> command to restart the share import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <p>Error: Failed to Contact Filer.</p> <p>Error: Failed to contact filer for attribute lookup.</p> <p>Error: Failed to contact portmap service during import scan.</p> <p>Error: Failed to create a file/directory on filer.</p> <p>Error: Failed to create directory collision due to open CIFS file in path.</p> <p>Error: Failed to find valid mount version during import scan.</p> <p>Error: Failed to mount filer during import scan.</p> <p>Error: Failed to open NFS connection to filer during import scan.</p> | <p>The back-end device could not be located with the IP address configured for the filer. From <code>gbl-ext-filer</code> mode, use the <code>ip address</code> command to reset the filer's address. Use the <code>show exports</code> command, <code>expect traceroute</code>, and/or <code>ping</code> to check the connection to the filer.</p> <p>After the filer connection is re-established, you can use the <code>enable (gbl-ns-vol-shr)</code> command to restart the share import.</p> <p>(NFS) These errors indicate an NFS-server problem at the filer. Once the filer's NFS service is restored, you can use the <code>enable (gbl-ns-vol-shr)</code> command to restart the share import.</p> <p>This may indicate a full disk on the back-end filer or permissions problems. Use the <code>show exports</code> command to examine all permission settings at the filer.</p> <p>Use the following guidelines for permissions problems:</p> <ul style="list-style-type: none"> <li>For NFS exports, check your back-end filer configuration: the back-end share should allow <code>root</code> access to all of the ARX's proxy IP addresses. Use the <code>show ip proxy-addresses</code> command to list all configured proxy IP addresses.</li> <li>For CIFS shares, the switch uses the namespace's <code>proxy user</code> as its identity. The proxy user, created by the <code>proxy-user</code> command, must belong to the Administrators group. The <code>proxy-user (gbl-ns)</code> command sets the proxy user for a namespace.</li> </ul> <p>Once the permissions issue or space issue is resolved, you can re-import the share with the <code>enable (gbl-ns-vol-shr)</code> command.</p> <p>(multi-protocol) A directory on this back-end share has a case collision with an already-imported directory, and a CIFS client has a file open in the already-imported directory. For example, suppose the volume imports <code>/vol/mydir</code> from one share, a client connects and opens a file in that share (<code>/vol/mydir/myfile.exe</code>), and then the volume attempts to import a second share with <code>/vol/MYDIR</code>. The volume must mark the first share as "NFS-only" for the import to proceed, but cannot as long as the client holds "myfile.exe" open. The second share therefore fails its import.</p> <p>You can use <code>show cifs-service open-files</code> to find the open file, <code>close cifs file</code> to close it, and then retry the share import (with the <code>enable (gbl-ns-vol-shr)</code> command).</p> <p>(NFS) These errors indicate an NFS-server problem at the filer. Once the filer's NFS service is fully restored, you can use the <code>enable (gbl-ns-vol-shr)</code> command to restart the share import.</p> |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                      | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: Failed to resolve IP address for filer.                        | <p>The back-end device could not be located with the filer name or IP address configured for the filer. From gbl-ext-filer mode, use the <a href="#">ip address</a> command to reset the filer's address.</p> <p>Use the <a href="#">show exports</a> command and/or <a href="#">ping</a> to troubleshoot the connection to the filer. After the filer connection is re-established, you can use the <a href="#">enable (gbl-ns-vol-shr)</a> command to restart the share import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Error: Failed to retrieve Kerberos information.                       | <p>(CIFS) The namespace supports Kerberos authentication (see <a href="#">cifs authentication</a>), but the namespace software is unable to confirm that the share is configured to support Kerberos, too.</p> <p>Check the connection to the back-end filer with <a href="#">show exports</a> and/or <a href="#">ping</a>. Restart the import (with <a href="#">enable (gbl-ns-vol-shr)</a>) after you correct the problem.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Error: Failed to take pathlock due to internal operation in progress. | <p>The share import failed due to an internal-software conflict, possibly due to a timing issue or a brief filer-connectivity issue. Retry the import by using the <a href="#">enable (gbl-ns-vol-shr)</a> command on this share. If this error returns, contact F5 Support.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Error: Failed to unmount filer during import scan.                    | <p>(NFS) Persistent errors from a back-end share caused the mount to fail. Check the NFS service at the back-end filer. Once the filer's NFS service is fully restored, you can use the <a href="#">enable (gbl-ns-vol-shr)</a> command to restart the share import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Error: File collision detected during import.                         | <p>A file on this share has the same name and path as a file on an already-imported share. To fix this, you can manually go to the filer and rename the file, or you can set the <a href="#">modify</a> flag on this volume. By setting the <a href="#">modify</a> flag, you allow the volume to rename the file on import. (If any other shares are still importing, you must wait for their imports to finish before you can use the <a href="#">modify</a> command.) You must also have the default settings for <a href="#">import rename-files</a> and <a href="#">import rename-directories</a> on this share.</p> <p>Then restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                           |
