## windows-mgmt-auth (gbl-ns)

**Purpose** If a CIFS service has MMC browsing enabled, only authorized Windows clients can manage the service. You can use the [windows-mgmt-auth](#) command to create a Windows-management-authorization (WMA) group, a list of Windows clients with MMC permissions, and then you can use this command to apply one or more such groups to the current namespace.

You can also use this command to select privileged CIFS clients who can access snapshots. (This command has no effect on snapshot access by NFS clients.)

Use no [windows-mgmt-auth](#) to remove a WMA group from the current namespace.

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** [windows-mgmt-auth name](#)  
no [windows-mgmt-auth name](#)

*name* (1-64 characters) identifies the WMA group.

**Default(s)** None

**Guidelines** Each WMA group has special MMC access to the namespace. The Windows clients in the group share the same MMC permissions. All [cifs](#) services backed by this namespace (if they have [browsing](#) enabled) use the WMA group(s) that you identify with this command.

You can also use WMA groups to manage CIFS-client access to snapshots. Use the [permit snapshot monitor](#) (see [permit \(gbl-mgmt-auth\)](#)) command to allow group members to view snapshots, and use the [snapshot privileged-access](#) command in any volume where the group(s) should access snapshots.

Use this command multiple times to associate multiple WMA groups with the namespace. The [show windows-mgmt-auth](#) command shows all available groups and their configurations.

If a single front-end [cifs](#) service has exports from more than one namespace, this set of WMA groups must be the same for all of the exported namespaces. (The [export \(gbl-cifs\)](#) command exports a namespace volume through CIFS.) If this command makes the current namespace inconsistent with the other namespace(s) behind the same CIFS service, the CLI prompts with an opportunity to make the same change in the other namespace(s). Enter **yes** to allow the CLI to propagate the change to the other namespace(s).

**Samples** `bstnA(gbl-ns[medarcv])# windows-mgmt-auth testers`  
`bstnA(gbl-ns[medarcv])# windows-mgmt-auth fullAccess`  
`bstnA(gbl-ns[medarcv])# windows-mgmt-auth readOnly`

associates three WMA groups to the “medarcv” namespace. A Windows client in one of these groups has the MMC permissions defined in the group. No other Windows client has MMC access to the namespace.

`bstnA(gbl-ns[medarcv])# no windows-mgmt-auth testers`  
removes a WMA group, “testers,” from the “medarcv” namespace.

**Related Commands** [windows-mgmt-auth](#)  
[show windows-mgmt-auth](#)

---

Volume

---

---

---

# attach

**Purpose** Use the **attach** command to attach (or map) a back-end directory to the current share. The ARX volume's clients can then see this back-end directory as though it was one of the volume's directories.

Use the **no** form of the command to remove the attachment.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **attach** *attach-point-directory* [**to** *physical-directory*]  
[**access-list** *map-name*]

*attach-point-directory* (1-256 bytes of UTF-8-encoded characters) is the relative pathname within the direct volume. This creates a new virtual directory, visible to clients.

**to** *physical-directory* (optional, 1-256 bytes of UTF-8-encoded characters) is the physical directory on the share relative to the share export point. If omitted, use the same name as *attach-point-directory*. To attach to the root of the back-end share, use a period (.).

*map-name* (optional, 1-64 characters) is the NFS access list to associate with the share.

**no attach** *attach-point-directory*

*attach-point-directory* (1-4096 bytes of UTF-8-encoded characters) is the relative pathname within the volume. This creates a new virtual directory, visible to clients.

**Default(s)** None.

**Guidelines** This command only applies to a share in a **direct** volume. It has no effect in a managed volume.

Use the **show server-mapping** command to view the current mappings.

Clients can mount any level of the attach-path directory. For example, suppose you create a /etc volume with a /bin/local attach point; clients can mount /etc, /etc/bin, or /etc/bin/local. Mounting a directory below that point would defeat the purpose of federating the attach points into a direct volume, so it is not supported.

**Sample(s)** `bstnA(gbl-ns-vol-shr[wwclim~/temp~zones])# attach mid-atl`  
attaches a direct-mapped directory named mid-atl to the "wwclim~/temp~zones" share.

**Related Commands** [namespace](#) -> [volume](#) -> [share](#)  
[direct](#)  
[nfs-access-list](#)  
[show server-mapping](#)

## auto reserve files

**Purpose** A managed volume has a limited number of *file credits*, where one credit is required for each of its files and directories. By default, the volume automatically increases its allocation of file credits as needed. This is a desirable situation unless the volume is used as follows:

- A **direct** volume uses this volume as it would use an external filer (with the **filer** or **managed-volume** commands), and
- the direct volume supports NFS.

The direct NFS volume cannot function properly if both of the above conditions are true; the direct volume requires an unchanging number of file credits in all of its “filers.” You can use **no auto reserve files** for a managed volume behind an NFS direct volume. This is especially important if the direct volume is on a remote ARX, which cannot detect the configuration issue.

Use the affirmative form, **auto reserve files**, to allow the managed volume to automatically reserve its own file credits.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **no auto reserve files**  
**auto reserve files**

**Default(s)** **auto reserve files**

**Guidelines** The auto-reserve-files feature is recommended for most managed volumes. You only need to disable it if the managed volume is being used as an NFS filer by a direct volume.

This command has no effect on a direct volume itself.

**Sample** `bstnA(gbl-ns-vol[ns1~/etc])# no auto reserve files`  
disables automatic file reservations in the “ns1~/etc” volume. This makes it safe to use this volume as a “filer” in an NFS-supporting direct volume.

**Related Commands** [namespace](#) -> [volume](#)  
[direct](#)  
[managed-volume](#)  
[show namespace](#)  
[show global-config namespace](#)

---

## auto sync files

**Purpose** A managed volume's metadata contains information about names and locations of all files on all of its back-end filers. A filer application, such as anti-virus software, could possibly move, delete, or rename a file without the volume's knowledge; this obsoletes the metadata about the file. If a CIFS user receives an error that indicates that a file's metadata is incorrect (the file is missing), the managed volume can automatically launch a *sync* operation to synchronize the metadata with the filer contents. Use the **auto sync files** command to allow the current volume to automatically synchronize its metadata.

Use **no auto sync files** to disable automatic synchronizations.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **auto sync files [rename-files]**  
**no auto sync files [rename-files]**

**rename-files** (optional) allows the volume to rename a newly-discovered file that collides with another file in the volume. (Two files are said to *collide* when they share the same path and name on their respective back-end shares.)

**Default(s)** disabled

**Guidelines** For NFS-only volumes, or for volumes where automatic synchronization is disabled, you can use the [sync files](#) command to manually launch a sync-files operation. You must also use the manual command for files that are created on the back-end filer; the auto-sync operation only works for missing files. Directory syncing is not automated by this command; use [sync directories](#) to synchronize the volume's metadata with new directories that may have been created at the filer.

Each auto-sync operation has a unique job ID and generates a report of its progress. The reports follow this naming convention: "auto-sync.sync-job-id.volume.rpt." Use [show reports](#) to list all reports, including auto-sync reports. To follow the progress of the auto-sync operation, you can use [tail reports report-name follow](#).

The [show sync](#) command shows the current status of one or more sync operations. You can use the [wait-for sync](#) command to wait for the operation to complete. To cancel the operation, use [cancel sync](#).

If the **rename** option is off, a newly-discovered file is not synchronized in the metadata unless its path is unique in the volume. If the option is enabled, a conflicting file is renamed as follows: "myfile.txt" on the "bills" share becomes "myfile\_bills.32.txt," assuming the auto-sync-job ID is 32.

**Guidelines: Access-Based Enumeration (ABE)** CIFS shares on some back-end filers use a security feature called *Access-Based Enumeration* (ABE) that can complicate auto-sync operations. An ABE-enabled share provides customized directory listings for every client, where the directory listing only shows files and directories where the client has read access. A managed volume examines a client's directory listing before forwarding it to the client; if a file is missing from that listing due to ABE, the volume logs that the file is "missing" and performs extra processing to find that it is still in the directory. To dampen this logging and help the volume software to work around ABE-based file listings, use the [cifs access-based-enum](#) command.

**Samples** `bstnA(gbl-ns-vol[medarcv~/usr])# auto sync files rename-files`  
allows automatic metadata synchronization in the “medarcv~/usr” volume. If any newly-discovered files would collide with other files in the volume, the volume is allowed to rename them.

`bstnA(gbl-ns-vol[medarcv~/rcrds])# no auto sync files`  
disables auto sync in the “/rcrds” volume.

**Related Commands** `namespace -> volume`  
`sync files`  
`show sync`  
`wait-for sync`  
`cancel sync`  
`cifs access-based-enum`  
`show namespace`  
`show global-config namespace`

---

# cancel import

**Purpose** The `cancel import` command stops a managed volume from importing a share.

**Modes** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `cancel import namespace ns volume vol-path share share-name`

*ns* (1-30 characters) is the namespace where the import is occurring.

*vol-path* (1-1024 characters) specifies the namespace volume.

*share-name* (1-64 characters) is the share that is being imported. Use [show namespace status](#) for a list of shares that are in the process of importing.

**Default(s)** None

**Guidelines** After canceling a share import, you must remove the share from the managed volume. You have three options:

1. Use [remove-share migrate](#) to migrate all imported files to another share in the volume.
2. Use [remove-share nomigrate](#) to avoid migrating any imported files, thus causing them to disappear from the view of the volume's clients. This command copies all imported directories to another share in the volume, and if the share is later re-imported, the directories use the new share as their home.
3. Use `no` [enable \(gbl-ns-vol-shr\)](#) and `nsck ... rebuild` to remove all imported files and directories from the volume. This causes files and directories to disappear from client view. It also forces all of the volume's NFS clients to re-mount the share (CIFS clients are briefly disconnected, which may go unnoticed).

**Sample**

```
bstnA# cancel import namespace ns volume /vol share testrun
Storage job cancelled successfully.
bstnA#
 cancels the import in progress for the "ns~/vol~testrun" share.
```

**Related Commands** [enable \(gbl-ns-vol-shr\)](#)  
[show namespace status](#)  
[remove-share migrate](#)  
[remove-share nomigrate](#)  
[nsck ... rebuild](#)

## cifs access-based-enum

**Purpose** A back-end CIFS share with *Access-Based Enumeration* (ABE) provides customized directory listings to its clients; a directory listing only contains files and folders where the client has read access. Managed-volume software mistakenly assumes that the missing (read-only) files and directories are metadata inconsistencies, and fills them back into the directory listing. Clients of the managed volume therefore see all files and directories, whether or not they have permission to read them. This defeats the purpose of ABE. Use the `cifs access-based-enum` command to inform the volume that its back-end shares have ABE enabled, and prevent the volume from revealing inaccessible files and subdirectories to its CIFS clients. (This command has a lesser effect in direct volumes, explained in the *Guidelines* below.)

Use `no cifs access-based-enum` in a volume backed by shares with ABE disabled.

**Modes** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `cifs access-based-enum [auto-enable]`  
`no cifs access-based-enum`

**auto-enable** (optional) automatically enables ABE on the back-end share when you first invoke `enable (gbl-ns-vol-shr)` and import the share. (Each of the volume's shares must have the `import sync-attributes` setting for this operation to succeed.) This ensures ABE consistency for all of the volume shares that you import from now on, and is therefore recommended.

**Default(s)** `no cifs access-based-enum`

**Guidelines** This command does not apply to a volume in an NFS-only namespace.

An ARX volume with multiple shares should have a consistent ABE setting for all of them. ABE is enforced at the back-end share, not the ARX. If one back-end share has ABE enabled and another share does not, restricted files may seem to appear and disappear if they migrate between those two shares.

The CLI prompts for confirmation if the managed volume already contains any shares with conflicting ABE settings; enter **yes** to proceed. If you use the `auto-enable` option, the volume software replicates all ABE settings between the volume's back-end shares at share-import time. (Share-import time is the first time each share is enabled, or the first time they are enabled after someone runs `nsck ... destage` or `nsck ... rebuild` on the volume.) If the volume was enabled without ABE's `auto-enable` flag, or if back-end shares otherwise have inconsistent ABE settings, you can use the `[no] cifs access-based-enum (priv-exec)` command. This `priv-exec` command enables (or disables) ABE on all of the filer shares behind a volume.

This command has no effect on any shares that have already been imported. The command sets a flag that the volume software uses during share import. The volume software otherwise ignores the flag.

In a direct volume, the back-end settings for ABE have complete control over the volume's ABE behavior. This command only controls whether or not a direct volume advertises that it supports ABE (as described below).

**Guidelines: ABE Restrictions on Shares**

After you enable ABE in the volume, the volume enforces ABE consistency on any imported shares or subshares. The `enable (gbl-ns-vol-shr)` command cannot succeed for a share if its ABE setting differs from that of the volume. The `auto-enable` flag resolves this by enabling ABE on the filer at share-import time. Each new share must have the `import sync-attributes` setting for this to succeed. For shares on filers that cannot support ABE, you can use the `cifs access-based-enum exclude` command on the share.

This last command is not generally recommended, as it creates ABE inconsistencies that are confusing to clients, but it may be necessary to support your set of CIFS filers. ABE is not supported on filers before Windows 2003 R1, NetApp 7.2.3, or EMC 5.5. ABE is also not supported on any current release of Samba.

Some filers cannot consistently support CIFS ACLs at all, and therefore preclude any ABE support in the volume. If the volume is backed with any of these filers, you must set `no persistent-acls` at the volume before it can import from them. The volume therefore ignores ACLs entirely. A volume with this setting cannot reliably support ABE, because ABE depends on the permissions settings in file ACLs.

**Guidelines: Volume Responses to the abecmd.exe Utility**

The `abecmd.exe` utility, freely available from Microsoft, can query remote shares to determine whether or not they have ABE enabled. If a front-end `export (gbl-cifs)` for this volume receives such a query, this command determines how to answer it.

The `abecmd.exe` utility cannot change the ABE setting for an ARX CIFS service, because this command controls ABE at the ARX-volume level. A change to ABE in one ARX-CIFS share would change ABE in all of the shares that export the same ARX volume.

A direct volume does not probe its shares for their ABE settings, so the `cifs access-based enum` command has a lesser effect in direct volumes. It only determines how to answer the ABE query from the `abecmd.exe` utility. The back-end shares have complete control over whether or not ABE is enabled in a direct volume.

**Samples**

```
bstnA(gbl-ns-vol[medarcv~/lab_equipment])# cifs access-based-enum
sets the "medarcv~/lab_equipment" volume for ABE processing. This is a
managed volume, so it no longer allows anyone to enable (gbl-ns-vol-shr) new
shares (and import them) with ABE disabled.
```

```
bstnA(gbl-ns-vol[medarcv~/lab_equipment])# no cifs access-based-enum
```

This volume still contains at least one share with access-based enumeration (ABE) enabled. Disabling ABE on the volume without also disabling ABE on all the volume's shares may result in user access problems.

```
Are you sure you want to disable ABE behavior for this volume? [yes/no] yes
```

sets the "medarcv~/lab\_equipment" volume to discontinue all ABE processing. The volume presumes that file listings from all clients should be consistent for a given directory, and corrects any inconsistencies it finds. This would defeat the purpose of ABE, so ABE should be disabled for all back-end shares behind the volume. From `priv-exec` mode, you can use `no cifs access-based-enum (priv-exec)` to disable ABE at all of the volume's back-end shares, too.

**Related Commands** [namespace](#) -> [volume](#)  
[cifs access-based-enum \(priv-exec\)](#)  
[cifs access-based-enum exclude](#)  
[import sync-attributes](#)

---

## cifs access-based-enum (priv-exec)

**Purpose** A back-end CIFS share with *Access-Based Enumeration* (ABE) provides customized directory listings to its clients; a client's directory listing only contains files and folders where he or she has read access. The filers behind the volume create these customized listings and the managed volume passes them back to clients. Each of the volume's shares has a separate setting to determine whether or not ABE is enabled. If ABE is enabled at the managed volume, it should also be enabled at all of the volume's backing shares. From priv-exec mode, you can use the **cifs access-based-enum** command to enable ABE on all of a volume's back-end shares and subshares at once.

Use **no cifs access-based-enum** to disable ABE on all of the back-end shares and subshares behind the volume. This is appropriate for a situation where ABE is disabled on the volume.

**Modes** priv-exec

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **cifs access-based-enum ns vol-path [force]**  
**no cifs access-based-enum ns vol-path [force]**

*ns* (1-30 characters) identifies the namespace that contains the ABE-enabled volume.

*vol-path* (1-1024 characters) specifies the managed volume where you want to fully enable ABE.

**force** (optional) tells the operation to enable ABE even on filer shares that are configured but not yet enabled.

**Default(s)** None.

**Guidelines** This command does not apply to a direct volume or a volume in an NFS-only namespace.

The ABE-enable operation produces a report to show results from each back-end share. The report name appears after you enter the command, along with a summary of the overall results.

This command is an alternative for using Microsoft's *abecmd.exe* utility on each filer. For any share with **cifs access-based-enum exclude**, this attempts to disable ABE.

The **no** form of this command disables ABE on all of the volume's back-end shares. Directly before or after disabling ABE at the volume's filers, use the **no cifs access-based-enum** command to disable ABE on the volume itself. The CLI prompts for confirmation before disabling ABE on any back-end filers; enter **yes** to proceed. If the volume has ABE disabled while a backing share has ABE enabled, clients may see the following error in their directory listings:

```
02/24/2009 04:17 PM 9 myFile.doc
The parameter is incorrect.
```

This error indicates that the file or directory ("myFile.doc" in the above example) resides on a back-end share with ABE enabled.