| Error: File exists in CIFS, but not in NFS.                           | <p>(multi-protocol) The share is configured for both NFS and CIFS, but a directory that is visible in the back-end-CIFS share is not found in the NFS export. The filer probably has two different names for the directory: one for CIFS clients and one for NFS clients.</p> <p>Check the directory at the back-end share, and rename it so that both versions have the same name. Alternatively, you can set the <a href="#">modify</a> flag on this volume. By setting the <a href="#">modify</a> flag, you allow the volume to rename the directory on import. (If any other shares are still importing, you must wait for their imports to finish before you can use the <a href="#">modify</a> command.)</p> <p>You may also need to set <a href="#">import rename-directories unmapped-unicode</a> for this share; this allows the volume to rename directories whose CIFS names do not map to the character encoding for NFS. Then restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p> |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                     | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: filename collision.                                                           | <p>A file on this share has the same name and path as a file on an already-imported share. To fix this, you can manually go to the filer and rename the file, or you can set the <a href="#">modify</a> flag on this volume. By setting the modify flag, you allow the volume to rename the file on import. (If any other shares are still importing, you must wait for their imports to finish before you can use the <a href="#">modify</a> command.) You must also have the default settings for <a href="#">import rename-files</a> and <a href="#">import rename-directories</a> on this share.</p> <p>Then retry the import.</p>                      |
| Error: Filer does not have enough free space to perform import.                      | <p>(NFS) The ARX creates a temporary database on each share during the import process: there is not enough room on this share to create the database. The database requires at least 100 MegaBytes of free space.</p> <p>Clear some free space at the filer share, then restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                    |
| Error: Filer does not provide an NFS filehandle for a file in its directory listing. | <p>(multi-protocol) The filer provided a file name in an NFS REaddir call, but did not translate that file name into a filehandle in a subsequent LOOKUP call. Some multi-protocol filers behave this way when a CIFS file name has characters that are not supported by NFS; the filer returns the UTF-8 version of the file name for the REaddir call, which it later rejects in a subsequent LOOKUP call. The ARX can see the file in the directory listing, but cannot get access to the file itself.</p> <p>Rename the file at the filer share, then use <a href="#">nsck ... rebuild</a> volume to reimport all shares in the volume.</p>             |
| Error: Filer does not support specified protocols.                                   | <p>The protocol(s) configured for the back-end share are not actually supported at the filer. Use the <a href="#">show exports</a> command to check the protocols supported by the filer. Use the <a href="#">show global-config namespace</a> command to view the required protocols for the namespace. The share must support all of the namespace's protocols.</p> <p>You can remove the share from the volume (with <a href="#">no share</a>), or you can add protocol support at the back-end filer. If you add the protocol support to the filer, you can then restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p> |
| Error: Filer error during import.                                                    | <p>This may indicate a disk failure at the external filer. Correct the filer issue and retry the import (with the <a href="#">enable (gbl-ns-vol-shr)</a> command).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                           | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Error: Filer generated name collision is not supported by filer.</p>                    | <p>(multi-protocol) The share contains an entry whose filer-generated name (FGN) matches a real name in an already-imported share, or whose real name conflicts with an already-imported FGN. The volume is backed by a mix of Hitachi HNAS (BlueArc) filers and filers from other vendors, and this naming conflict is not supported for this vendor combination.</p> <p>The import report shows the name of the conflicting file or directory. The name appears with an “FC” notation. The report is named “import.job-id.share-name.share-id.rpt.” Use <a href="#">show reports</a> to list all import reports and read their contents.</p> <p>Using the import report, resolve all of these name collisions before re-importing. Go to the filer to rename the files and/or directories. Then use <a href="#">enable (gbl-ns-vol-shr)</a> to re-import the share.</p> |
| <p>Error: Filer operation returned an unexpected error, see logs for more information.</p> | <p>The back-end filer behind this share returned an error that the ARX does not recognize. You can use the <a href="#">show logs syslog</a> command to view the system log and learn more about the circumstances around the failure.</p> <p>We recommend that you contact F5 Support if you see this import error. You may be requested to run the <a href="#">collect</a> command, which assembles diagnostic information for F5 Engineering.</p> <p>After the issue is resolved, use <a href="#">nsck ... rebuild volume</a> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                                 |
| <p>Error: Filer returned invalid link count for a file.</p>                                | <p>The import failed because the back-end filer returned a link count of zero or a negative number for a file, which is invalid. A file’s link count should be one or more. The ARX syslog contains the file with the invalid link count; use <a href="#">grep “link count” logs syslog</a> to find the path. Use this path to help diagnose and correct the filer issue. Then use the <a href="#">enable (gbl-ns-vol-shr)</a> command to retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |
| <p>Error: Hard Links Inconsistent</p>                                                      | <p>(NFS) One or more files in the exported directory have hard links from outside the directory. That is, the switch tried to import a hard link to file X but detected that there was at least one more hard link to file X in some other directory, not included in the NFS export.</p> <p>Remove the hard links from the external directories and retry the share import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <p>Error: Hard Links Not Supported</p>                                                     | <p>(CIFS) Hard-links exist in a CIFS share (not supported in CIFS by the ARX).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <p>Error: I/O error encountered talking to filer.</p>                                      | <p>Use the <a href="#">show exports</a> command and/or <a href="#">ping</a> to check the connection to the filer. Restart the import (with <a href="#">enable (gbl-ns-vol-shr)</a>) after the connection is restored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <p>Error: Import database I/O failure.</p>                                                 | <p>(NFS) The ARX creates a temporary database during the import process. The database was deleted while the import was underway. This may indicate that other clients are bypassing the ARX to access the share, which is an unsupported configuration.</p> <p>You can restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                                         | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Error: Insufficient files reserved for the volume.                                                       | <p>This share contains more files than the volume can hold. Use the <a href="#">auto reserve files</a> command to automatically increase the number of files that this volume can hold as the volume grows. If you prefer to manually set the maximum files for the volume, use <a href="#">reserve files</a> to manually increase the maximum. Then restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Error: Insufficient free space to store metadata.                                                        | <p>A volume's metadata share requires gigabytes of free space; the one chosen for this volume has less than one-half gigabyte. Choose a metadata share with more free space: use the <a href="#">metadata share</a> command to configure a new metadata share.</p> <p>After you choose another metadata share, or clear up several gigabytes of free space on the current metadata share, you can use the <a href="#">enable (gbl-ns-vol-shr)</a> command to restart the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Error: Internal IPC communications failure during import.<br>Error: Internal thread error during import. | <p>These errors each indicate an internal software problem. Run the <a href="#">collect diag-info</a> CLI command to collect diagnostic information, then contact F5 Support.</p> <p>Once the issue is understood, you can restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Error: Maximum number of namehash collisions for a filename reached in a directory.                      | <p>A directory in this share has too many entries (files and/or subdirectories) whose names differ only in case (for example, "thisFile.txt," "THISfile.txt," "thisFILE.txt," and so on). The limit on case collisions for a single entry name is over 16,000. A client tried to create a new entry that would exceed the limit for a particular entry name, and the volume blocked the action with an "access denied" error.</p> <p>You can resolve this issue by accessing the volume as a client and moving as many of the file entries as possible. Create a new directory to hold many of them, or rename them to a non-matching name. For example, you could change the earlier examples to "thatFile.txt," "THATfile.txt," and so on to stop them from making a case-insensitive match with "thisfile.txt."</p> <p>The specific directory and file name appears in a syslog message labeled "ERROR_MAX_HASH_COLLISIONS." Use <a href="#">grep ERROR_MAX_HASH_COLLISIONS logs syslog</a> to search for this error in the syslog.</p> <p>Note that the colliding names are usually case collisions, but not always. The collision occurs after a mathematical conversion of the file names, called a <i>hash</i>.</p> <p>After you clear enough colliding files from the directory, you can restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p> |