CIFS clients only see the results of this command if they connect *after* you invoke it.

**Guidelines: Windows Server Clusters**

Some Windows filers are nodes in a larger Windows Server Cluster. A *server cluster* is a Windows redundancy feature. The ABE-enable or ABE-disable operation only occurs on the currently-active node for any server cluster behind the volume. If the cluster fails over, ABE support is likely to be inconsistent on the newly-active node. After you run this command, go to the cluster's administrative interface and manually enable ABE; this applies the ABE setting to all nodes in the cluster. If the cluster's interface does not offer an option for ABE, use the `abecmd.exe` utility to individually set it at each node. As an alternative, you can trigger a failover at the cluster and then re-run this command.

**Samples**

```
bstnA# cifs access-based-enum medarcv /rcrds
```

```
% INFO: Changed access-based enumeration settings for 13 of 13 shares. There were 0 errors and 0 shares were left unchanged. See report 'cifsAbeChange_20100227014459.rpt'.
```

enables ABE on every filer share behind the “medarcv~/rcrds” volume. Refer to [Figure 22.1](#) for a sample report.

```
stkbgrA# cifs access-based-enum bgh /naumkeag_wing force
```

```
...
```

enables ABE on every filer share behind the “bgh~/naumkeag\_wing” volume. This also enables ABE on shares that are not yet enabled in the /naumkeag\_wing volume.

```
bstnA# no cifs access-based-enum medarcv /lab_equipment
```

```
Volume medarcv~/lab_equipment is not configured for access-based enumeration (ABE). Disabling ABE on this volume's shares will bring them into agreement with the volume configuration.
```

```
Proceed to disable ABE for this volume's shares? [yes/no] yes
```

```
% INFO: Changed access-based enumeration settings for 3 of 3 shares. There were 0 errors and 0 shares were left unchanged. See report 'cifsAbeChange_200903031058.rpt'.
```

disables ABE on every filer share behind the “medarcv~/lab\_equipment” volume. The “medarcv~/lab\_equipment” volume is now prepared to have ABE disabled.

## cifs access-based-enum exclude

**Purpose** A back-end CIFS share with *Access-Based Enumeration* (ABE) provides customized directory listings to its clients; a directory listing only contains files and folders where the client has read access. A managed volume with ABE enabled should have ABE enabled at all of its back-end shares. You can use this command to exclude a share whose backing filer cannot support ABE (such as a Samba filer). This option is designed for a tiered volume, where a lower tier of storage may be on an older or less-expensive filer that does not support ABE.

Use the `no` form to declare that the current share's back-end filer can now support ABE.

**Modes** `gbl-ns-vol-shr`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `cifs access-based-enum exclude`  
`no cifs access-based-enum exclude`

**Default(s)** `no cifs access-based-enum exclude`

**Guidelines** This command does not apply to a share in a direct volume or an NFS-only namespace. It only applies to a managed-volume share where `cifs access-based-enum` is enabled.

This command is not recommended for all sites: a managed volume should typically have consistent ABE settings with all of its back-end filers.

---

**◆ WARNING**

*If ABE is enabled on share A but disabled on share B, a client without permission to read the “xyz.doc” file sees the file disappear if it migrates to share A. The same client sees the “xyz.doc” file reappear if it migrates back to share B where ABE is disabled. This inconsistency can be confusing.*

The command is designed for volumes where the above confusion is unavoidable. To mitigate the confusion, place all ABE-excluded shares on the lowest tier of storage in the volume. Do not mix any ABE-enabled shares on the same tier. Also, do not use any combination of `place-rules` or `share-farms` that mix files between shares with different ABE settings, other than the place-rule(s) that enforce the tiering policy.

If the managed volume has ABE enabled but the current share's filer cannot support ABE, you require this command to allow an `enable (gbl-ns-vol-shr)` for the share. A managed volume stops a share from importing if the volume has ABE enabled and the back-end share does not.

The `no` form of this command informs the volume that ABE is now supportable at the back-end share. This can occur after a filer upgrade. If the volume has ABE enabled, you can use this command to remove the current share's exclusion from ABE. If necessary, you can then use the `cifs access-based-enum (priv-exec)` command to enable ABE on all the volume's back-end shares at once.

**Sample** `bstnA(gbl-ns-vol-shr[ns2~/vol1~sh5])# cifs access-based-enum exclude`  
excludes the “sh5” share from ABE support in the “ns2~/vol1” volume.

**Related Commands** [namespace -> volume](#)  
[cifs access-based-enum](#)  
[enable \(gbl-ns-vol-shr\)](#)  
[cifs access-based-enum \(priv-exec\)](#)

## cifs case-sensitive

**Purpose** Some back-end CIFS shares support case-sensitive file names, where “file.txt” and “FILE.txt” are stored as two different files. Other CIFS filers and file servers use both names to refer to the same file. (The same is also true of many CIFS-client applications.) A volume that supports CIFS cannot support case-sensitive names unless *all* of its back-end shares also support them. If that is the case, and if your CIFS clients also support them, you can enable case-sensitive naming support in this volume with `cifs case-sensitive`.

Use `no cifs case-sensitive` to stop the volume from supporting case-sensitive names.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `cifs case-sensitive`  
`no cifs case-sensitive`

**Default(s)** `no cifs case-sensitive`

**Guidelines** This command can only function in a CIFS-only namespace. It does not apply to an NFS-only namespace, and is not allowed in a multi-protocol (CIFS and NFS) namespace.

You can only enable CIFS-case sensitivity if all the back-end shares behind the volume support it.

### **Guidelines: Disabling Case Sensitivity**

You may want to add a share that cannot support case-sensitivity to a CIFS volume that previously supported it. For those situations, you can disable case sensitivity with the `no cifs case-sensitive` command. The volume must be offline to disable case sensitivity: first use `nsck ... destage` to take the volume offline, then run the `no cifs case-sensitive` command, and then re-enable all of the volume’s shares.

In a CIFS volume with case sensitivity disabled, two files or directories whose names differ only in case are said to have a *case collision*. For example, there would be a case collision between the “\dir” directory and “\Dir.” If you disable case sensitivity in a running volume, your pre-existing files and directories may have one or more case collisions. After bringing the volume’s shares back online, the volume reacts to case collisions based in the settings of certain CLI commands: if `no modify` is set, any share with a case collision fails its import; if `modify` is set, the volume uses the renaming rules set by the CLI commands below.

- `import rename-files`
- `import sync-attributes`
- `import rename-directories`

Check each share’s import report for a list of all renamed or altered files or directories in the share. Use `show reports type imp` for a list of all import reports; there is one for each imported share. Look in the import report for files and/or directories labeled “CC” (Case Collision).

---

**Samples** `bstnA(gbl-ns-vol[win-ns~/vol])# cifs case-sensitive`  
sets the current CIFS volume to support case-sensitive naming. A file named  
“myFile” can co-exist with a different file named “MyFile.”

`bstnA(gbl-ns-vol[medarcv~/rcrds])# no cifs case-sensitive`  
resets the “medarcv~/rcrds” volume so that it treats “myFile” and “MyFile” as the  
same file.

**Related Commands** [namespace](#) -> [volume](#)  
[nsck ... report metadata-only](#)

## cifs deny-symlinks

**Purpose** In a multi-protocol (CIFS and NFS) volume, CIFS clients can use symlinks created by NFS clients. For example, an NFS client can create a symlink named “alink” that points to a directory named “adir/subdir.” Any client can then access the “adir/subdir” directory through the “alink” symlink, as though “alink” was an actual directory. You can use the `cifs deny-symlinks` command to deny symlink access to the current volume’s CIFS clients. This command makes it impossible for CIFS clients to traverse a symlink.

Use `no cifs deny-symlinks` to allow CIFS clients to follow NFS symlinks.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `cifs deny-symlinks`  
`no cifs deny-symlinks`

**Default(s)** `no cifs deny-symlinks`

**Guidelines** This command is only meaningful in a multi-protocol namespace. It has no effect on a volume in an NFS-only or CIFS-only namespace.

ARX CIFS clients can never see a symlink that points to a file or directory outside their front-end export. For example, consider a CIFS share of the “\mydir\subdir” directory, where the share is named CIFSVIEW. ARX clients see the contents of “\subdir” in the root of any drive mapped to CIFSVIEW. If a symlink named “lowersub” points to “\mydir\anotherDir,” the clients of the CIFSVIEW share never see the “lowersub” symlink. The symlink would lead to a directory next to the client’s CIFSVIEW share, which may not exist on the client machine, so the managed volume does not display the link to its CIFS clients.

You can use the `nsck ... report symlinks` command to get a list of all the symlinks in a namespace or volume. You can also use the `find` command to find the target file or directory for a particular symlink. To see how many CIFS clients are using NFS symlinks, along with some related statistics, you can use the `show statistics cifs symlinks` command.

**Samples** `bstnA(gbl-ns-vol[mp-ns~/vol])# cifs deny-symlinks`  
prevents all CIFS clients from viewing or using any NFS symlinks in the “mp-ns~/vol” volume.

`bstnA(gbl-ns-vol[insur~/claims])# no cifs deny-symlinks`  
re-instates CIFS symlinks in the “insur~/claims” volume.

**Related Commands** `namespace -> volume`  
`nsck ... report metadata-only`  
`nsck ... report symlinks`  
`find`  
`show statistics cifs symlinks`

---

## cifs file-system-name

**Purpose** CIFS client applications can query a managed volume for the name of its file system. By default, the volume chooses a name based on the CIFS capabilities of its back-end shares; for example, it advertises “NTFS” if and only if all of its back-end shares can support NTFS-related features. Some client applications require specific settings in this string in order to function properly. On the advice of F5 Support, you can use the `cifs file-system-name` command to manually set the file system name for this volume.

Use `no cifs file-system-name` to return to the automatic default.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `cifs file-system-name name`  
`no cifs file-system-name`

*name* (1-16 characters) is the file-system name that this volume advertises to client applications. Use a name that is well-known, such as “NTFS” (see the *Guidelines*, below).

**Default(s)** the volume calculates an appropriate setting for the string (`no cifs file-system-name`)

**Guidelines** Use this command *only under the guidance of F5 personnel*. It has the potential to confuse client applications and cause them to malfunction.

By default, the volume advertises one of three file-system names, depending on the CIFS options supported by its back-end shares:

- NTFS - if the volume’s shares all support [named-streams](#), [persistent-acls](#), [unicode-on-disk](#), and they all preserve case in their file/directory names (“MyFile.txt” is *not* converted to “MYFILE.TXT”).
- FAT32 - if the volume’s shares support [unicode-on-disk](#) and case preservation, but not the others.
- FAT - if the volume supports none of the above options.

Some applications require “NTFS” to function properly, and do not require all of the above NTFS capabilities. For example, if one of the volume’s shares does not support named streams, the volume advertises FAT32. The Robocopy application reads the “FAT32” file-system name and assumes that the managed volume cannot support large (4GB+) files. Support for named streams is irrelevant to the application. For Robocopy to create large files in this volume, you must set “NTFS” for the volume.

In any case, use only one of the names above, in uppercase: “NTFS,” “FAT32,” or “FAT”

**Sample** `bstnA(gbl-ns-vol[insur~/claims])# cifs file-system-name NTFS`  
 advertises an “NTFS” file system for the “/claims” volume in the “insur” namespace.

**Related Commands** [namespace](#) -> [volume](#)  
[named-streams](#)  
[persistent-acls](#)  
[unicode-on-disk](#)

---

## cifs notify-change-mode

**Purpose** A CIFS filer or service can send change notifications to its clients on request. A *change notification* is an event from the CIFS service indicating some change in the file system, such as a renamed file or a new directory. This is a standard offering from CIFS implementations; file-managing applications use this to provide regularly-updated views of remote file systems. A CIFS volume on an ARX may create performance issues with this feature, since it collects change notifications from multiple back-end shares and forwards their aggregate to its clients. The volume and/or its clients can be overwhelmed with change notifications. By default, the volume reduces this traffic by ignoring any changes to a directory's subtree; it only sends notifications of changes in a directory's root. On the advice of F5 Support, you can use the `cifs notify-change-mode` command to either remove all change-notification traffic or increase it dramatically.

Use `no cifs notify-change-mode` to return to the default, which is sufficient for most volumes.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `cifs notify-change-mode {use-subtree-flag | no-changes-sent}`  
`no cifs notify-change-mode`

**use-subtree-flag** and **no-changes-sent** are a required choice:

**use-subtree-flag** causes the CIFS volume to honor a client's request for subtree notifications. By default, the volume silently ignores these client requests and only sends notifications for changes in a directory's root. You should do this only on the advice of F5 Support, as it dramatically increases the change notifications from the back-end filers to the ARX, and from the ARX to its clients.

**no-changes-sent** shuts down change notifications from the volume.

**Default(s)** `no cifs notify-change-mode`

**Guidelines** The default should be sufficient for most (if not all) installations. Use this command only on the advice of F5 Support.

**Samples** `bstnA(gbl-ns-vol[win-ns~/vol])# cifs notify-change-mode no-changes-sent`  
 disables CIFS-change notifications from the "win-ns~/vol" volume.

`bstnA(gbl-ns-vol[medarcv~/rcrds])# no cifs notify-change-mode`  
 causes the "medarcv~/rcrds" volume to support limited change notifications. Any client can request change notifications for any given directory, but the volume only sends notifications for changes in the directory's root. If the client requests subtree notifications, too, the volume silently ignores that part of the request.

**Related Commands** [namespace](#) -> [volume](#)

## cifs oplocks-disable

**Purpose** The ARX supports CIFS opportunistic locks (*oplocks*) by default. You can use the `cifs oplocks-disable` command to deny oplocks to this volume's CIFS clients.  
Use `no cifs oplocks-disable` to reinstate oplock support.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `cifs oplocks-disable [auto]`  
`no cifs oplocks-disable`

**auto** (optional) disables oplocks on a per-client basis, in response to client timeouts (see the *Guidelines*, below).

**Default(s)** the volume supports oplocks (`no cifs oplocks-disable`)

**Guidelines** This command only applies to a namespace that supports CIFS.  
The default is sufficient for most installations. Use this command only on the advice of F5 Support.

With oplocks enabled, CIFS-client A can reserve an oplock on file X. While the client holds the oplock, no other client application can write to the file; Client A can safely write to a local cache while it holds the oplock. When another client tries to write to file X, the CIFS volume holds the request, tells Client A that its oplock is revoked, takes all writes from Client A, then allows the other client to proceed.

When oplocks are disabled, the volume does not grant any oplocks to any CIFS clients.

The `auto` keyword causes the volume to enable or disable oplocks individually for each CIFS client. The volume disables oplocks for a CIFS client that fails to an "oplock break" command in 10 seconds. (The "oplock break" command tells the client to finish its writes and release the oplock to another client.) For 10 minutes, oplocks are disabled for the CIFS client. After the 10 minutes expire, the volume re-enables oplocks for the client.

**Samples** `bstnA(gbl-ns-vol[insur~/claims])# cifs oplocks-disable`  
shuts off oplock support for the "/claims" volume in the "insur" namespace.

`bstnA(gbl-ns-vol[medarcv~/rcrds])# cifs oplocks-disable auto`  
makes the "medarcv~/rcrds" volume manage oplocks on a client-by-client basis, automatically.

`bstnA(gbl-ns-vol[ns1~/])# no cifs oplocks-disable`  
reinstates the oplock feature in the "ns1~/ " volume.