| Error: Maximum Path Length Exceeded                                                                      | <p>A path to one of the files exceeds the maximum, 1024 characters. You must shorten the path(s) to import this share.</p> <p>Once all of the share's paths are below 1024 characters, you can restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                                                                                         | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Error: Metadata database I/O failure.</p> <p>Error: Metadata filer configuration is invalid. Data written has been lost, corrupting the database.</p> | <p>There was a database I/O failure for the share. This may be caused by a transient network error, or a filer problem. You can use the <a href="#">show exports</a> command to check the filer and connection for common problems.</p> <p>Once the external problem is resolved, use <a href="#">nsck ... rebuild</a> volume to reimport all shares in the volume.</p> <p>This is not an import error: it typically occurs while the volume is providing service. This condition disables the volume.</p> <p>Some of this share's metadata was lost at the volume's metadata share. This indicates that the metadata share did not synchronously write its data; it wrote the data to a cache, told the ARX that the write succeeded, and then lost the data between the cache and the disk. This is only possible on an NFS export where either</p> <ul style="list-style-type: none"> <li>• the "async" option was set, or</li> <li>• "async" is the default for the NFS implementation (as with some releases of Linux)</li> </ul> <p>CIFS shares do not have this problem.</p> <p>At the filer, set the "sync" option for the NFS export. We also recommend that you specify the "no_wdelay" option.</p> <p>Use <a href="#">nsck ... rebuild</a> volume to re-initialize the metadata share and reimport all shares in the volume.</p> |
| <p>Error: Metadata share unavailable during import.</p>                                                                                                  | <p>The switch could not contact the metadata share. Use the <a href="#">show exports</a> command and/or <a href="#">ping</a> to check the connection to the metadata share's filer. The <a href="#">show export</a> command also verifies that the share is accessible by <i>root</i> (for NFS shares) or the namespace's <a href="#">proxy-user (gbl-ns)</a> (for CIFS shares).</p> <p>After the connection is re-established, restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <p>Error: Mismatched NFS filename encoding.</p>                                                                                                          | <p>(multi-protocol) The NFS character-encoding setting for the namespace does not match the character encoding supported at the filer. If this share was imported, lost NFS files could result. Reset the namespace character encoding (using the <a href="#">character-encoding nfs</a> command) and retry the import. You can use the <a href="#">enable (gbl-ns-vol-shr)</a> command to restart the share import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <p>Error: Mount to filer failed.</p>                                                                                                                     | <p>(NFS) The switch was unable to NFS-mount the filer share. | Error: No space left on share, or share unreachable            | The ARX got an error writing a database that is created as part of the import process. This database is created on the filer share itself, so the error indicates a problem with the filer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Error: No space on back-end device.                            | Clear some free space at the filer share, then restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Error: Operation aborted at user request.                      | An administrator issued the <a href="#">cancel import</a> command to stop this share import. You can restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Error: Permission Denied                                       | <p>This indicates that the ARX did not have proper permissions to connect to the back-end filer.</p> <p>For NFS exports, check your back-end filer configuration: the back-end share should allow access to all of the ARX's proxy IP addresses. Use the <a href="#">show exports</a> command to check the filer's permissions and configuration. Use the <a href="#">show ip proxy-addresses</a> command to list all configured proxy IP addresses.</p> <p>For CIFS shares, the switch uses the proxy user for the namespace; the <a href="#">proxy-user (gbl-ns)</a> command sets these credentials. The proxy user must belong to the Administrators group.</p> <p>After the permissions problem is corrected, you can restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p> |
| Error: Protocol specific error, see logs for more information. | <p>(CIFS) The back-end filer returned an unexpected CIFS error during import. The syslog shows the specific error. Use <a href="#">show logs syslog</a> to read the syslog, or <a href="#">grep string logs syslog</a> to search for a specific string in the syslog. You may need to escalate to F5 Support.</p> <p>After you correct the error, use <a href="#">nsck ... rebuild volume</a> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                                                                                                    |
| Error: Proxy User does not map to root user via NFS.           | <p>(multi-protocol) The <i>proxy user</i> is a Windows username and password that the volume can use as its identity for share import and for policy operations. In a multi-protocol (CIFS and NFS) namespace, the proxy user on the Windows side must map to the <i>root</i> user on the UNIX side.</p> <p>You can select a new proxy user for the namespace with the command. If necessary, map the proxy user to root at the filer itself; the <i>ARX Site Planning Guide</i> has instructions for creating this mapping on common multi-protocol filers.</p>                                                                                                                                                                                                                                           |
| Error: Remove incomplete: found files on share.                | <p>An administrator failed to remove the share with <a href="#">no share</a> because client-visible files are still present on the share. Use the <a href="#">remove-file-entries</a> option to remove all of the file entries from the volume; this produces a client-visible effect, so do this with caution.</p> <p>Alternatively, you can use <a href="#">remove-share nomigrate</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: Root Squash is Enabled                                   | <p>(NFS) This indicates that the ARX did not have proper permissions to create files at the back-end filer.</p> <p>Check your back-end filer configuration: the back-end share should have <i>no-root-squash</i> set for all of the ARX's proxy IP addresses. (On some filers, you accomplish this by mapping the <i>anonymous</i> user to UID 0 (zero).) Use the <a href="#">show exports</a> command to check the filer's permission settings. Use the <a href="#">show ip proxy-addresses</a> command to list all configured proxy IP addresses.</p> <p>Once the filer's root-squash option is disabled, you can restart the import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                         |
| Error: RPC error during import scan.                            | <p>(NFS) Persistent NFS errors from a back-end share caused the import to fail. Check the NFS service at the back-end filer.</p> <p>After the filer's NFS service is fully restored, you can restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Error: Share attributes incompatible with volume attributes.    | <p>(CIFS) The CIFS attributes set for the volume (with <a href="#">compressed-files</a>, <a href="#">named-streams</a>, <a href="#">persistent-acls</a>, <a href="#">sparse-files</a>, and/or <a href="#">unicode-on-disk</a>) are not all supported at the back-end share. Use the <a href="#">show exports</a> command to check the supported CIFS attributes for the share.</p> <p>You can remove the share from the volume (with <a href="#">no share</a>) or disable the conflicting CIFS attribute(s) in the managed volume. If you elect to keep the share in the volume, use the <a href="#">enable (gbl-ns-vol-shr)</a> command to restart the share import.</p>                                                                                    |
| Error: Share does not support Kerberos authentication.          | <p>(CIFS) The namespace supports Kerberos authentication (see <a href="#">cifs authentication</a>), but this share does not. The share must support <i>extended security negotiations</i> for the import to succeed. Also, the ARX needs the correct service-principal name (SPN) for the filer; you can use <a href="#">show exports ... capabilities</a> to verify that the ARX has discovered the correct SPN for the filer, or you can use the <a href="#">spn</a> command to set it manually.</p> <p>After you ensure that the filer support Kerberos and the ARX has the filer's SPN, you can restart the import (<a href="#">enable (gbl-ns-vol-shr)</a>). Alternatively, you can remove the share from the volume with <a href="#">no share</a>.</p> |
| Error: Share type does not match namespace supported protocols. | <p>Each back-end share must support <i>all</i> of the namespace's configured protocols (any combination of NFSv2, NFSv3(/UDP), NFSv3/TCP, and CIFS). Use the <a href="#">show global-config namespace</a> command to view the namespace's protocols.</p> <p>You can remove the share from the volume (with <a href="#">no share</a>) or enable the missing service(s) at the filer. If you elect to keep the share in the volume, use the <a href="#">enable (gbl-ns-vol-shr)</a> command to restart the share import.</p>                                                                                                                                                                                                                                   |