**Related Commands** [namespace](#) -> [volume](#)

---

## cifs path-cache

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | <p>Each NSM processor learns about a managed volume's file and directory paths from the volume software. The volume software runs on an ACM processor. The NSM processor caches all file/directory paths as it learns them, to avoid repetitive queries to the ACM. You can use <code>no cifs path-cache</code> to stop caching these paths at the NSM processors.</p> <p>The affirmative command, <code>cifs path-cache</code>, resumes path caching at all NSM processors.</p> |

| <b>Purpose</b>          | <p>A volume that supports <i>compressed files</i> allows its clients to compress its files and preserves the file compression for policy migrations and shadow copies. If any back-end-CIFS filer does not support compressed files, you must disable the feature for its namespace volume. This applies to volumes in namespaces that support CIFS, not in NFS-only namespaces. Use the <b>no compressed-files</b> command to stop the volume from using compressed files.</p> <p>Use the affirmative form, <b>compressed-files</b>, to reinstate compressed files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Guidelines</b>       | <p>A Windows client can compress any seldom-used file to conserve on disk space (on Windows XP, right-click the file -&gt; Properties -&gt; General tab -&gt; Advanced... button -&gt; Compress ... checkbox). A volume without compressed-file support does not preserve this compression if the file migrates between back-end shares (with a <a href="#">place-rule</a>), or if the file is copied to a shadow volume (with a <a href="#">shadow-copy-rule</a>).</p> <p>You cannot enable a share if it supports compressed files and its back-end-CIFS filer does not. The enable operation fails with an error that lists all CIFS features that must be disabled, possibly including this one. Use the <a href="#">enable (gbl-ns, gbl-ns-vol)</a> command to enable all shares in a new namespace, or use the <a href="#">enable (gbl-ns-vol-shr)</a> command to enable a new share in an already-enabled namespace.</p> <p>If you remove the share(s) or upgrade the back-end filer(s), you can reinstate this feature for the volume. Use <a href="#">remove-share migrate</a> or <a href="#">remove-share nomigrate</a> to remove a share from a namespace.</p> <p>You can use the <a href="#">show exports</a> command to see all CIFS options for the share.</p> |

| <b>Purpose</b>          | Use this command to designate the current share as “critical,” so that a failover may occur if the share connection fails.<br>Use the <b>no</b> form of the command to make the share non-critical.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Mode</b>             | gbl-ns-vol-shr                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Guidelines</b>       | <p>This command is only meaningful on a switch with a redundant peer.</p> <p>If a critical share fails on the current peer <i>and</i> the redundant peer has no failures, control fails over to the other peer. A peer with “no failures” has no service-affecting software or hardware faults, and has access to all critical shares and critical routes. For example, if the current switch loses contact with a critical share but its peer has lost contact with the quorum disk, no failover occurs. (This prevents a critical-share failure from causing an unnecessary failover.)</p> <p>The ARX tests for failure with a regular ICMP ping. Every 30 seconds, the ARX sends a ping to the share’s filer. If the filer fails to respond, the ARX waits an additional 30 seconds before asking the peer if it is possible to fail over. The pings continue indefinitely at 30-second intervals. If the filer responds before the failover is initiated, the failover does not occur.</p> <p>Use the <a href="#">critical route</a> command to establish a critical route. To make a dedicated <a href="#">metadata share</a> into a critical resource, use the <a href="#">metadata critical</a> command.</p> <p>To show all critical shares and routes, use the <a href="#">show redundancy critical-services</a> command.</p> |
| <b>Samples</b>          | <pre>bstnA(gbl-ns-vol-shr[archives~/etc~s1])# <b>critical</b></pre> <p>designates the current share, archives~/etc~s1, as a critical share. If the ARX loses contact with the back-end share <i>and</i> its redundant peer has no serious issues, a failover occurs.</p> <pre>bstnA(gbl-ns-vol-shr[ns~/vol1~shareA])# <b>no critical</b></pre> <p>removes the current share from the list of critical resources.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## enable (gbl-ns-vol-shr)

**Purpose** Use the `enable` command to activate the current share.  
Use `no enable` to disable the current share.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `enable [take-ownership]`  
`no enable`

**take-ownership** (optional) applies only to a share in a managed volume (as opposed to a [direct](#) volume). This causes the managed volume to take ownership of the back-end share. Use this option only if you are sure that the share is not in active use by a managed volume on another ARX. For example, some sites use filer applications to replicate all data from one site to another; if an ARX had managed volumes at the primary site, the ARX's ownership marker (a file) would be copied to the second site. An ARX at the second site could only import the replicated share if you use the `take-ownership` option.

### ◆ Important

*The `take-ownership` option could possibly remove a share from another managed volume that is in service. Use this option only for cases where the share is spuriously marked by another ARX. The CLI prompts for confirmation if you use this option; enter `yes` to proceed.*

**Default(s)** Disabled

**Guidelines** You must enable a share for the volume to import it or otherwise use it. This is true for both managed volumes and direct volumes. We recommend that you enable all of the volume's shares first, then enable the volume with the [enable \(gbl-ns, gbl-ns-vol\)](#) command. This allows the volume to import all of the shares simultaneously, and gives the volume's clients immediate access to all of the shares at once.

### ◆ Important

*For shares backed by NetApp or EMC, you may need to access the filer directly and pre-create some qtrees or EMC quota trees. This rare configuration issue only occurs if:*

- *this is a managed volume,*
- *you want to support both free-space quotas ([freespace cifs-quota](#)), and*
- *you also want to support [filer-subshares](#) in this volume.*

*In this case, a NetApp share requires one qtree per subshare, and an EMC share must be an EMC File System with one tree quota per subshare. Pre-create the NetApp qtrees and/or EMC quota trees before you enable the share. See the [Guidelines: Subshare Replication with Free-Space Quotas](#) section of the [filer-subshares](#) documentation.*

**Guidelines (Cont.)** When a share is first imported into a managed volume, the volume generates an import report. The import reports are accessible through [show reports](#). Their names have the following formats:

```
import.share-id.share-name.job-id.rpt
```

Use [show reports report-name](#) to see its contents. See [Figure 22.2 on page 22-29](#) for a sample import report.

The `no enable` command stops using the current share in the volume. All files on the share become inaccessible to clients. This is not generally recommended in a managed volume, where it also shuts down all policy rules in the volume.

Use [remove-share migrate](#) or [remove-share nomigrate](#) to remove the share.

**Guidelines: Enabling  
a New Share in an  
Exported CIFS  
Volume**

This section only applies to a share that supports CIFS storage.

A new filer behind a running CIFS service often requires some configuration at a local Domain Controller (DC). Best practices dictate that a CIFS service is trusted to delegate CIFS connections to all of the filers behind it, and it is not trusted to delegate CIFS to any other filer. This is called *constrained delegation*. The DCs manage the CIFS service's ability to delegate, as well as the back-end filers to whom it can delegate. An authorized Windows administrator must therefore go to a DC and add this new filer to its CIFS service's "delegate to" list. If the filer's storage is exported by more than one CIFS service, the administrator must add it to the "delegate to" list for all of them.

After you enable the share, you can use [show cifs-service fqdn](#) to list the volumes exported by the *fqdn* CIFS service. For every service that exports the current volume, you can use [probe delegate-to fqdn](#) to check the DC(s) and determine whether or not delegation is properly configured for the new filer. If not, a properly authorized administrator must access the DC and add the new filer to the CIFS service's "delegate to" list.

The filer must be joined to the same Windows Domain as the above CIFS service(s), and it must support Kerberos authentication. The [show cifs-service fqdn](#) command shows the domain to which the *fqdn* service is joined.

**Guidelines: Changing  
the Maximum Files in  
a Direct Share**

This guideline only applies to a share in a direct volume.

When you enable a share in a direct volume, the volume software records the maximum number of files in the share. To increase that maximum, you must disable the share (with `no enable`), change the maximum at the back-end filer (through direct access), and then re-enable the direct share (`enable`).

**Samples** `bstnA(gbl-ns-vol-shr[archives~/multimedia~lun77])# enable`  
enables the current share.

```
prtIndA(gbl-ns-vol-shr[insur_bkup~/insurShdw~backInsur])# enable
take-ownership
```

This command allows the switch to virtualize shares that are used by other Acopia switches.

```
Allow switch to take ownership of share? [yes/no] yes
enables the current share and takes ownership of it.
```

```
bstnA(gbl-ns-vol-shr[archives~/radio~xyz])# no enable
disables the archives~/radio~xyz share.

# filer

**Purpose** Use the `filer` command to bind the current share to a back-end-filer share.  
Use the `NO` form of this command to remove the binding to any source export/share.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax: filer** `filer filer {nfs share-name | cifs share-name}+  
[access-list list-name] [cluster cCluster-name]`

*filer* (1-64 characters) is the name of the filer. Use [show external-filer](#) for a list of configured filers to choose from.

You can enter either *nfs share-name* or *cifs share-name* to identify a share at the filer. You can enter both (in any order) to specify a multi-protocol share on the filer:

*nfs share-name* (1-900 characters) is an NFS export at the filer.

*cifs share-name* (1-1024 characters) is a CIFS share at the filer.

*list-name* (optional, 1-64 characters) applies an NFS-access list to the NFS export. Use [show nfs-access-list](#) for a list of all configured NFS access lists.

*cluster-name* (optional, 1-64 characters) is only relevant if the ARX is part of a disaster-recovery (DR) configuration. In a DR configuration, there is an active ARX cluster with one set of filers and a backup cluster with a mirrored set of filers. This determines which cluster uses this *filer*. Run the `filer` command twice per share if you use DR: once to designate the filer for the active cluster, and again to determine the filer at the backup cluster. Use [show cluster](#) for a list of configured clusters. If you omit this, the command assumes that this is the local cluster.

**Syntax: no filer** `no filer [cluster cluster-name]  
no filer relocate-dirs target-share [remove-file-entries  
[verbose] [offline]]`

*cluster-name* (optional) is only relevant if the ARX is part of a disaster-recovery (DR) configuration. This specifies the cluster where the filer binding is removed. If you specify a remote cluster, the filer binding is simply removed from the remote cluster's configuration and none of the remaining options are relevant. If you omit this option, the CLI removes the binding from the local cluster.

**relocate-dirs** is required if you are disconnecting from an already-imported share in a managed volume. This is never required for a direct volume or a [replica-snap](#) share.

*target-share* is another share in the same managed volume. The volume migrates all master directories in the current share to this target.

You can enter the optional flags (**remove-file-entries**, **offline**, and **verbose**) in any order. As above, these options only apply to managed volumes and do not apply to [replica-snap](#) shares:

**remove-file-entries** removes all files from volume metadata that still reside on this back-end share.

**verbose** (optional, if you choose **remove-file-entries**) causes the operation to list all removed files in its "removeShare" report.

**offline** (optional, if you choose **remove-file-entries**) is only for back-end shares that are offline or otherwise unreachable. This forces the disconnect without scanning the back-end for its directory attributes. Relocated master directories therefore have all of their file attributes set to 0 (zero).

**Default(s)** None

**Guidelines** The filer's export/share must support all of the namespace's protocols (for example, a namespace that supports NFSv2 and NFSv3 cannot import a filer that supports only NFSv3). The [show exports](#) command shows the supported protocol(s) for each export/share, and the [show global-config namespace](#) command shows the protocol(s) supported by a namespace. Use [show external-filer](#) to list all filers.

Never import more than one instance of a given back-end share. If the filer uses aliases for its shares, the ARX assumes that each alias is a different share.

In a [direct](#) volume, you can use a managed volume as a filer instead. Use the [managed-volume](#) command to do this.

**Guidelines: Importing a NetApp Share with Multiple Qtrees**

If you choose a NetApp share with multiple qtrees, all the qtrees must have the same security style. Also, the qtrees must all use either NTFS or Unix style; managed volumes do not support qtrees with a "Mixed" security style.

A volume with such a NetApp share cannot support a [shadow-copy-rule](#), the [shadow](#) command, or the [migrate retain-files](#) option in a [place-rule](#).

### Guidelines: Removing the Filer Binding

In a managed volume, you can remove the filer binding with the simple `no filer` command before the share is first imported. The share import is triggered by a combination of `enable (gbl-ns-vol-shr)` for the share and `enable (gbl-ns, gbl-ns-vol)` for either the volume or the namespace. A direct volume does not import its shares, so you can always detach its filers with the simple `no filer` syntax. The same applies to `replica-snap` shares in a managed volume.

After the managed volume imports the share, you can use a `place-rule` to remove all files from the share. Then you use the `relocate-dirs` argument in `no filer` to relocate the share's master directories to some other share in the same volume. (A volume often has multiple copies of its directories in each share, so that it can migrate files between them; a *master directory* is the copy where the volume puts all new files.) The volume scans the current back-end share for the file attributes of these directories, to be duplicated at the *target-share*. If this is impossible because the back-end share is offline, use the `offline` flag (along with `remove-file-entries`) to create new instances of the directories with zeroed-out file attributes.

The CLI creates a “removeShare” report to show the progress of the `no filer` command. Each report is named “removeShare.*share-name*.rpt,” where *share-name* is the ARX-share name (not the name of the share at the filer).

The `no filer` command fails if any of the client-visible files in the managed volume are on the share; the `remove-file-entries` flag removes the files from the volume metadata and allows the `no filer` operation to succeed. The number of files removed appears in the removeShare report. The additional `verbose` flag adds the names of each removed file into the report. The additional `offline` flag, described above, applies to unreachable filers.

In a direct volume, you can use `no filer`, without any options, before or after you enable the share. This removes all of the share's files and directories from client view.

To remove the share configuration, you can use `no share`.

As an alternative to `no filer` or `no share` in a managed volume, you can use `remove-share migrate` to remove an imported managed-volume share, `remove-share nomigrate` to remove a managed-volume share that failed to import, or `remove-share offline` to remove a share that is unreachable.

### Samples

```
bstnA(gbl-ns-vol-shr[wwmed~/acct~bills2])# filer das3 nfs /data/acct2
binds the “bills2” share to an NFS filer share.
```

```
bstnA(gbl-ns-vol-shr[mpns~/vol~stor4])# filer nas6 nfs /vol/vol1 cifs
VOL1
binds the “stor4” share to a multi-protocol share.
```

```
bstnA(gbl-ns-vol-shr[ns1~/vol~test])# no filer relocate-dirs share4
removes the filer binding for “test,” migrating all of its master directories to
“share4” in the “ns1~/vol” volume.
```

### Related Commands

```
namespace -> volume -> share
show external-filer
show exports
show global-config namespace
no share
managed-volume
```

## filer-subshares

**Purpose** A managed volume that supports CIFS can optionally support subshares and their share-level ACLs. A *subshare* is a CIFS share inside an imported CIFS share. Through a volume that supports subshares, a properly-configured `cifs` service can pass its clients from a front-end subshare to the corresponding back-end subshare. The back-end filer can then apply the subshare's ACL to the client's actions. Use the `filer-subshares` command to support subshares at this volume.

The `no` form of this command removes subshare support from this managed volume. A volume without subshare support always connects to the root of the back-end share, thereby using the ACL defined there, whether or not the client connects to a front-end subshare.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `filer-subshares [native-names-only]`  
`no filer-subshares`

**native-names-only** (optional) causes a subshare to be “degraded” if it encounters any name collisions. A *subshare name collision* occurs when the volume attempts to replicate the subshare on a filer that already supports the same share name for a different directory. For example, suppose filer A has these two shares:

- `e:\exports` as “ESHARE” and
- `e:\exports\dirA\books` as “BOOKS.” This is a subshare of “ESHARE.”

Further suppose that filer B has these shares:

- `d:\exports` as “MYSTUFF” and
- `c:\Users\juser\Documents` as “BOOKS.” This is *not* a subshare of “MYSTUFF.”

If a managed volume imports both “ESHARE” and “MYSTUFF,” it finds the “BOOKS” subshare under “ESHARE.” It must replicate “BOOKS” on filer B at the same relative path, `d:\exports\dirA\books`. However, “BOOKS” is already defined on filer B for a directory on the C drive. The default solution to this issue is to generate a special subshare name, such as “`_acopia_BOOKS_2$`.” Use the **native-names-only** option to forbid any such generated subshare names. The volume generates a full report on subshare replication (described below) during import; if this replication fails due to a subshare-name collision like this, the report shows the subshare name(s) that collided.

**Default(s)** `no filer-subshares`

---

**Guidelines** This command only applies to a managed volume that supports CIFS.

The ARX is a proxy between front-end clients and back-end shares; it passes clients through to the back end for authentication. Share-level ACLs are created and enforced at the back-end filers. You can use `show exports ... paths` to probe for all shares on a given filer as well as the directory path behind each share. This shows you all of the share-to-subshare relationships on the filer.

Subshares require special configuration and processing on the ARX. After you use the `filer-subshares` command on a volume, you can use `export (gbl-cifs) ... filer-subshare` to export each of the subshares to your CIFS clients. When a client connects to one of these subshares, the volume passes the client connection directly to an equivalent back-end-filer subshare. The filer then uses its subshare ACL to determine the client's access privileges. Without the subshare configuration, the volume connects the client to the root of the share, and the filer uses the root share's ACL.

**Guidelines: Subshare Replication**

When you `enable (gbl-ns, gbl-ns-vol)` a volume with `filer-subshares`, the volume probes all its filer shares for subshares, and then it replicates the subshares and ACLs between those shares. The volume must ensure that all instances of a subshare have identical ACLs, so that a client has the same access privileges no matter which back-end subshare holds the desired file. For the replication to succeed, the volume must be set to `modify` and each of its shares must have the `import sync-attributes` flag raised.

The goal of subshare replication is to make all subshare definitions match as follows:

- share name,
- directory path, relative to the root of the share, and
- ACL.

The volume requires admin-level permissions to read or replicate the directory paths and subshares on the back-end filers. This is a higher level of access than you typically need for `proxy-user` credentials. You may need to change to more-privileged credentials behind the namespace's `proxy-user`, or configure the namespace with a new `proxy-user (gbl-ns)` altogether.

If synchronization is needed for a subshare but impossible due to a configuration issue (no `modify`, no `import sync-attributes`, and/or insufficient `proxy-user` permissions), the corresponding front-end subshare will be considered "degraded." Clients cannot connect to a degraded subshare.

For a `replica-snap` share, which is typically read-only, the subshare replication process cannot create directories on the share. Therefore, it cannot occur when the `replica-snap` share is enabled. Instead, the process waits for the `snapshot replica-snap-rule` to create the subshare directories, and then it defines the share name and ACL for each of them.

**Guidelines: Subshare  
Replication with  
Free-Space Quotas**

The volume-level [freespace cifs-quota](#) command makes a CIFS volume advertise free space in terms of each client's back-end storage quota. That is, if three back-end subshares each have a quota of 1G, clients with that quota see up to 3G of free space (1G for each of the three shares) instead of the actual free space. You set these free-space quotas at the back-end filers. The quotas are not replicated with other subshare data; if you use storage quotas on your back-end filers, replicate the storage quotas manually to all the back-end filers behind this managed volume.

For NetApp filers and EMC servers, manually replicate the subshares as qtrees and/or EMC tree quotas *before* you enable the volume. Do this at every NetApp and EMC share behind this managed volume. Use the same directory name, relative path, and share name for all of them. No special directories are required to set quotas on Windows servers, so you can add quotas after subshare replication on those devices.

**Guidelines:  
Subshare-Name  
Collisions**

Replicated back-end subshares use the same name as the source subshare, called the *native* subshare name, whenever possible.

The volume cannot use a native subshare name if any other CIFS share on the back-end filer is already using that name. This is called a subshare-name *collision*. For subshare-name collisions, the managed volume names the subshare with the following syntax:

```
_acopia_subshare_id$
```

where

- *subshare* is the native name of the original subshare.
- *id* is a unique integer to identify the subshare. This is unique for every subshare behind the ARX and its redundant peer.
- \$, at the end of the share name, hides the subshare name from most network clients.

You can use the **native-names-only** option to prevent any such generated names. This means that a subshare-name collision puts the front-end subshare in a “degraded” state. CIFS clients cannot connect to a degraded front-end subshare.

**Guidelines: Finding  
and Correcting  
Subshare Collisions**

A managed volume with filer subshares generates a “sync subshares” report when it and its shares are enabled. This report describes the results of the subshare-replication process. The report name has the prefix, “syncSshrNewStorageReport.” Use [show reports report-name](#) to see its contents. A sample report appears below; see [Figure 22.3 on page 22-38](#). Inconsistent subshares are flagged in this report, if any are found; you can access the filer directly to change the subshare definition or ACL, then use [sync subshares from-namespace](#) to retry the subshare-replication process.

**Guidelines:  
Subshare-ACL  
Collisions**

When two import shares have matching subshares with different share-level ACLs, they collide. For example, two shares could contain directories named “myDir\yourDir” at their roots, both shared as YOURDIR but with slightly different ACLs. The ACLs must match at all instances of the subshare, so the volume uses the directory that was chosen as “master” to choose the ACL. The *master directory* is the one that is first imported. Before you import the shares, you can use the [import priority](#) command to choose a particular share (typically the Tier-1 share) to win directory mastership wherever there is such a collision. The volume copies the ACL from the master-directory subshare to all of the matching subshares.

An ACL collision does not prevent import, or require further action.

---

**Guidelines: Windows Server Clusters** A Windows *Server Cluster* is a redundant configuration of Windows servers, called *nodes*. Subshare replication has a limitation when used on a Windows-server cluster: it can only replicate the subshares on the cluster's currently-active node. The replicated subshares and their ACLs only exist on the active node, and cannot be used after a cluster failover.

If you activate filer subshares in a volume backed by a server cluster, manually duplicate the subshares and ACLs on all nodes in the cluster. Subshare replication occurs when you [enable \(gbl-ns-vol-shr\)](#) one of the cluster's shares in the current ARX volume. After the replication is complete, duplicate the subshares and ACLs at the cluster's administrative interface; this ensures that they are on all nodes. Use the same subshare names created by the replication process, such as "Y2005" (a native subshare name) or "\_acopia\_Y2004\_4\$" (a generated subshare name).

**Guidelines: Exporting the Subshare(s)** To find and export all the subshares from the volume to your front-end CIFS service, use [sync subshares from-namespace](#).

While any of a volume's subshares are shared through a front-end CIFS service, you cannot use **no filer-subshares** in the volume.

**Guidelines: Adding New Subshares** To add a new subshare in a running volume that already supports them:

- Choose an existing directory to be exported as a subshare. If none exists, create one now:
  - If you want to support CIFS quotas ([freespace cifs-quota](#)) and the volume is backed by a NetApp filer or EMC server, go directly to the back-end filer(s) and manually create qtree(s) or quota tree(s) for the subshare. Use the same directory name and relative path for all of them. Then run [sync directories](#) to incorporate the new directory into the volume metadata.
  - If you are not supporting quotas from NetApp or EMC, connect to the front-end [export \(gbl-cifs\)](#) as a client and create its directory.
- Use [find](#) to get the master directory for the new subshare path. This tells you which filer share contains the master directory.
- Access that filer share directly and create the share-level ACL, share definition, and/or directory attributes for the subshare path.
- Use the [sync subshares from-namespace](#) command to export the directory as a subshare, and to replicate the subshare on all of the volume's filers that do not already have it. This also copies the ACL and attributes from the master directory to all stripe directories in the volume.
- If the volume is backed by any Windows Servers and it supports [freespace cifs-quota](#), access the Server(s) directly and set a path-based quota on the subshare(s).
- If the volume is backed by any Windows Server Clusters, manually duplicate the subshares and ACLs from the cluster's active node to the cluster's remaining node(s).

You cannot enable **filer-subshares** in a volume with already-enabled shares.

**Samples** `bstnA(gbl-ns-vol[medarcv~/rcrds])# filer-subshares native-names-only`  
configures the “/rcrds” volume to support CIFS subshares and share-level ACLs. The `native-names-only` option tells the volume not to generate subshare names (such as “\_acopia\_mysubshare\_1”) if subshare names collide; instead, let the replication fail and put the front-end subshare into a “degraded” state. This command raises a flag only, to be enforced when you `enable` the volume and its shares.

`bstnA(gbl-ns-vol[ns3~/vol1])# no filer-subshares`  
removes CIFS-subshare support from the “/vol1” volume.

## freespace adjust

**Purpose** If you used [freespace calculate manual](#) to manually calculate free space for this volume, you can use the `freespace adjust` command to adjust the free space that is advertised for the current share.

Use `no freespace adjust` to remove any free-space adjustment.

**Modes** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `freespace adjust [-]adjustment[k|M|G|T]`  
`no freespace adjust`

- (optional) makes the adjustment negative.

*adjustment* is the change in advertised free space.

k|M|G|T chooses the unit of measure: kilobytes, Megabytes, Gigabytes, or Terabytes. A kilobyte is 1,024 bytes, a megabyte is 1,024 kilobytes (1,048,576 bytes), and so on.

**Default(s)** `no freespace adjust`

k|M|G|T - if none of these is used, the adjustment is measured in bytes.

**Guidelines** By default, the volume calculates its free space automatically: it takes the sum of all free space on all shares, but it only counts one of the shares from a given back-end storage volume. Use the [freespace calculation manual](#) command to allow manual adjustments in the current volume, then use this command to adjust the free space for each chosen share.

You can also use [freespace ignore](#) to ignore the share in the free-space calculation. If you use this command together with `freespace ignore` on a given share, this command sets the total free space advertised by the share.

Some back-end CIFS filers (such as Windows Servers) can support free-space quotas, and these can have an effect on the free-space adjustment. You can use the [freespace cifs-quota](#) command to discover the free space available to a client at each back-end share, add up the client's available free space from all those shares, and pass the sum back to the CIFS client. This command, `freespace adjust`, then adjusts the current share's numbers based on the client's available space, not based on the total size of the share.

Use the [show global-config namespace](#) command to see if this command is set for the share.

CIFS clients only see the results of this command if they connect *after* you invoke it.

**Samples** `bstnA(gbl-ns-vol-shr[ns1~/vol~shr4])# freespace adjust -1G`  
 changes the free space that is counted for shr4; this advertises 1 Gigabyte less than the actual free space.

`bstnA(gbl-ns-vol-shr[wmed~/acct~bills])# no freespace adjust`  
 uses the actual free space for "bills" share.

---

## freespace apparent-size

**Purpose** Some sites restrict each of their clients to a single back-end share, using the ARX for occasional migrations only (that is, to migrate their entire directory tree to another share all at once). This creates a situation where the client can only use the free space on their current back-end share, not on all the shares behind the managed volume. You can use `freespace calculate dir-master-only` for this situation, which shows clients only the free space on their currently-assigned back-end share. If you use that command, you can also use `freespace apparent-size` to change the free space that is advertised for the current share.

Use `no freespace apparent-size` to report the full size of the current share to the volume's clients.

**Modes** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `freespace apparent-size size[k|M|G|T]`  
`no freespace apparent-size`

*size* is the full size to advertise for this share. After the share is imported, you can use the `show namespace` command to find its actual space.

**k|M|G|T** chooses the unit of measure: **k**ilobytes, **M**egabytes, **G**igabytes, or **T**erabytes. A kilobyte is 1,024 bytes, a megabyte is 1,024 kilobytes (1,048,576 bytes), and so on.

**Default(s)** `no freespace apparent-size`  
 k|M|G|T - if none of these is used, the adjustment is measured in bytes.

**Guidelines** By default, the volume calculates its free space automatically: it takes the sum of all free space on all shares. Use the `freespace calculation dir-master-only` command to advertise only the free space on a single back-end share to any client. The single back-end share is the one with the *master* for the client's front-end-share path; all back-end *stripe* directories are excluded. Then you can optionally use this command to set the advertised free space for each share.

If the back-end share uses up the free space you advertise with this command, but is not actually full, clients see 0 (zero) free space.

Use the `show global-config namespace` command to see if this command is set for the share.

**Samples** `bstnA(gbl-ns-vol-shr[insur~/claims~shr1-next])# freespace apparent-size 2460M`

changes the free space that is advertised for shr1-next; this advertises free space as though the share's total size is 2460 Megabytes (2.4 Gigabytes).

`stoweA(gbl-ns-vol-shr[lodges~/skiPatrol~stoweMtn])# no freespace apparent-size`

uses the actual free space size for "stoweMtn" share.

| <b>Purpose</b>                                              | The volume's free space, as seen by clients, is the sum of all free space in its back-end shares. This is misleading in installations where clients only access a single back-end share behind the volume; such clients are restricted to that single share, and should therefore only see the free space from that share. The single back-end share is said to hold the front-end share's <i>master</i> instance; replica shares on other back-end filers are called <i>stripes</i> . To show clients the free space in only the master back-end share, use the <code>freespace calculation dir-master-only</code> command.<br><br>Use the <code>no</code> form of the command to show clients the sum of all free space on all back-end shares behind this volume.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Mode</b>                                                 | <code>gbl-ns-vol</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Default(s)</b>                                           | <code>no freespace calculation dir-master-only</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>                                           | This command is useful in a managed volume with home directories, or a managed volume that is migrating files once (from one share to another). This only affects the client view of the volume's free space. It has no effect on the free space perceived by the policy engine.<br><br>A <a href="#">direct</a> volume does not support this type of free-space calculation.<br><br>The master share is the back-end share that holds the master instance of the front-end share's directory. This is the root of the <a href="#">export (gbl-cifs)</a> to which the client connected. This could be the root of the entire volume or it could be a CIFS subshare.<br><br>You may want to advertise a fixed size for each share, perhaps to ensure that the free-space seen by a client is consistent if his or her directory tree migrates from one share to another. For each share, you can set an "apparent" space size with the <a href="#">freespace apparent-size</a> command.<br><br>Use the <a href="#">show global-config namespace</a> command to see the volume's configuration settings for free space. |
| <b>Guidelines:<br/>Alternative<br/>Free-Space Reporting</b> | The <a href="#">freespace calculation manual</a> command is an alternative form of free-space calculation where you can manually adjust the free-space numbers from each share. If you set the volume for manual free-space calculation, you can exclude shares with the <a href="#">freespace ignore</a> command. You can also adjust the free-space number for a share (whether or not its actual free space is ignored) with the <a href="#">freespace adjust</a> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Samples</b>                                              | <code>bstnA(gbl-ns-vol[insur~/claims])# freespace calculation dir-master-only</code><br>changes the <code>/claims</code> volume so that it only shows the free space from one back-end share rather than all of them.<br><br><code>bstnA(gbl-ns-vol[wmed~/acct])# no freespace calculation dir-master-only</code><br>returns the <code>/acct</code> volume to the default. This volume reports the total free space to its clients, summing up the free space in all of its back-end shares.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Purpose</b>                                              | <p>The volume's free space, as seen by clients, is the sum of all free space in its shares. By default, the volume finds the back-end storage volume for each of its shares and, if two or more of its shares draw from the same back-end storage volume, it counts the free space from only one of them. Use the <code>freespace calculation manual</code> command to remove this automation, permitting you to manually decide which shares to ignore.</p> <p>Use the <code>no</code> form of the command to automatically detect multiple shares from the same back-end storage volume.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Syntax</b>                                               | <p><code>freespace calculation manual</code><br/> <code>no freespace calculation manual</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Default(s)</b>                                           | <code>no freespace calculation manual</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>                                           | <p>An NFS volume uses a share's file-system ID (FSID) to identify the storage volume behind the share. A CIFS volume uses the share's Volume Serial Number. By default, only one share is counted if two or more shares have matching IDs.</p> <p>If you set the volume for manual free-space calculation, you can exclude shares with the <code>freespace ignore</code> command. You can also adjust the free-space number for a share (whether or not its actual free space is ignored) with the <code>freespace adjust</code> command.</p> <p>Some back-end CIFS filers (such as Windows Servers) can support free-space quotas, and these can affect the free-space calculation. You can use the <code>freespace cifs-quota</code> command to discover the free space available to a client at each back-end share, add up the client's available free space from all those shares, and pass the sum back to the CIFS client. The <code>freespace adjust</code> command then adjusts a share's free-space numbers based on the client's quota, not based on the total size of the share.</p> <p>Use the <code>show global-config namespace</code> command to see the volume's configuration settings for free space.</p> |
| <b>Guidelines:<br/>Alternative<br/>Free-Space Reporting</b> | <p>The <code>freespace calculation dir-master-only</code> command is an alternative form of free-space calculation where the volume only shows the free space in one back-end share behind the volume. It chooses the share that holds the master instance of the client's current directory. This is useful for volumes where a client's directory tree is exclusively on one back-end share at any given time. If you set the volume for this free-space calculation, you can also set the client-visible space on each of the volume's shares with the <code>freespace apparent-size</code> command. You cannot use <code>freespace adjust</code> or <code>freespace ignore</code> with the <code>freespace calculation dir-master-only</code> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Samples** `bstnA(gbl-ns-vol[ns1~/])# freespace calculation manual`  
includes all shares, allowing you to manually ignore some shares.

`bstnA(gbl-ns-vol[wwmed~/acct])# no freespace calculation manual`  
reverts to automatic free-space calculations. The automatic calculation notes the back-end shares that draw from the same storage pool, and each back-end storage pool only once.

## freespace cifs-quota

**Purpose** A managed volume's free space, as seen by clients, is the sum of all free space in its back-end shares. By default, this does not take into account any storage quotas on any back-end CIFS servers; if a 100G back-end share has a quota of 1G, the client sees 100G of free space when the share is empty. You can use the `freespace cifs-quota` command to take the back-end quotas into account, so that CIFS clients with a 1G quota only see 1G of space and connections to a CIFS subshare with a 5G quota see only 5G of space. With this option enabled, clients see the sum of the quota-based free space on the volume's back-end shares, not the sum of the full free space.

Use the `no` form of the command to show all clients the full free space, ignoring all back-end quotas.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `freespace cifs-quota`  
`no freespace cifs-quota`

**Default(s)** `no freespace cifs-quota`

**Guidelines** This command is only useful in a managed volume that supports CIFS. It is not supported in a `direct` volume, or one that supports only NFS (see [protocol](#)).

Back-end filers can support one or two forms of storage quota:

- *path-based* quotas, which affect a particular directory path.
- *user-based* quotas, which allow each client to use only a limited amount of storage in a particular storage pool.

This command, `freespace cifs-quota`, makes both of these quota types visible to the ARX volume's clients. If a given client is allotted a total of 4G on the volume's back-end filers, due to path-based quotas and/or the client's user-based quotas at those filers, the client only sees 4G of space.

Use the `show global-config namespace` command to see the volume's configuration settings for free space.

CIFS clients only see the results of this command if they connect *after* you invoke it.

**Guidelines:  
Relationship of  
Front-End Shares to  
Back-End Quotas**

Path-based quotas are applied to back-end paths, so the free space that the client sees depends on the front-end CIFS share to which they connect. There are two major forms of front-end CIFS share:

- An [export \(gbl-cifs\)](#) is a full share of the entire volume, and
- An [export \(gbl-cifs\) ... filer-subshare](#) is a subshare.

If a CIFS client connects to a full share (or any path within a full share), the client sees the free-space quotas set at the imported path (or root) of the volume's back-end shares. If the client connects to a subshare, the client sees the free-space quotas set at its back-end subshare paths.

When each subshare is dedicated to a single client (as with a home-directory application), you can use path-based quotas at each back-end subshare. Then the `freespace cifs-quota` command causes the ARX volume to advertise those quotas to its clients.

◆ **Note**

---

*In all cases, we recommend setting specific path-based quotas at each back-end share or subshare to which your CIFS clients connect. For NetApp, this means that each share or subshare must be its own qtree. For EMC, the share or subshares must reside in an EMC File System with quotas set at the import share or at each subshare. For Windows, set a path-based quota at the import share or at each subshare.*

**Guidelines: NetApp  
and EMC with Filer  
Subshares**

Free-space quotas (this command) and [filer-subshares](#) are difficult to use together in a volume backed by either NetApp or EMC. A NetApp only supports path-based quotas on its qtrees, and an EMC server only supports them in a quota tree inside a File System. Each qtree or quota tree gets a single quota. As mentioned above, each subshare requires a path-based quota for proper free space reporting. Therefore, each subshare path must be backed by one qtree or quota tree. This is required for CIFS clients to see the space that they are allowed to use.

The ARX volume automatically replicates its subshare directories to all of its back-end filers. The replication process cannot safely presume that you want a full qtree or quota tree behind these replicated directories, so it can only create the directory itself. Therefore, the subshare-replication process creates directories on NetApp and EMC that cannot support path-based quotas.

For NetApp or EMC, pre-create the qtrees and/or quota trees instead of relying on the ARX volume's subshare-replication process. Do this before you import any storage from the back-end filer(s), as described in the [Guidelines: Subshare Replication with Free-Space Quotas](#) section of the [filer-subshares](#) documentation.

If subshares are already configured as plain directories on your back-end NetApp or EMC, and you want to convert them to qtrees or EMC quota trees, contact F5 for guidance.

**Guidelines: Windows  
Servers with Filer  
Subshares**

You must also set path-based quotas on all Windows servers where subshare-replication occurs. The subshare-replication process does not replicate Windows-quota settings along with other subshare settings. Unlike NetApp and EMC, you can set the quotas on Windows servers after subshare replication is complete; you do not need to pre-create any special directories.

**Guidelines: Manually Adjusting the Reported Free Space** You can also manually ignore the free space on some of the volume's back-end shares, or adjust the advertised free space for one or more shares. Use the [freespace calculation manual](#) command in the volume, then use [freespace ignore](#) and/or [freespace adjust](#) in each share. The adjustment from [freespace adjust](#) is applied to the back-end quota, not to the total size of the back-end share.

**Guidelines: Back-End Shares That Draw from the Same Storage Pool** An ARX volume may import two or more shares that are affected by the same free-space number, and this creates errors in free-space reporting. Whenever the [freespace cifs-quota](#) feature is enabled, the ARX volume presumes that a path-based quota is set on all of its back-end shares; it therefore counts the space from each share separately. For example, suppose shares HUEY, DEWEY, and LOUIE all draw from drive E on the same Windows server, and an ARX volume imports all three of them. The volume also adds together all of their free space. This creates an incorrect sum if

- there is no quota (all three shares report the full space of the E drive),
- there is a user-based quota (all shares report the full space allowed to the client), or
- all three shares inherit the same path-based quota from a common ancestor, such as E:\.

Specific path-based quotas for each share, recommended earlier, helps to solve this problem. Additionally, avoid any user-based quotas or common path-based quotas altogether.

If this is not possible, use [freespace ignore](#) to ignore each imported share from a common storage pool except one. For example, ignore the freespace on any two of the three shares (such as HUEY and DEWEY).

**Guidelines: Alternative Free-Space Reporting** The [freespace calculation dir-master-only](#) command is an alternative form of free-space calculation where the volume only shows the free space in one back-end share behind the volume. It chooses the master back-end share for the front-end share to which the client connected. This is useful for volumes where a client's directory tree is exclusively on one back-end share at any given time. If you use this free-space calculation technique, you can also set the client-visible space on each of the volume's shares with the [freespace apparent-size](#) command.

**Samples** `stoweA(gbl-ns-vol[lodges~/skiPatrol])# freespace cifs-quota`  
changes the /skiPatrol volume so that it detects path-based and/or user-based quotas on its back-end shares, and reports only the free space that is allotted to each client.

`provA(gbl-ns-vol[provMed~/rns])# no freespace cifs-quota`  
returns the /rns volume to the default. This volume reports the total free space to its clients, without requesting quota-based free space from its back-end filers. If the back-end filers do not support any CIFS quotas, this setting reduces traffic between the managed volume and its filers.

## ignore-sid-errors

**Purpose** In some cases, a back-end-CIFS filer does not recognize a Security ID (SID) on a migrated file. CIFS filers typically return an error and reject the file with the unknown SID; the volume therefore assumes that the migration failed and keeps the file on its original share. Some file servers, however, can be configured to return an error and *accept* the file anyway. EMC Celerra servers have shown this behavior in lab testing. You can use the `ignore-sid-errors` command to ignore these errors from such a file server.

To react to SID errors by canceling the file migration, use `no ignore-sid-errors`.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `ignore-sid-errors`  
`no ignore-sid-errors`

**Default(s)** `no ignore-sid-errors`

**Guidelines** This command does not apply to an NFS-only namespace.

SID errors occur for a SID that is unknown at the destination file server. The SID may be unknown because it came from another file server with Local Groups or Local Users. You can use [sid-translation](#) to translate all local SIDs (after some preparation at the filer servers). However, this translation could fail if the filer servers are not fully prepared to support Local Groups.

The command causes the share to ignore certain SID errors from its back-end file server and assume that the migration to the file server succeeded. The SID errors, in response to the CIFS ‘set security descriptor’ request, are STATUS\_INVALID\_SID, STATUS\_INVALID\_OWNER, and STATUS\_INVALID\_PRIMARY\_GROUP. When most filers return these errors, they also reject the file. Use this only for file servers that accept the file in spite of the error.

### ◆ Important

*If you use the `ignore-sid-errors` command, be sure that the filer is configured to accept the file (or directory) itself in spite of any SID errors. If the filer returns a SID error for a file and then drops it, the file is lost if the ARX share is set to `ignore-sid-errors`.*

**Samples** `bstnA(gbl-ns-vol-shr[medarcv~/rcrds~bulk])# ignore-sid-errors`  
 causes the volume to ignore any SID errors from the file server behind the “bulk” share.

`bstnA(gbl-ns-vol-shr[insur~/claims~shr1-old])# no ignore-sid-errors`  
 causes the “shr1-old” share to acknowledge any SID errors from its filer. If the policy engine gets a SID error when it tries to migrate a file or directory, the policy engine cancels the migration.

## import priority

**Purpose** A managed volume imports files and directories as its clients randomly access them, making file and directory mastership also random. For example, suppose a client accesses “/bigDir/latest.txt” from a volume with two shares, A and B. Both shares contain a “/bigDir” directory and share B contains the “/bigDir/latest.txt” file. This causes the volume to import the share B instance of “/bigDir” first, so that share B wins the directory conflict. The directory on share B becomes the *master directory*. The master directory keeps its name and attributes, but the *stripe directory* in share A may need to have its attributes or name changed for a successful import. You can use the `import priority` command to set a priority for the current share, so that you determine which shares win these import conflicts. If two shares have different priorities, the higher-priority share wins the conflict.

The volume imports its shares in their priority order; the volume waits for all shares of priority A to complete their imports before it begins importing the share(s) of priority B.

Use the `no import priority` command to reduce the share to the lowest priority.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `import priority number`  
`no import priority`

*number* (1-65535 characters) is the priority for the current share. The highest priority is 1 (one); a share with a priority of 1 wins any import conflict with any lower-priority share.

**Default(s)** 65535

**Guidelines** This command is strongly recommended for any volume with tiered shares, where one share or set of shares is considered faster and/or more-reliable than the rest. The master instances of all directories should reside on the volume’s reliable Tier 1 shares, so that clients can reliably access them. An `import priority` of 1 on the volume’s Tier 1 shares ensures that, wherever there is a directory collision, the Tier 1 share gets the master directory.

If a single share has the highest priority in the volume, it wins every import conflict and does not require any other import commands (such as `import rename-directories`, `import rename-files`, or `import sync-attributes`). For any given collision, those commands are only relevant for the lower-priority share.

Tiering is implemented with two or more file-placement rules (`place-rule`) that move higher-priority files to the Tier 1 shares and lower-priority files to other shares. Best practices dictate that you also create a `place-rule` that puts *all* the volume’s master directories onto its Tier 1 shares, not just the directories that collided on import. To do this, create a `filename-fileset` that recursively matches everything in the volume (`path exact /` and `recurse`), and use the `from (gbl-ns-vol-plc)` command to have that fileset match directories and promote them.

The volume imports any shares with the same priority in parallel.

---

**Guidelines: Import Priority Only Applies to the Current Volume**

If multiple volumes are importing their shares at the same time, the import priorities in one volume have no effect on the import priorities in the other volume. For example, if volume /usr has one or more shares at priority 1 and volume /var has shares at priority 100 (the highest priority in the volume), the priority-100 shares in /var may import at the same time as the priority-1 shares in /usr.

**Guidelines: Share Roots**

The first-configured share is assigned the master for the volume's root directory, and the import priority does not change this. To control directory mastership at the volume's root directory, use a [place-rule](#) that moves all master directories to your chosen share or [share-farm](#), as described above. Such a place rule ensures that all master directories always reside on the share or share farm where you want them.

**Samples**