**Table 21.1** Share Status Conditions (Continued)

| Status Condition                                                                                                                                                                                                     | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Error: Specified export is not a directory.</p> <p>Error: Specified export is too long.</p> <p>Error: Specified export not found on filer.</p> <p>Error: Stat of a file/directory failed during storage init.</p> | <p>The export name is incorrect in the external-filer configuration. Use the <a href="#">filer</a> command to change the configured name for the share/export.</p> <p>(NFS) The ARX was unable to access the attributes of a file or directory. Check the NFS service at the back-end filer. To check the ARX's connectivity to the filer and perceived permissions at the filer, use <a href="#">show exports</a>.</p> <p>You can restart the share import with <a href="#">enable (gbl-ns-vol-shr)</a> after you resolve the filer issue.</p>                                                                                                                                                                    |
| <p>Error: Storage is already in use by this switch pair.</p>                                                                                                                                                         | <p>The share is already imported into another managed volume on this switch (or its redundant peer). Evidently, the back-end share has at least one alias and it was previously imported under another name. A share can only be managed by one volume at a time, under a single name.</p> <p>From <a href="#">gbl-ns-vol-shr</a> mode in the CLI, use <a href="#">no filer</a> to detach from the back-end share. Then choose another back-end path with the <a href="#">filer</a> command, or use <a href="#">no share</a> to remove the share from the volume.</p> <p>To restart the import (with or without this share), use <a href="#">nsck ... rebuild volume</a> to reimport all shares in the volume.</p> |
| <p>Error: Storage remove failed because pending directory operations could not be flushed.</p>                                                                                                                       | <p>Someone attempted to remove a share (with <a href="#">no filer</a>, <a href="#">no share</a>, <a href="#">remove-share migrate</a>, <a href="#">remove-share nomigrate</a>, or <a href="#">remove service</a>), and an internal error caused the removal to fail. Contact F5 Support if you see this message.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| <p>Error: Unable To Connect to CIFS Share.</p>                                                                                                                                                                       | <p>The connection to the back-end CIFS share failed due to possible configuration errors or a broken connection to the back-end filer. Use the <a href="#">show exports</a> command, <a href="#">expect traceroute</a>, and/or <a href="#">ping</a> to troubleshoot the connection to the filer. Once the connection is fully established, you can restart the share import with the <a href="#">enable (gbl-ns-vol-shr)</a> command.</p>                                                                                                                                                                                                                                                                          |
| <p>Error: Unable to read file due to stale filehandle.</p>                                                                                                                                                           | <p>(NFS) The filer provided a filehandle in response to an earlier NFS call, and is now pronouncing it "stale." This is inconsistent filer behavior; it may indicate that NFS clients are bypassing the ARX to access the share. Check the filer share and correct the problem there.</p> <p>Once the filer issue is corrected, use <a href="#">nsck ... rebuild volume</a> to reimport all shares in the volume.</p>                                                                                                                                                                                                                                                                                              |
| <p>Error: Unexpected CIFS privilege check failure.</p> <p>Error: Unexpected CIFS write check failure.</p>                                                                                                            | <p>A CIFS-permission test failed at the filer for an undetermined reason. This may be a filer issue or a connectivity issue. Check the filer and the connection, and retry the share import (with <a href="#">enable (gbl-ns-vol-shr)</a>). If this error stops the import a second time, run the <a href="#">collect diag-info</a> CLI command to collect diagnostic information and contact F5 Support.</p>                                                                                                                                                                                                                                                                                                      |