```
bstnA(gbl-ns-vol-shr[medarcv~/lab_equipment~equip])# import priority 1
```

sets the highest priority for the "equip" share. If any files or directories in this share collide with those of a lower-priority share, this share wins the conflict and gets the master instance of the file or directory.

```
bstnA(gbl-ns-vol-shr[ns1~/vol~shr4])# no import priority
```

resets the 'shr4' share to the lowest possible priority.

[import sync-attributes](#)

## import rename-directories

**Purpose** There are some cases where it is necessary for a managed volume to rename a directory on import:

- It *collides* with an already-imported directory. That is, it has the same name as a directory from an already-imported share, but different file attributes.
- It collides with an already-imported *file* with the same name.

If the managed volume is allowed to [modify](#) files and directories during import, it renames these directories by default. Use the `no import rename-directories` command to prevent these directory renames in the current share, potentially causing this share's import to fail for directories that collide.

Use `import rename-directories` to permit the managed volume to rename directories in this share.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `no import rename-directories [unmapped-unicode]`  
`import rename-directories`

**unmapped-unicode** (optional) causes the import to rename directories with Unicode-only characters in their names. This occurs at multi-protocol (CIFS and NFS) sites where [character-encoding nfs](#) was set at a non-Unicode standard (such as UTF-8), but CIFS users named their directories with Unicode characters. This is off by default to protect against unexpected renames in a large multi-protocol volume.

**Default(s)** `import rename-directories`

**Guidelines** In a managed volume, two same-named directories from different shares are aggregated by default: the volume presents a single directory to its clients, with all the files from both directories. The directories collide, however, if their file attributes (such as permission settings and group ownership) are different, or if the directory's name is the same as an already-imported file. The gbl-ns-vol [modify](#) command configures the volume to rename collided directories. The `no import rename-directories` command disallows directory renames in this particular share, and instead causes one of two reactions to a directory collision:

- for a collision with a file: fail the import for this share.
- for a collision with a directory: if `import sync-attributes` is set, synchronize the attributes of this share's directory with the already-imported directory. Otherwise, fail the import for this share.

To change the rules for modifying files in this share, you can use the [import rename-files](#) command.

This option is only relevant in the second-imported share and any subsequently-imported shares. If two shares are imported together with different import priorities (see [import priority](#)), the share with the higher priority always imports first.

**Guidelines:  
Unmapped Unicode**

If a multi-protocol filer uses single-byte character encoding for its NFS names, it typically permits its CIFS clients to use multi-byte characters in their directory names. The multi-byte characters are not mappable from CIFS to the NFS-character encoding; the filer typically creates a filer-generated name (FGN) that NFS clients can use to access the directory. On some filers, the NFS FGN bears no apparent resemblance to the CIFS-side name.

A multi-protocol volume does not allow CIFS names with non-mappable characters, so this naming problem causes an import failure by default. If you set the `unmapped-unicode` option, the volume can rename any such directories on import.

Shares with this problem typically fail their initial import because of the default. You can use `show reports import-report` to see which directories have non-mappable characters, then decide to either manually rename the directories at the filer or allow the volume to do it on the next import. Then retry the import.

**Guidelines: Renaming  
Format**

For cases where directory renames are allowed (`import rename-directories`, the default), the managed volume renames directories using the following syntax: `dirName_shareName-importId[-index][.ext]`.

- *dirName* is the base name of the directory, not including any extension it may have. If it has any characters that are non-mappable between CIFS and NFS, it contains “(U+nnnn)” in place of each non-mappable character. The *nnnn* is the Unicode number for the character, shown in hexadecimal format. The name is truncated if it exceeds 256 characters. For example, “dir(U+30D2)(U+30AA)\_myshare-2.”
- *shareName* identifies the namespace share.
- *importId* is an internal identifier for the import job.
- *-index* only appears if multiple files or directories map to this name. It is unique for each such file or directory (for example, “renamedDir\_1,” “renamedDir\_1-1,” “renamedDir\_1-2,” and so forth).
- *.ext* is the original extension for the directory, if there was one.

**Guidelines: A “no  
modify” Import**

You can run a mock import of each share to review all directory-naming collisions before actually importing the share. Before you enable a share and start its import, you can disable all volume modifications with `no modify`. This prevents the volume from changing anything in its shares, and also prevents client access to the volume. Then enable the share to invoke the “no modify” import (with `enable (gbl-ns-vol-shr)`). After the “no modify” import finishes, review the share’s import report for naming collisions (as well as any other import issues) and manually correct each issue at the back-end filer. Use `show reports type Imp` to list all import reports, and `show reports report-name` to read one.

If there were no issues, you can run the `modify` command to activate the volume and the import is finished. Otherwise, remove the share from the volume (with `remove-share nomigrate`), then add the share back into the volume to retry the import.

**Guidelines: Recovery  
from Import Failure**

If an actual import fails because a directory rename was disallowed, you can use `remove-share nomigrate` to remove the share from the volume. After the share is removed, you can fix the collisions directly on the filer and then re-import the share into the volume.

**Samples** `bstnA(gbl-ns-vol-shr[wmed~/acct~bills])# no import rename-directories`  
disables the renaming of directories in the ‘bills’ share during an import. If a directory in this share collides with a file in an already-imported share, this share import fails. If it collides with a directory, the share import only succeeds if the [import sync-attributes](#) command is set to allow the volume to synchronize the directory attributes. If it has any character that is unsupported by the [character-encoding nfs](#) setting, the import fails.

`bstnA(gbl-ns-vol-shr[ns1~/vol~shr4])# import rename-directories`  
enables the renaming of directories in the ‘shr4’ share during an import.

`bstnA(gbl-ns-vol-shr[insur~/claims~shr1-old])# import rename-directories unmapped-unicode`  
permits the ‘insur~/claims~shr1-old’ share to rename all directories with non-mappable characters in their names.

## import rename-files

**Purpose** This command applies only to a managed volume. When a file from the current share has the same name as a file or directory from an already-imported share, the file is said to *collide*. If the managed volume is allowed to [modify](#) files and directories during import, it renames collided files by default. Use the `no import rename-files` command to prevent these file renames in the current share, causing this share's import to fail for files that collide.

Use `import rename-files` to permit the volume to rename files in this share.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `no import rename-files`  
`import rename-files`

**Default(s)** `import rename-files`

**Guidelines** If the managed volume is allowed to [modify](#) files that collide, it renames those files by default. You can use the `no import rename-files` command to change this default for the current share; this causes the current share to fail its import if any files collide.

If the import fails, you can use [remove-share nomigrate](#) to remove the share from the volume. After the share is removed, you can fix the collisions directly on the filer and then re-import the share into the volume.

You can also use the [import rename-directories](#) and [import sync-attributes](#) commands to set the rules for directory collisions in this share.

This option is only relevant in the second-imported share and any subsequently-imported shares. If two shares are imported together with different import priorities (see [import priority](#)), the share with the higher priority always imports first.

**Guidelines: Renaming Format** For cases where file renames are allowed (`import rename-files`, the default), the managed volume renames directories using the following syntax:

*fileName\_shareName-importId[-index][.ext]*.

- *fileName* is the base name of the file, not including any extension it may have.
- *shareName* identifies the namespace share.
- *importId* is an internal identifier for the import job.
- *-index* only appears if multiple files or directories map to this name. It is unique for each such file or directory (for example, “renamedFile\_1.doc,” “renamedFile\_1-1.doc,” “renamedFile\_1-2.doc,” and so forth).
- *.ext* is the original extension for the file, if there was one.

**Guidelines: A “no modify” Import**

You can run a mock import of each share to review all file-naming collisions before actually importing the share. Before you enable a share and start its import, you can disable all volume modifications with `no modify`. This prevents the volume from changing anything in its shares, and also prevents client access to the volume. Then enable the share to invoke the “no modify” import (with `enable (gbl-ns-vol-shr)`). After the “no modify” import finishes, review the share’s import report for naming collisions (as well as any other import issues) and manually correct each issue at the back-end filer. Use `show reports type Imp` to list all import reports, and `show reports report-name` to read one.

If there were no issues, you can run the `modify` command to activate the volume and the import is finished. Otherwise, remove the share from the volume (with `remove-share nomigrate`), then add the share back into the volume to retry the import.

**Samples**

```
bstnA(gbl-ns-vol-shr[wwmed~/acct~bills])# no import rename-files
```

disables the renaming of files in the ‘bills’ share during an import. If a file in the ‘bills’ share collides with an already-imported file or directory, the volume does not import the ‘bills’ share.