| Status Condition                               | Description/Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Error: Unresolvable case-blind name collision. | <p>(CIFS) A file on this share has the same name and path as a file on an already-imported share, based on a case-blind comparison, and the volume is configured with no <code>cifs case-sensitive</code>. That is, some of the characters have differing cases, but the characters match (for example, “index.htm” matches “index.HTM”). If the volume is not case-sensitive, it cannot see the difference between the two names.</p> <p>You have three options to address this error:</p> <ul style="list-style-type: none"> <li>Manually go to the filer and rename the file.</li> <li>Set the <code>modify</code> flag on this volume. By setting the <code>modify</code> flag, you allow the volume to rename the file on import. You must wait for all the volume’s shares to finish importing before you can use this command.</li> <li>Use <code>cifs case-sensitive</code> to make the volume case-sensitive.</li> </ul> <p>Then retry the import with the <code>enable (gbl-ns-vol-shr)</code> command.</p> |
| Import Interrupted                             | <p>An administrator stopped the import with the <code>cancel import</code> command. You may be able to restart the import with no <code>enable (gbl-ns-vol-shr)</code> and then <code>enable</code>. If the import was stopped too far in the process, you must first use <code>nsck ... destage</code> to shut down the volume, remove and re-add the share, then <code>enable</code> the volume again.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Internal Error ( <i>number</i> )               | <p>Internal problem; contact F5 personnel.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Metadata Only                                  | <p>The share is designated to store namespace metadata only, so there are no client-accessible files to import. This serves as an explanation; it is not an import error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offline: Volume Disabled                       | <p>No imports are possible unless the volume is enabled. Use the <code>enable (gbl-ns, gbl-ns-vol)</code> command to enable the volume.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Offline: Volume Failed                         | <p>The metadata share for the volume failed to import. Use <code>metadata share</code> to designate a new dedicated share for metadata.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Remove Interrupted                             | <p>An administrator stopped the share removal with the <code>cancel remove</code> command. To restart the removal process, use <code>remove-share migrate</code>, <code>remove-share nomigrate</code>, <code>no share</code>, or <code>no filer</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Storage job aborted: DNAS is shutting down.    | <p>DNAS, the internal name for volume software, is shutting down. This may be the result of administrative action, such as a <code>remove service</code>, during the import. The volume has stopped running, so the import is canceled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Uninitialized (No filer assigned)              | <p>Use the <code>filer</code> command to assign a filer to the share, then retry the import.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 21.1** Share Status Conditions (Continued)

## show namespace mapping

- Purpose** Use the show namespace mapping command to view the back-end shares behind a namespace.
- Mode** (any)
- Security Role(s)** crypto-officer or storage-engineer
- Syntax** `show namespace mapping`  
`show namespace mapping namespace`  
`show namespace mapping namespace volume vol-path`
- namespace* (1-30 characters) focuses on one namespace. Without this, the command displays the shares behind all namespaces.
- vol-path* (1-1024 characters) focuses on one volume.
- Guidelines** The output is a two-column table with the namespace and volume in the left column and the physical filer shares in the right column. For **direct** volumes, this shows one line per attach point. The word, [replica-snap], appears next to any **replica-snap** shares.
- Use `show server-mapping` to show all of the filer shares behind client-side share, from a front-end service such as **cifs** or **nfs**.
- Sample(s)** `bstnA# show namespace mapping`  
shows filer shares behind all namespaces. For sample output, see [Figure 21.7 on page 21-68](#).
- `bstnA# show namespace mapping wamed volume /acct`  
shows the back-end shares behind a particular volume. See [Figure 21.8 on page 21-69](#).
- Related Commands** [show namespace](#)  
[show server-mapping](#)  
[show global-config namespace](#)

| vol3/sales      | nas2:/vol/datavol1/direct/export |

| Namespace   | Physical Server       |
|-------------|-----------------------|
| -----       | -----                 |
| wwmed:/acct |                       |
|             | das1:/exports/budget  |
|             | das3:/exports/acct2   |
|             | das7:/lhome/it5       |
|             | das8:/work1/accting   |
|             | nas1:/vol/vol1/meta1* |

Where \* denotes metadata only physical server.

**Figure 21.8** Sample Output: show namespace mapping ... volume ...

```
bstnA# show namespace mapping wwmed volume /acct
```

| Namespace   | Physical Server       |
|-------------|-----------------------|
| -----       | -----                 |
| wwmed:/acct |                       |
|             | das1:/exports/budget  |
|             | das3:/exports/acct2   |
|             | das7:/lhome/it5       |
|             | das8:/work1/accting   |
|             | nas1:/vol/vol1/meta1* |

Where \* denotes metadata only physical server.

## show namespace status

**Purpose** Use the `show namespace status` command to view the import status of a namespace.

**Mode** (any)

**Security Role(s)** `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

**Syntax** `show namespace status namespace`  
`show namespace status namespace volume vol-path`  
`show namespace status namespace volume vol-path share share-name`  
`show namespace status all`

*namespace* (1-30 characters) identifies a namespace.

*vol-path* (1-1024 characters) focuses on one volume.

*share-name* (1-64 characters) narrows the focus to a single share.

`all` displays status for all namespaces.

**Guidelines** A managed-volume share imports files from its back-end filer when it is enabled and its parent volume is also enabled. A direct-volume share does not import; it only connects to its attach points (see [attach](#)). Use [enable \(gbl-ns-vol-shr\)](#) to enable a share, and use [enable \(gbl-ns, gbl-ns-vol\)](#) to enable a volume.

This shows one table for each namespace and a sub-table for each volume. The top row of each volume table contains the name of the volume and its status. The **Status** is one of these values:

- **Enabled** - Available for client access.
- **Starting** indicates that the volume software is starting. This can occur after enabling the volume, after an ARX [reload](#), or after an [nsck ... rebuild](#).
- **Stopping** means that the volume software is shutting down. An [nsck ... destage](#) or [nsck ... rebuild](#) can cause this.
- **Migrating** shows that the volume is migrating its metadata from one share to another. The [nsck ... migrate-metadata](#) command starts a metadata migration.
- **Disabled** indicates that the volume is administratively disabled.

Shares are grouped under their volumes. For each share, this shows the **Share** name (or “metadata-share” for a metadata-only share), the name of the external Filer, the NFS Export or CIFS Share behind this namespace share, and the **Status** of the share. An [rs] appears before a [replica-snap](#) share, which holds snapshots of a standard share in the same volume.

|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Guidelines: Share Status</b> | <p>In the Status column, the following messages show the progress of a successful import:</p> <ul style="list-style-type: none"> <li>• Pending - Scheduled for import.</li> <li>• Importing - Actively inventorying the back-end storage.</li> <li>• Online - Import completed successfully, back-end storage is ready to be used. A direct share goes directly to this state.</li> </ul> <p>The following status conditions may also appear:</p> <ul style="list-style-type: none"> <li>• Disabled means that someone issued a <code>no enable</code> for the share or its volume.</li> <li>• Offline means that the volume lost contact with the back-end filer, or that someone disabled the share with <code>no enable</code>. Use <a href="#">show exports</a> to check the connection with the filer.</li> <li>• Interrupted indicates that the ARX lost contact with the filer during the import.</li> <li>• Error shows that the import failed; use <a href="#">show namespace</a> for a more-detailed error message.</li> <li>• Removing metadata appears when the share is being removed from the namespace. (Use <code>no share</code>, <a href="#">remove-share migrate</a>, or <a href="#">remove-share nomigrate</a> to remove a share.)</li> <li>• Updating Probes occurs after an upgrade to a new software release (see <a href="#">boot system</a>). The initial import of the share used a now-outdated probe to prove that the share is viable for import, so the volume is now running the latest probe test. This status should change to <code>Online</code> very quickly; examine the share with <a href="#">show exports</a> and/or <a href="#">probe exports</a> if this status persists for a long period of time.</li> <li>• Uninitialized means that no one has assigned a <a href="#">filer</a> to the share.</li> </ul> <p>Use the <a href="#">show namespace</a> command for more-detailed progress and error messages.</p> |
| <b>Sample(s)</b>                | <pre>bstnA# show namespace status all</pre> <p>shows volume shares and filer import status for all configured namespaces. For sample output, see <a href="#">Figure 21.9 on page 21-71</a>.</p> <pre>bstnA# show namespace status wwmed</pre> <p>shows volume shares and filer import status for the 'wwmed' namespace. See <a href="#">Figure 21.10 on page 21-73</a>.</p> <pre>bstnA# show namespace status wwmed volume /acct</pre> <p>shows volume shares and filer import status for the 'wwmed~/acct' volume. See <a href="#">Figure 21.11 on page 21-74</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