```
bstnA(gbl-ns-vol-shr[ns1~/vol~shr4])# import rename-files
```

enables the renaming of files in the ‘shr4’ share during an import.

## import sync-attributes

**Purpose** This only applies to a managed volume. When a directory from the current share has the same name as a directory from an already-imported share, but different file attributes, the directory is said to *collide*. If the volume is allowed to [modify](#) files and directories during import, it renames collided directories by default. Use the `import sync-attributes` command to allow the managed volume to instead synchronize the directories' attributes, rather than renaming them.

Use the `no` form of the command to disallow attribute synchronization for directories.

**Modes** `gbl-ns-vol-shr`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `import sync-attributes`  
`no import sync-attributes`

**Default(s)** `no import sync-attributes`

**Guidelines** In a managed volume, two same-named directories from different shares are aggregated by default: the volume presents a single directory to its clients, with all the files from both directories. The directories collide, however, if their file attributes (such as permission settings and group ownership) are different. The `gbl-ns-vol modify` command, along with the default for [import rename-directories](#), configures the volume to rename collided directories. This command provides an alternative for the current share: synchronize the directory attributes instead of renaming.

For the root directory of each share, renaming is not an option. You can use this option to synchronize all root-share attributes automatically, or you can synchronize the attributes manually at the filers (before the import). As an alternative, you can disable all volume modifications with `no modify`, review each share's import report for attribute collisions (as well as any other import issues), manually correct these issues at the filer, then retry the import with `no enable (gbl-ns-vol-shr)` followed by `enable`. (Use [show reports type Imp](#) to list all import reports.)

If a directory collides with a file, attribute synchronization is not enough to resolve the conflict. The managed volume must rename the directory (see [import rename-directories](#)) or the share import fails.

The `no` form of the command causes one of two reactions to a directory collision:

- rename the directory (if `import rename-directories` is set for this share) or
- fail the import (if `no import rename-directories` is set).

---

◆ **Note**

*For heterogeneous multi-protocol namespaces, always enable synchronization with the `import sync-attributes` command. Both CIFS and NFS attributes are compared in multi-protocol namespaces, greatly increasing the likelihood of directory collisions.*

**Guidelines (Cont.)** If the import fails, you can use [remove-share nomigrate](#) to remove the share from the managed volume. After the share is removed, you can fix the collisions directly on the filer and then re-import the share into the volume.

This option is particularly important for CIFS-subshare support, and is very helpful for Access-Based Enumeration (ABE). These synchronize directory-attribute settings, such as subshare ACLs and ABE settings, between the volume's filers. You can use the [filer-subshares](#) command to set up subshares for the current volume. Use the [cifs access-based-enum](#) command to set up ABE.

To change the rules for modifying files in this share, you can use the [import rename-files](#) command.

**Samples** `bstnA(gbl-ns-vol-shr[ns1~/vol~shr4])# import sync-attributes`  
allows the volume to synchronize directory attributes in the 'shr4' share.

`bstnA(gbl-ns-vol-shr[wwmed~/acct~bills])# no import sync-attributes`  
prevents the '/acct' volume from synchronizing directory attributes in the 'bills' share.

[import rename-files](#)

## managed-volume

- Purpose** Use the `managed-volume` command to assign a local, managed volume as the “back-end filer” for the current share. This only applies to shares in direct volumes. Use the `no` form of the command to remove the managed volume from the share.
- Mode** `gbl-ns-vol-shr`
- Security Role(s)** `storage-engineer` or `crypto-officer`
- Syntax** `managed-volume namespace volume [access-list list-name]`  
`no managed-volume`
- name* (1-30 characters) is the managed volume’s namespace.  
*volume* (1-1024 characters) identifies the managed volume.  
*list-name* (optional, 1-64 characters) is the NFS-access list to associate with the share.
- Default(s)** None.
- Guidelines** A `direct` volume has the option to use a managed volume to stand in as a *virtual filer* for one of its shares. The `managed-volume` command is analogous to the `filer` command, which assigns an external-filer share to the current namespace share. Before you use this command in an NFS volume, you must disable the managed-volume’s `auto reserve files` feature. A direct volume requires that any NFS share has a static, unchanging limit on its number of files. If the direct volume supports CIFS, the volume that you use as a virtual filer must be in the same namespace.
- Sample**

```
bstnA(gbl-ns-vol-shr[medco~/vol~sales])# managed-volume wwmed22 /04accts
```

 assigns the ‘wwmed22~/04accts’ managed volume as the filer for the ‘sales’ share.
- Related Commands** `namespace` -> `volume` -> `share`  
`direct`  
`filer`  
`no auto reserve files`

---

# max-volume-groups

**Purpose** Each ARX volume shares its memory, CPU time, and other resources with the other volumes in its *volume group*. On the ARX-500, memory and CPU cycles are less plentiful; the maximum volume groups are therefore set at a lower value on that platform. Raising the number of volume groups could create a resource-contention issue on an ARX-500. On the advice of F5 Support, you can use the `max-volume-groups` command to raise the maximum to the upper limit.

Use the `no` form of the command to return to the default maximum for volume groups.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `max-volume-groups`  
`no max-volume-groups`

**Default(s)** 2 volume groups

**Valid Platforms** ARX-500

**Guidelines** This command doubles the maximum volume groups. The default is sufficient for most installations. Use this command only under the guidance of F5 personnel.

You can only change this maximum while all volumes are disabled. Use `no enable` in `gbl-ns` mode to disable all volumes in a namespace (see the documentation for [enable \(gbl-ns, gbl-ns-vol\)](#)). You cannot reduce the number to a point where current volume-group assignment would be impossible; for example, if a volume is already assigned to volume-group 3, you cannot use `no max-volume-groups` because it would reduce the maximum to 2 groups.

Each volume group uses the memory set by the [metadata cache-size](#) command. The ACM processors require at least that much memory for each volume group. The [show processors](#) command shows the memory resident to each processor on your system.

Use the [volume-group](#) command to assign a volume to a group. The [show volume-group](#) command shows all volume-to-group assignments.

**Samples** `canbyA(gbl)# max-volume-groups`  
allows the maximum possible volume groups on the current switch, an ARX-500. This should only be done on the advice of F5 personnel.

`canbyA(gbl)# no max-volume-groups`  
resets the maximum number of volume groups back to the recommended default.

| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>       | <p>This command marks the volume's current metadata share as a critical resource. If the volume loses contact with its metadata share, the switch where the volume is running may fail over to the peer switch. (The failover occurs only if the peer switch has access to <i>all</i> of its critical resources.) Use the <code>show redundancy critical-services</code> command to see a list of all critical resources on this switch.</p> <p>The ARX tests for failure with a regular ICMP ping. Every 30 seconds, the ARX sends a ping to the metadata share's filer. If the filer fails to respond, the ARX waits an additional 30 seconds before asking the peer if it is possible to fail over. The pings continue indefinitely at 30-second intervals. If the filer responds before the failover is initiated, the failover does not occur.</p> <p>If this switch has a redundant peer, this is recommended for all volumes. This command is irrelevant unless redundancy is configured. See <a href="#">redundancy</a>.</p> |
| <b>Sample</b>           | <pre>bstnA(gbl-ns-vol[wwmed~/acct])# metadata critical</pre> <p>declares that the metadata share for <code>wwmed~/acct</code> is a critical resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

---

## metadata share

**Purpose** Use the `metadata share` command to make a dedicated metadata share available for the current managed volume, or for all managed volumes in the current namespace.  
Use the `no` form of the command to remove the metadata share from the current managed volume or namespace.

**Modes** gbl-ns  
gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `metadata share filer {nfs3|nfs3tcp|cifs} path [cluster cl-name]`  
`no metadata share filer {nfs3 | nfs3tcp | cifs} path`  
`[cluster cl-name]`

*filer* (1-64) is the name of an external filer; use [show external-filer](#) to list all of them.

`nfs3 | nfs3tcp | cifs` chooses the protocol for file-access. This can be outside the set of protocols for the namespace.

*path* (1-900 for NFS, 1-1024 for CIFS) is the share path on the filer (for example, `/arx_meta`).

*cl-name* (optional, 1-64 characters) is only relevant if the ARX is part of a disaster-recovery (DR) configuration. In a DR configuration, there is an active ARX cluster with one set of filers and a backup cluster with a mirrored set of filers. This determines which cluster uses the *filer*. Run the `metadata share` command twice per volume if you use DR: once to designate the metadata share's host at the active cluster, and again to determine the metadata host at the backup cluster. Use [show cluster](#) for a list of configured clusters. If you omit this option, the CLI applies the change to the local cluster.

**Default(s)** None

**Guidelines** A CIFS namespace can use a CIFS or NFS metadata-only share, but an NFS namespace is limited to metadata-only shares that also support NFS. An NFS namespace does not have the [proxy-user \(gbl-ns\)](#) credentials that it needs to access a CIFS metadata-only share.

If this switch has a redundant peer, use the `gbl-ns-vol metadata critical` command to declare the volume's metadata-only share as a critical resource.

If possible, use one metadata share per managed volume. Multiple managed volumes and/or namespaces can use the same metadata-only share, but this is not recommended.

A metadata share should reside on an extremely fast and reliable filer. Ideally, it should reside in its own file system on the same filer where you store the ARX volume's Tier 1 shares. The `show statistics metadata` command shows the latency between the ARX and its metadata shares. You can use the `nsck ... migrate-metadata` command to migrate a volume's metadata to a new filer, even after the volume has imported all of its back-end shares. This takes the volume offline during the migration. It is a safe operation in that it reverts the volume back to its original metadata share if it is interrupted.

For the best volume performance, configure all NFS-metadata shares with the 'sync' and 'no\_wdelay' options. These options cause the back-end NFS service to synchronously write to disk without any caching, to improve both reliability and speed. You set these options at the back-end filer, in the configuration for the NFS export. This is not an issue with CIFS-metadata shares, which perform synchronous writes to disk on request.

Do not store your metadata on /vol/vol0 on a NetApp filer. This is where the NetApp filer keeps its operating system; it is not intended for fast access.

**Sample**

```
bstnA(gbl-ns[wwmed])# metadata share nas1 nfs3 /vol/vol1/meta1
sets a metadata-only share to hold all managed-volume metadata for the
"wwmed" namespace.
```

**Related Commands** [metadata critical](#)  
[show external-filer](#)  
[show global-config namespace](#)  
[nsck ... migrate-metadata](#)  
[show statistics metadata](#)

---

# modify

**Purpose** When a managed volume imports files, the import fails if there are any file collisions (that is, if the same file name and path exist on two or more shares). Further, clients cannot modify any files in the volume; the volume is read-only after the import. To allow managed-volume modifications, use the **modify** command.

Use the **no** form of the command to prevent all modifications to imported files.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **modify**  
**no modify**

**Default(s)** **no modify**

**Guidelines** This command does not apply to direct volumes (see [direct](#)); only metadata-based managed volumes.

The CLI prompts you with a question about **nsck rebuild**. The [nsck ... rebuild](#) command takes the volume offline and re-imports with a single command. Answer **yes** to turn **modify** on after a rebuild, or answer **no** to leave it off. A **no** answer makes the volume read-only after any re-import. If you answer **no**, you can use the [reimport-modify](#) command to achieve the same effect.

If the **modify** command is in effect when the volume is enabled, it renames collided files according to the following syntax:

```
pathname_share-jobid.ext
```

where

*pathname* is the original pathname minus any extension that the file may have had,

*share* is the name of the namespace share that imported the file,

*jobid* is a unique ID number for this import job, and

*ext* is the file's original extension.

Directories are only renamed if they have the same name as a previously-imported file, or if they have different file attributes (such as permissions settings) than an already-imported directory. A directory is renamed according to the same conventions as a file.

Whether or not you enabled modifications before import, each share's import report shows any and all duplicate files and directories in the share. Use [show reports](#) to get a list of import reports. Import reports are named

"import.*share-id.share-name.job-id.rpt*." Use [show reports \*import-report\*](#) to view the contents of an import report. Duplicate files and directories are each called out in a separate line starting with "Duplicate."

**Guidelines (Cont.)** If you enable a volume without `modify` enabled, clients cannot write to the volume. This creates an opportunity to check the import reports and resolve any file conflicts at your back-end filers. If there were no collisions, use the `modify` command to enable the volume for client writes. If there were collisions, correct them at the back-end and/or accept them. Then use the `nsck ... destage` command to take the volume offline, allow modifications with `modify`, then use `enable (gbl-ns-vol-shr)` on each of the volume's shares.

**Guidelines: A “no modify” Import** You can opt to test an import before committing it with a “no modify” import. This means importing to the managed volume with the `modify` flag down, then checking all of the import reports for collisions or other issues. Use `show reports type Imp` to list all import reports, and `show reports report-name` to read one.

If no issues occurred, you can use the `modify` command after the import to allow write access to clients.

**Guidelines: Per-Share Exceptions** You can protect certain shares in the managed volume from file and/or directory renaming. Use the `no import rename-files` command to disallow file renames in a particular share. Use `no import rename-directories` to disallow directory renames. To allow the volume to synchronize the attributes of matching directories instead of renaming them, use `import sync-attributes`; if the volume is allowed to synchronize attributes or rename directories, it synchronizes the directory attributes.

The above preference only applies to directories that collide with other directories. For a directory that collides with an already-imported file, the conflict cannot be resolved with an attribute change.

Shares in multi-protocol volumes have an additional import option for directories: `import rename-directories unmapped-unicode`. This allows the volume to rename directories whose names contain non-mappable characters; that is, multi-byte characters that are supported by CIFS but not by the setting for `character-encoding nfs`.

**Samples** `bstnA(gbl-ns-vol[wwmed~/acct])# modify`  
Automatically re-enable volume modify mode during nsck rebuild?  
[yes/no] **yes**  
allows the `wwmed~/acct` volume to modify its back-end shares.

`bstnA(gbl-ns-vol[ns1~/])# no modify`  
disallows modifications for the “/” volume in the “ns1” namespace.

**Related Commands** `namespace -> volume`  
`enable (gbl-ns-vol-shr)`  
`show reports`  
`nsck ... destage`  
`nsck ... rebuild`  
`reimport-modify`  
`import rename-files`  
`import rename-directories`  
`import sync-attributes`

---

# named-streams

**Purpose** A *named stream* (or *Alternate Data Stream*) is a hidden file with meta-information about the main file, such as a summary description or a thumb-nail graphic. If any back-end-CIFS filer does not support named streams, you must disable the feature for its namespace volume. This applies to volumes in namespaces that support CIFS, not in NFS-only namespaces. Use the `no named-streams` command to stop the volume from using named streams.

Use the affirmative form, `named-streams`, to reinstate named streams.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `no named-streams`  
`named-streams`

**Default(s)** The volume probes the filer behind its first-enabled share and uses the `named-streams` setting from there.

**Guidelines** The Windows Explorer application uses named streams for the **Properties** -> **Summary** information; a volume that does not support named streams may not be able to provide any information for the **Summary** tab. Similarly, a volume without named streams may not support thumb-nail views of its graphics files.

You cannot enable a share if its volume supports named streams and its back-end-CIFS filer does not. The enable operation fails with an error that lists all CIFS features that must be disabled, possibly including this one. Use the [enable \(gbl-ns, gbl-ns-vol\)](#) command to enable all shares in a new namespace, or use the [enable \(gbl-ns-vol-shr\)](#) command to enable a new share in an already-enabled namespace. Use the [enable \(gbl-ns-vol-shr\)](#) command to enable a share.

If you remove the share(s) or upgrade the back-end filer(s), you can reinstate this feature for the volume. See the [ARX CLI Maintenance Guide](#) for instructions on removing a share from a namespace.

You can use the [show exports](#) command to see all CIFS options for the share.

CIFS clients only see the results of this command if they connect *after* you invoke it.

**Guidelines:** This CIFS option, together with three others, determines the File-System type (NTFS or a FAT file system) that the managed volume advertises to its CIFS clients. Client applications may query the file-system type and use it to customize the way it presents files; for example, if the managed volume advertises that it is a FAT file system, a client application may show old-style file-access times for the volume's files.

**Advertised File-System Type**

The volume advertises one of three file-system types, depending on the CIFS options supported by its back-end shares:

- NTFS - if the volume supports [named-streams](#), [persistent-acls](#), [unicode-on-disk](#), and all of the volume's back-end shares preserve case in their file/directory names ("MyFile.txt" is *not* converted to "MYFILE.TXT").
- FAT32 - if the volume supports [unicode-on-disk](#) and case preservation, but not the others.
- FAT - if the volume supports none of the above options.

On the advice of F5 Support, you can use the [cifs file-system-name](#) command to manually set this file-system name.

**Samples** `bstnA(gbl-ns-vol[medarcv~/usr])# no named-streams`  
shuts off named streams for the "/usr" volume in the "medarcv" namespace.

`bstnA(gbl-ns-vol[ns1~/])# named-streams`  
reinstates named streams for the "/" volume in the "ns1" namespace.

**Related Commands** [namespace](#) -> [volume](#)  
[enable \(gbl-ns, gbl-ns-vol\)](#)  
[enable \(gbl-ns-vol-shr\)](#)  
[show exports](#)

---

## nfs-param

**Purpose** Use the `nfs-param` command to change the NFS read size or write size between the current volume and its back-end shares.

Use the `no` form of the command to revert to the default.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `nfs-param {rsize | wsize} {1024 | 2048 | 4096 | 8192 | 16384 | 32768 | 65536}`  
`no nfs-param {rsize | wsize}`

`rsize` | `wsize` determines if this is the NFS-read size or write size.

`1024` | ... `65536` is the size of reads or writes, in bytes.

**Default(s)** `8192`

**Guidelines** The `nfs-param` command sets the size of NFS reads or writes from a volume to its back-end shares.

This parameter applies only to volumes that support NFS. Confirm that all filers behind the volume can support the read and/or write size that you choose.

**Samples** `bstnA(gbl-ns-vol[wwmed~/acct])# nfs-param rsize 16384`  
`bstnA(gbl-ns-vol[wwmed~/acct])# nfs-param wsize 16384`  
 sets the same read and write sizes for the “`wwmed~/acct`” volume.

`bstnA(gbl-ns-vol[ns1~/])# no nfs-param rsize`  
 reverts to the default NFS-read size in “`ns1~/`”

**Related Commands** [namespace](#) -> [volume](#)

## persistent-acls

- Purpose** A volume with persistent Access-Control Lists (ACLs) can display the ACLs of its files and directories to its clients. If any of the volume's back-end-CIFS filers do not also support persistent ACLs, you must disable this feature for the volume. This applies to volumes in namespaces that support CIFS, not volumes in NFS-only namespaces. Use the `no persistent-acls` command to stop the volume from supporting persistent ACLs.
- Use the affirmative form, `persistent-acls`, to reinstate persistent ACLs.
- Mode** `gbl-ns-vol`
- Security Role(s)** `storage-engineer` or `crypto-officer`
- Syntax** `no persistent-acls`  
`persistent-acls`
- Default(s)** The volume probes the filer behind its first-enabled share and uses the `persistent-acls` setting from there.
- Guidelines** This is only recommended for volumes whose back-end filers all share this limitation. We do not recommend mixing shares that support ACLs with shares that cannot.
- This controls the CIFS-client view of ACLs in the volume. If a Windows client accesses the "Properties" for any of the volume's files or directories, the "Security" tab does not appear unless the volume has the `persistent-acls` setting.
- You cannot enable a share if its volume supports persistent ACLs and its back-end-CIFS filer does not. The enable operation fails with an error that lists all CIFS features that must be disabled, possibly including this one. Use the [enable \(gbl-ns-vol-shr\)](#) command to enable a share.
- A volume with `no persistent-acls` does not copy ACLs from one back-end share to another when it performs migrations. This applies to all migrations, including migrations between two filers that support persistent ACLs. This may be surprising in a volume backed by filers that cannot support ACLs and other filers that can support them. As stated above, we do not recommend mixing ACL-supporting filers with non-ACL-supporting filers behind the same managed volume.
- If you remove the share(s) or upgrade the back-end filer(s), you can reinstate this feature for the volume. See the [ARX CLI Maintenance Guide](#) for instructions on removing a share from a namespace.
- You can use the `show exports` command to see all CIFS options for the share, including persistent ACLs.

---

**Guidelines:** This CIFS option, together with three others, determines the File-System type (NTFS or a FAT file system) that the managed volume advertises to its CIFS clients. Client applications may query the file-system type and use it to customize the way it presents files; for example, if the managed volume advertises that it is a FAT file system, a client application may show old-style file-access times for the volume's files.

**Advertised File-System Type**

The volume advertises one of three file-system types, depending on the CIFS options supported by its back-end shares:

- NTFS - if the volume supports [named-streams](#), [persistent-acls](#), [unicode-on-disk](#), and all of the volume's back-end shares preserve case in their file/directory names ("MyFile.txt" is *not* converted to "MYFILE.TXT").
- FAT32 - if the volume supports [unicode-on-disk](#) and case preservation, but not the others.
- FAT - if the volume supports none of the above options.

On the advice of F5 Support, you can use the [cifs file-system-name](#) command to manually set this file-system name.

**Samples** `bstnA(gbl-ns-vol[medarcv~/usr])# no persistent-acls`  
shuts off persistent ACLs for the "/usr" volume in the "medarcv" namespace.

`bstnA(gbl-ns-vol[ns1~/])# persistent-acls`  
reinstates persistent ACLs for the "/" volume in the "ns1" namespace.

**Related Commands** [namespace](#) -> [volume](#)  
[enable \(gbl-ns-vol-shr\)](#)  
[show exports](#)

## reimport-modify

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | An <code>nsck ... destage</code> or <code>nsck ... rebuild</code> shuts off the volume's <code>modify</code> setting as it takes the volume offline. The <code>modify</code> flag stays down when the shares reimport, so the volume does not modify any re-imported files <i>and</i> clients cannot modify the volume. To keep the <code>modify</code> flag up during a re-import, use the <code>reimport-modify</code> command. Use the <code>no</code> form of the command to prevent all modifications to re-imported shares.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Guidelines</b>       | <p>This command does not apply to direct volumes (see <a href="#">direct</a>); only metadata-based managed volumes.</p> <p>Raise this flag <i>before</i> you use <code>nsck</code> to rebuild or otherwise take the volume offline. The flag is only effective for future rebuilds.</p> <p>The CLI prompts for confirmation before raising the flag; answer <b>yes</b> to continue.</p> <p>The <code>modify</code> command determines whether or not modifications occur; this command determines whether or not to re-instate the volume's <code>modify</code> status after the volume is taken offline. This is an extra security measure to ensure that the system avoids any unexpected file renames.</p> <p>When you invoke the <code>modify</code> command, a prompt requests whether or not you want to set this flag at the same time.</p> <p>Whether or not you enabled modifications before import, each share's import report shows any and all duplicate files and directories in the share. Use <a href="#">show reports</a> to get a list of import reports. Import reports are named "import.<i>share-id.share-name.job-id.rpt</i>." Use <code>show reports import-report</code> to view the contents of an import report. Duplicate files and directories are each called out in a separate line starting with "Duplicate."</p> |

# replica-snap

**Purpose** You can designate a managed-volume share as a repository for snapshots, where the back-end filer behind the share holds snapshots from another share in the volume. You can use filer-replication methods to duplicate the files and directories from one filer to another, and you can take snapshots at the second filer without using disk space on the first. Use the `replica-snap` command to indicate that the current share is dedicated to snapshot storage in this way. This indicates that the managed volume should only present the back-end share's snapshots, and ignore any non-snapshot data. The managed volume's clients can then access these snapshots and restore previous versions of their files as needed.

Use the `no replica-snap` command to change the current share to a standard client-data share.

**Mode** `gbl-ns-vol-shr`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `replica-snap`  
`no replica-snap`

**Default(s)** `no replica-snap`

**Guidelines** This command has no effect in a `direct` volume.

You can only run this command when the share is disabled (`no enable (gbl-ns-vol-shr)`). If the managed volume has already imported the share's primary storage, you must destage the volume to use the share (see `nsck ... destage`). Typically, the command is applied to new shares.

You cannot use `no replica-snap` after the share is enabled, but you can use `no share` to remove a replica-snap share. This removes all of the share's snapshots from client view.

After you designate the share as a replica-snap share, you create a replica-snap-rule to create managed snapshots on it. You can use the `gbl-ns-vol snapshot replica-snap-rule` command to create this rule. As mentioned above, clients see the snapshots from this share instead of the share's files and directories, and access those snapshots through their usual method (such as the "Previous Versions" tab). To present any snapshots created previously, you can use the `snapshot manage` command.

## ◆ Important

---

*The managed volume cannot write to most replica-snap shares, so it cannot check a replica-snap share to see if another ARX owns it (see the documentation for `enable (gbl-ns-vol-shr) ... take-ownership`). Do not use the same replica-snap share behind two different ARXes, unless they are a redundant pair.*

**Guidelines (Cont.)** If your managed volume uses tiered storage where recently-changed files reside on tier-1 shares and unchanged files reside on tier 2, we recommend one or more replica-snap shares per tier-1 share. The tier-2 shares have files that are unchanged, so they do not require snapshots. (You can use the [place-rule](#) command to configure tiered storage.)

**Guidelines: Some Filer-Replication Applications Overwrite ARX Snapshots** Some filer-replication applications are volume-level, and copy the entire contents of the back-end share to the replica-snap share, including the filer snapshots. This would overwrite any snapshots that the ARX takes at the replica-snap share, and defeat the [snapshot replica-snap-rule](#). Do not use volume-level replication to copy the source share's contents to the replica-snap share.

**Guidelines: Filer Latency** Slow responses from a replica-snap share may cause slow responses for client access to files, too. The filer host for your replica-snap shares should not have an excessively long file-access latency.

**Samples** `bstnA(gbl-ns-vol-shr[medarcv~/lab_equipment~equipSnap])# replica-snap`  
designates the "equipSnap" share as a replica-snap share. The managed volume only presents snapshots from this share to its clients.

`bstnA(gbl-ns-vol-shr[ns1~/vol~shr6])# no replica-snap`  
resets the 'shr6' share to be a standard file-storage share.

**Related Commands** [namespace](#) -> [volume](#) -> [share](#)  
[enable \(gbl-ns-vol-shr\)](#)  
[snapshot replica-snap-rule](#)  
[snapshot manage](#)  
[nsck ... destage](#)

---

## reserve files

**Purpose** A managed volume requires one *file credit* for each of its files and directories. By default, the volume automatically increases its file credits as its number of files increases, but there are rare circumstances where you must manually set a volume's file credits. After you turn off [auto reserve files](#) for such a volume, you can use the `reserve files` command to manually set its file credits.

You can also use this command with auto-reserve enabled, though the auto-reserve feature may later change the number of reserved files.

Use the `no` form of the command to revert to a static default for the managed volume.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `reserve files files`  
`no reserve files`

*files* (4,096 to 128,000,000 (ARX-500) or to 256M (all other platforms)) is the new number of files to reserve for the volume. The maximums on your chassis may be lower due to your software license; use [show active-license](#) to see the limits imposed by your software license.

**Default(s)** 4,000,000 (4M) files if [auto reserve files](#) is set  
 64M files if `no auto reserve files` is set

**Guidelines** Each file and directory in a managed volume (as opposed to a [direct](#) volume) uses one *file credit*. By default, the managed volume automatically takes more file credits as it grows. This automatic growth is the [auto reserve files](#) feature. The `reserve files` command sets the *current* number of reserved files if the auto-reserve feature is enabled; the auto reserve feature may then increase the number of file credits from there.

This command is more effective in a volume where you must turn off the auto-reserve feature; it sets a permanent file-credit reservation in this case. You must disable the feature (with `no auto reserve files`) in a volume used as a “filer” by an NFS-supporting [direct](#) volume. The documentation for [auto reserve files](#) discusses this further.

Each volume group supports a maximum of 384 Million (M) file credits. The ARX-500 can support 2 volume groups, and the ARX-2000 supports 12. The ARX-4000 supports 16 volume groups, but each volume group on the ARX-4000 supports a lower maximum (256M). This is the ceiling for the sum of all reserved files for all volumes in the volume group. You can use the [show volume-group](#) command to list the current number of reserved files for each volume; see the [File credits](#) section of the output.

**Sample** `bstnA(gbl-ns-vol[archives~/multimedia])# reserve files 5000000`  
 reserves 5000000 files for the '/multimedia' volume.

**Related Commands** [namespace](#) -> [volume](#)  
[auto reserve files](#)  
[show volume-group](#)

## restart namespace ... volume

**Purpose** Use the `restart namespace ... volume` command to restart processing in a specific volume. This also restarts all other volumes that run in the same volume group.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `restart namespace name volume volume [dump-core]`

*name* (1-30 characters) identifies the namespace.

*volume* (1-1024 characters) is the volume to restart. All volumes in the same volume group will also restart. Use to [show volume-group](#) see the assignments of volumes to volume groups.

**dump-core** (optional) causes the namespace process to write out its memory contents in a core-memory file. F5 personnel can examine this core file to diagnose problems with the namespace. This slows the restart; use this option only on the advice of F5 personnel.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before restarting the namespace volume(s). If any front-end services export any of the affected volumes, the prompt lists the services. Enter **yes** to proceed.

This restarts all of the volumes in the chosen volume's group. A *volume group* can fail over from one chassis to another in a redundant configuration. It is also a failure domain for a group of volumes in the same namespace; if one of the volumes restarts, they all restart together. Use the [show volume-group](#) command to show all volume groups and their volumes. Before a volume is enabled, you can use [volume-group](#) to assign it to a group.

**Sample** `bstnA# restart namespace wwmed volume /acct`

The Volume Group hosting namespace 'wwmed', volume '/acct' is in use by NFS global service 'ac1.medarch.org'.

These services will experience a brief outage as the Volume Group hosting the namespace 'wwmed', volume '/acct' is restarted.

Do you wish to proceed? [yes/no] **yes**

restarts the "wwmed~/acct" volume, along with any other volumes in its volume group.

**Related Commands** [show volume-group](#)  
[volume-group](#)

---

# share

**Purpose** Use the `no` form of the command to delete a managed-volume share.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `share name`  
*name* (1-64 characters) is the name you choose for the share.

`no share name`

`no share name relocate-dirs target-share [remove-file-entries [verbose] [offline]]`

*name* (1-64 characters) identifies the share to remove.

**relocate-dirs** is required if you are removing an already-imported share from a managed volume. This is never required in a direct volume or a [replica-snap](#) share.

**target-share** (1-64 characters) is another share in the same managed volume. The volume migrates all master directories in the current share to this target.

You can enter the optional flags (**remove-file-entries**, **offline**, and **verbose**) in any order. As above, these options only apply to managed volumes and never apply to [replica-snap](#) shares:

**remove-file-entries** removes all files from volume metadata that still reside on this back-end share.

**verbose** (optional, if you choose **remove-file-entries**) causes the operation to list all removed files in its “removeShare” report.

**offline** (optional, if you choose **remove-file-entries**) is only for back-end shares that are offline or otherwise unreachable. This forces the disconnect without scanning the back-end for its directory attributes. Relocated master directories therefore have all of their file attributes set to 0 (zero).

**Default(s)** None

**Guidelines** A *share* maps to a CIFS share or NFS export on back-end storage. Use the `share` command to add a share in a managed volume or a direct volume (see [direct](#)).  
The CLI prompts for confirmation before creating a new share; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new objects.) This places you in `gbl-ns-vol-shr` mode, where you must use the `filer` command to identify a filer and export/share, and then use the [enable \(gbl-ns-vol-shr\)](#) command to import the export/share. In a direct volume, you also use the `attach` command to map one or more attach-point directories in the share to physical directories on the back-end filer.

**Guidelines: no share** You can remove the share with the simple `no share` command before it is first imported. There is no import for a share in a direct volume or for a [replica-snap](#) share, so you can use this simple form any time in those cases.

After a managed-volume share has been imported, you can use a [place-rule](#) to migrate all of its files to other shares in the volume. If the volume supports snapshots (with a [snapshot rule](#), [notification rule](#), or similar rule), we recommend waiting until all retained snapshots have “aged out” before removing the volume. After the last of the current snapshots is gone, none of the snapshots on this share have any record of any files in the volume. At that point, you can safely remove the share.

After the files (and, possibly, snapshots) are cleared, you use the `relocate-dirs` argument in `no share` to relocate the share’s master directories, too. (A volume typically has multiple copies of its directories in each share, so that it can migrate files between them; a *master directory* is the first-imported (or only) instance of a directory in a volume.) The volume scans the back-end share for the file attributes of these directories, to be duplicated at the *target-share*. If this is impossible because the back-end share is offline, use the `offline` flag (along with the `remove-file-entries` flag) to create new instances of the directories with zeroed-out file attributes.

The CLI creates a “removeShare” report to show the progress of the `no share` command. Each report is named “removeShare.*share-name*.rpt,” where *share-name* is the ARX-share name (not the name of the share at the filer).

The `no share` command fails if any of the client-visible files in the volume are on the share; the `remove-file-entries` flag removes the files from the volume metadata and allows the `no share` operation to succeed. The number of files removed appears in the removeShare report. The additional `verbose` flag adds the names of each removed file into the report. The additional `offline` flag, described above, applies to unreachable filers.

As an alternative to `no share` in a managed volume, you can use [remove-share migrate](#) to remove an imported managed-volume share, [remove-share nomigrate](#) to remove a managed-volume share that failed to import, or [remove-share offline](#) to remove a share that is unreachable.

**Samples** `bstnA(gbl-ns-vol[archives~/multimedia])# share lun77`  
This will create a new share.

```
Create share 'lun77'? [yes/no] yes
bstnA(gbl-ns-vol-shr[archives~/multimedia~lun77])#
 creates a share named “lun77” in the current managed volume.
```

```
bstnA(gbl-ns-vol[archives~/multimedia])# no share nas15
 deletes the “nas15” share from the volume.
```

```
bstnA(gbl-ns-vol[ns1~/])# no share test relocate-dirs share4
 removes the “test” share, migrating all of its master directories to “share4” in the
 “ns1~/” volume.
```

## show share status

- Purpose** Use the `show share status` command to view the current status of all namespace shares on the ARX.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show share status`
- Guidelines** The output contains a small table for every volume on the ARX. This information is an summary of the data from [show namespace](#).
- Each volume starts with a single-line summary. The summary contains the following fields:
- NS identifies the namespace.
  - Vol is the path name of the volume.
  - MD is a high-level status of the volume's [metadata share](#). This appears in *used/free* format, where *used* is the amount of space used for the volume's metadata, and *free* is the space remaining on the metadata share. You can ignore these numbers for a [direct](#) volume, which does not use a metadata share.
  - I/VG is the volume's *Instance ID* (used internally) and [volume-group](#) number, separated by a slash (/).
  - Files shows the number of files used and free, along with the maximum file allowable in volume. The maximum is labeled "(automatic)" for a volume with [auto reserve files](#) enabled.
- Below each summary line is a table of the volume's shares, one row for each share. Each row contains two fields:
- Share Name** is the name established by the [share](#) command.
  - Status** is the same share status documented for the [show namespace](#) command (see [Guidelines: Share-Import Status](#), on page 21-36, [Guidelines: Disable/Removal Status](#), on page 21-37, and [Table 21.1 on page 21-49](#)). You can use this to watch the progress of a share import.
- Sample** `bstnA# show share status`  
shows the share status for all configured volumes. For sample output, see [Figure 22.4 on page 22-84](#).
- Related Commands** [show namespace status](#)  
[show namespace](#)

## show sid-translation

**Purpose** Use the `show sid-translation` command to view the translation of a user or group name to a numeric security ID (SID), or from SID to name. This shows the translation for every share in the current volume.

**Mode** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `show sid-translation {user | group | sid}`

*user | group | sid* chooses the entity to translate:

*user* (1-256 characters) is a Windows user name.

*group* (1-256 characters) is a Windows group name.

*sid* (1-256 characters) is a numeric SID; this does a reverse translation to the corresponding user or group name.

**Guidelines** This command does not apply to an NFS-only namespace.

The output shows the SID-to-name translation from each share in the current volume:

**Share** is the name of the namespace share.

**SID** is the globally-unique ID to identify the principal (user or group) below.

**Name** is the name of the requested user, group, or SID. In parenthesis is the type of this principal: “user,” “group,” “domain,” “alias” (a locally-defined principal), “well-known group” (such as “everyone”), “deleted account,” “invalid,” or “unknown.”

If any of the shares have unique translations, some or all of the shares are configured for Local Groups. If the volume migrates a file to or from a share with Local Groups, the volume must translate the SID to a name on the source share and then translate it back on the destination share.

For any share whose filer uses Local Groups, use the `gbl-ns-vol-shr sid-translation` command to tell the volume to translate all of its SIDs.

**Sample** `bstnA(gbl-ns-vol[medarchv~/rcrds])# show sid-translation jqpublic`  
SID Translations:

```
Share rx
 SID: S-1-5-21-448539723-1844237615-725345543-1217
 Name: MEDARCH\jqpublic (user)
```

```
Share charts
 SID: S-1-5-21-448539723-1844237615-725345543-1217
 Name: MEDARCH\jqpublic (user)
```

```
Share bulk
 SID: S-1-5-21-448539723-1844237615-725345543-1217
 Name: MEDARCH\jqpublic (user)
```

**Related Commands** `namespace` -> `volume` -> `share`  
`sid-translation`

---

# show volume-group

**Purpose** A volume is permanently assigned to a *volume group* when it is enabled. The volume group shares a memory pool as well as CPU cycles and other resources. Use the `show volume-group` command to view the current volume-group assignments.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show volume-group [id] [detailed] [legacy]`

*id* (optional, 1-255) identifies a particular volume group. If you omit the number, this command displays all volume groups.

**detailed** (optional) adds details to the output: the current CPU and memory usage for each processor behind the volume group.

**legacy** (optional) presents the same output using terminology from former ARX releases, where volume groups were called “VPU domains,” and there were two or more of them in each “VPU.”

**Guidelines** This applies to the current switch only, not both switches in a redundant pair. To see the volume groups in the redundant peer, log into that peer and run the command from its CLI.

System Credits is a table of system-wide limits for the ARX:

Share credits lists the number of shares configured in the system, share credits remaining, and the total number of shares allowed. These are managed-volume shares, not direct-volume shares.

Direct Share credits lists the number of direct shares in the system, direct-share credits remaining in this ARX, and the total number of direct shares allowed in the ARX. Direct shares are the shares in a direct volume; a direct volume is declared with the `direct` command.

Volume credits lists the number of volumes currently in the system, volume credits remaining, and the total number of volumes allowed.

File credits lists the number of files currently in the system, file credits remaining, and the total number of files allowed. These credits only apply to a to the managed volumes on the system. A volume automatically sets its file-credit reservation if it has `auto reserve files` enabled. You can manually set the number of file credits with the `reserve files` command.

The “*n* credits remain” is not a guarantee for any given volume in the system. Other volumes in other volume groups draw from the same pool of file credits. If the system’s file credits are sufficiently low, all volumes in the system share the same credits; if volume A uses 100 file credits, volumes B and C each lose 100 remaining credits, too.

**Guidelines (Cont.)** Volume Group *n* is a table to describe one of the volume groups on this system. One of these tables appears per volume group:

**Physical Processor** shows the actual CPU where the volume group is running. If you used the **detailed** keyword, this also shows current CPU and memory usage.

**State** is one of the following:

- **off** means that there is no physical CPU to back this volume group.
- **empty** means that there are no volumes assigned to the group.
- **Normal** indicates that there is room for more namespaces or volumes on this volume group. If credits have run out for one or more of these categories, one or more qualifiers appears here:
  - **partially used** indicates there is room for at least one more volume.
  - **maximum instances** means that you can add no more volume groups to the namespace. Both volume groups have a namespace assigned to them.
  - **maximum volume capacity** means that you cannot add any more volumes to the group.
- **Degraded** means that too many volume groups are sharing the same memory and processor resources. This only occurs after a failover between redundant peers.
- **Unrunnable** is very rare. This appears only if multiple hardware failures reduce the hardware resources to the level where there is not enough memory and/or CPU cycles to continue running the current volume group.
- **Error** is an unexpected error; please contact Customer Support if you see this.

**Share credits** lists the number of managed-volume shares configured in the volume group, share credits remaining, and the total number of shares allowed.

**Direct Share credits** lists the number of direct shares in the volume group, direct-share credits remaining, and the total number of direct shares allowed in the volume group. Direct shares are the shares in a direct volume; a direct volume is declared with the **direct** command.

**Volume credits** lists the number of volumes currently in the volume group, volume credits remaining, and the total number of volumes allowed.

**File credits** lists the number of files currently in the volume group, file credits remaining, and the total number of files allowed. These credits only apply to the managed volumes on the system. A volume automatically sets its file-credit reservation if it has **auto reserve files** enabled. You can manually set the number of file credits with the **reserve files** command.

Then there is a table of namespaces and volumes assigned to the volume group, showing the state of each volume. If you select the legacy option, an additional column shows the VPU and VPU-domain number of the volume group; these are offered for users of former ARX releases that used this terminology.

Use the **volume-group** command to assign a volume to a group. Use the **nsck ... migrate-volume** command to re-assign a volume from one group to another.

**Samples** `bstnA# show volume-group`  
shows all volume groups on the system. See [Figure 22.5 on page 22-89](#).

`bstnA# show volume-group 1`  
focuses on volume group 1. See [Figure 22.6 on page 22-90](#).

`stkgbrgA# show volume-group 1 detailed`  
shows volume group 1 on another chassis, with CPU and memory usage. See [Figure 22.7 on page 22-91](#).

## sid-translation

**Purpose** One or more of your back-end CIFS filers may be configured for *Local Groups* and users. These filers use local Security IDs (SIDs) for their group/user names instead of those issued by the Domain Controller (DC). To migrate a file to or from a share with Local Groups, the volume must translate the group SIDs in the file's Access Control List (ACL). Use the `sid-translation` command to enable SID translation for the current share.

To disable SID translation for this share, use `no sid-translation`.

**Mode** `gbl-ns-vol-shr`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `sid-translation`  
`no sid-translation`

**Default(s)** `no sid-translation`

**Guidelines** This command does not apply to an NFS-only namespace.

Whenever the volume migrates a file to or from a share tagged for SID translation, it translates each SID to a group name (at the source share), then translates the group name back to a SID (at the destination share). This ensures that the final SID is one that is properly configured at the destination filer.

All filers behind the volume should support all of each other's local-group names. If a file tagged with local-group name, "staff", migrates to another filer without any definition for a "staff" group, the volume copies the group SID without translating it. The SID is invalid on the filer, though it will be valid if it migrates back later. While the file remains on that filer, all Access Control Entries (ACEs) using that SID are ignored. To avoid these translation failures, duplicate all local group names and user names on all of the filers behind the volume.

Some filers return SID errors for unknown SIDs. This can occur if SID translation fails, due to one filer lacking a local-group or local-user name that is present on the other filers. By default, the policy engine cancels the migration if it receives a SID-translation error. Some file servers (for example, EMC Celerra servers) return errors for unknown SIDs but accept the file or directory anyway. You can use the [ignore-sid-errors](#) command to ignore the SID errors from these file servers.

Use the `gbl-ns-vol show sid-translation` command to translate SIDs to names or names to SIDs for every share in the volume.

**Samples** `bstnA(gbl-ns-vol-shr[medarcv~/rcrds~bulk])# sid-translation`  
causes the volume to translate SIDs for all files migrated to the "bulk" share.

`bstnA(gbl-ns-vol-shr[insur~/claims~shr1-next])# sid-translation`  
causes the volume to translate SIDs for all files migrated to the "shr1-next" share.

## sparse-files

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Some applications create “holes” in files with no data (that is, all zeros); a volume that supports <i>sparse files</i> like these does not use any disk space for those holes. If any back-end-CIFS filer does not support sparse files, you must disable the feature for its namespace volume. This applies to volumes in namespaces that support CIFS, not in NFS-only namespaces. Use the <b>no sparse-files</b> command to stop the volume from using sparse files.<br><br>Use the affirmative form, <b>sparse-files</b> , to reinstate sparse files.                                                                                                                                                                                                                                               |
| <b>Mode</b>             | gbl-ns-vol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Syntax</b>           | <b>no sparse-files</b><br><b>sparse-files</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Purpose</b>                                         | <p>A volume that supports <i>unicode</i> on disk can support file names with any of the multi-byte characters (such as Korean or Japanese characters) supported by the Unicode character set. If any back-end-CIFS filer does not support Unicode file names on disk, you must disable the feature for its namespace volume. This applies to volumes in namespaces that support CIFS, not in NFS-only namespaces. Use the <code>no unicode-on-disk</code> command to stop the volume from using Unicode file names on disk.</p> <p>Use the affirmative form, <code>unicode-on-disk</code>, to reinstate Unicode file names on disk.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Security Role(s)</b>                                | <code>storage-engineer</code> or <code>crypto-officer</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>                                          | <code>no unicode-on-disk</code><br><code>unicode-on-disk</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Default(s)</b>                                      | The volume probes the filer behind its first-enabled share and uses the <code>unicode-on-disk</code> setting from there.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Guidelines</b>                                      | <p>A Windows client cannot use multi-byte Unicode characters in any file or directory names unless the volume supports unicode on disk.</p> <p>You cannot enable a share if it supports Unicode file names on disk and its back-end-CIFS filer does not. The enable operation fails with an error that lists all CIFS features that must be disabled, possibly including this one. Use the <a href="#">enable (gbl-ns-vol-shr)</a> command to enable a share.</p> <p>If you remove the share(s) or upgrade the back-end filer(s), you can reinstate this feature for the volume. See the <a href="#">ARX CLI Maintenance Guide</a> for instructions on removing a share from a namespace.</p> <p>You can use the <a href="#">show exports</a> command to see all CIFS options for the share.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Guidelines:<br/>Advertised<br/>File-System Type</b> | <p>This CIFS option, together with three others, determines the File-System type (NTFS or a FAT file system) that the managed volume advertises to its CIFS clients. Client applications may query the file-system type and use it to customize the way it presents files; for example, if the managed volume advertises that it is a FAT file system, a client application may show old-style file-access times for the volume's files.</p> <p>The volume advertises one of three file-system types, depending on the CIFS options supported by its back-end shares:</p> <ul style="list-style-type: none"><li>• NTFS - if the volume supports <a href="#">named-streams</a>, <a href="#">persistent-acls</a>, <a href="#">unicode-on-disk</a>, and all of the volume's back-end shares preserve case in their file/directory names ("MyFile.txt" is <i>not</i> converted to "MYFILE.TXT").</li><li>• FAT32 - if the volume supports <a href="#">unicode-on-disk</a> and case preservation, but not the others.</li><li>• FAT - if the volume supports none of the above options.</li></ul> <p>On the advice of F5 Support, you can use the <a href="#">cifs file-system-name</a> command to manually set this file-system name.</p> |

---

**Samples** `bstnA(gbl-ns-vol[medarcv~/usr])# no unicode-on-disk`  
shuts off Unicode file names on disk for the “/usr” volume in the “medarcv” namespace.

`bstnA(gbl-ns-vol[ns1~/])# unicode-on-disk`  
reinstates Unicode file names on disk for the “/” volume in the “ns1” namespace.

**Related Commands** [namespace](#) -> [volume](#)  
[enable \(gbl-ns-vol-shr\)](#)  
[show exports](#)

# volume

**Purpose** Use the **volume** command to create a new volume or edit an existing one. A volume appears to clients as a discrete file system in the namespace. If it is a managed volume, it contains imported shares from various back-end filers. A direct volume contains attach points to the filers behind it.

Use the **no** form of the command to delete a volume.

**Mode** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **volume** *path*  
**no volume** *path*

*path* (1-256 characters) is a directory path you choose for the managed volume (for example, “/multimedia”). This is the root directory for the managed volume.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before creating a new volume; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new objects.)

This places you in gbl-ns-vol mode, from which you include one or more exports or shares from back-end filers. From gbl-ns-vol mode, you must use the [share](#) command to create at least one share in the current volume; each share connects to one export/share from a back-end filer.

The remaining configuration options are dependant on the type of volume you are configuring. A *managed volume* imports the files and directories from its shares, manages metadata for all of them, and supports policies that migrate the files. A *direct volume* has virtual subpaths that attach to directories on the filer; this does not manage metadata or support any policy.

**Guidelines: Managed Volumes** In a managed volume, the files are imported from each filer export/share to the root *path* of the managed volume. A file in the root of the imported export/share also appears in the root of the managed volume. This introduces the possibility of naming collisions. If your first filer share has a file named “myFile.txt” in its root, you cannot import another filer share to the same managed volume if it also has a “myFile.txt” file in its root. Optionally, you can allow the volume to rename the second file: use the [modify](#) command to do this.

A managed volume offers the option to group the shares into share farms; you can then apply capacity-balancing policies to each share farm. Use the [share \(gbl-ns-vol-sfarm\)](#) command to create a share farm in the current managed volume.

**Guidelines: Direct Volumes** In a direct volume, the *path* is a read-only directory that contains the volume’s *attach points*. Each attach point is a directory that directly connects a client to a back-end share. Use the [direct](#) command to make a volume into a direct volume. After you create a share with the [share](#) command, use [attach](#) to attach a directory from the volume to a back-end filer.

---

**Guidelines:** To prepare for removing a volume, all of the volume's contents must be removed first. That is, it must be deactivated ([nsck ... destage](#)), it can contain no rules (various commands), share farms (no [share-farm](#)), filesets (various commands), or shares (use [remove-share migrate](#) or no [share](#)). Additionally, no front-end service can be exporting the volume (no [cifs](#) or no [nfs](#)), and no CIFS service for this namespace can have [browsing](#) enabled. (You can work around this problem by disabling the volume with no [enable \(gbl-ns, gbl-ns-vol\)](#)).

The [remove namespace ... volume](#) command performs all of the above steps for you. Best practices dictate that you use that command instead.

**Samples** `bstnA(gbl-ns[archives])# volume /multimedia`  
This will create a new volume.

```
Create volume '/multimedia'? [yes/no] yes
bstnA(gbl-ns-vol[archives~/multimedia])#
 creates a managed volume at /multimedia.
```

```
bstnA(gbl-ns[archives])# no volume /radio
 deletes the "/radio" volume.
```

## volume-group

**Purpose** A *volume group* shares a single memory pool along with CPU-processing time and other resources. If certain catastrophic failures cause a single volume to fail, they can stop processing for all other volumes in the same group. You should therefore group your volumes carefully, to insulate volumes from one another as needed. Use the `volume-group` command to explicitly choose the volume's group rather than allowing a default assignment.

Use `no volume-group` to allow default-group assignment.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `volume-group id`  
`no volume-group`

*id* is the group ID you assign to the current volume. All the volumes in a given group must belong to the same namespace. On an installation with many volumes in a small number of namespaces, you have the option to divide each namespace's volumes among multiple volume groups.

On the ARX-500 you are limited to half of your potential volume groups. This ensures that the volume software has enough memory to function in most cases, but it reduces the potential number of failure domains that you can use. On those platforms, you can increase the maximum number of volume groups with [max-volume-groups](#).

**Default(s)** Internal software chooses a default volume-group assignment for each volume. We recommend choosing volume groups explicitly with this command or [nsck ... migrate-volume](#) instead of using the default.

**Guidelines** On every platform except the ARX-2000 or ARX-4000, each volume group can hold up to 64 volumes. An ARX-2000 volume group can hold up to 48 volumes, and an ARX-4000 volume group can hold up to 32 volumes.

The namespace software assigns a volume to its group when the volume is enabled (see [enable \(gbl-ns, gbl-ns-vol\)](#)). If necessary, you can use the [nsck ... migrate-volume](#) command to change the volume-group assignment after the volume is enabled. Use the [show volume-group](#) command to view the current volume-group assignments on the current switch.

It is possible for default volume-group assignments to artificially limit the maximum number of namespaces on your system. Use this command to make explicit volume-group assignments before the volumes are enabled.

**Guidelines: Splitting a Namespace**

If a volume has a catastrophic metadata failure (such as losing contact with the back-end filer), all other volumes in the same volume group become unusable. To mitigate this potential problem, you can divide a namespace's volumes into multiple independent groups. If one volume has a catastrophic failure in one group, volumes in the other group(s) are unaffected.

On the ARX-500 you are limited to half of your potential volume groups. This ensures that the volume software has enough memory to function in most cases, but it reduces the potential number of failure domains that you can use. On those platforms, you can increase the maximum number of volume groups with [max-volume-groups](#). The number of volume groups affects the memory usage for volume processing (see [metadata cache-size](#)), so you should only change this on the advice of F5 personnel.

**Samples**

```
bstnA(gbl-ns[archives])# volume /multimedia
bstnA(gbl-ns-vol[archives~/multimedia])# volume-group 1
bstnA(gbl-ns-vol[archives~/multimedia])# exit
bstnA(gbl-ns[archives])# volume /radio
bstnA(gbl-ns-vol[archives~/radio])# volume-group 1
bstnA(gbl-ns-vol[archives~/radio])# ...
```

assigns two volumes to volume group 1. That volume group is now dedicated to volumes from the "archives" namespace.

```
bstnA(gbl-ns[ns3])# volume /vol1
bstnA(gbl-ns-vol[ns3~/vol1])# volume-group 2
bstnA(gbl-ns-vol[ns3~/vol1])# exit
bstnA(gbl-ns[ns3])# volume /vol2
bstnA(gbl-ns-vol[ns3~/vol1])# volume-group 3
bstnA(gbl-ns-vol[ns3~/vol1])# ...
```

assigns two volumes to different volume groups. If /vol1 has a catastrophic metadata failure, /vol2 is unaffected. This also means that both volume groups are dedicated to the "ns3" namespace.

```
bstnA(gbl-ns[archives])# volume /multimedia
bstnA(gbl-ns-vol[archives~/multimedia])# no volume-group
bstnA(gbl-ns-vol[archives~/multimedia])# ...
```

commits the "/multimedia" volume to default-group assignment.

[share \(gbl-ns-vol-sfarm\)](#)  
[max-volume-groups](#)

## wait-for shares-online

**Purpose** Use the `wait-for shares-online` command to wait until all shares in a volume are enabled, and have started their imports.

**Mode** (any)

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `wait-for shares-online namespace volume [timeout timeout]`

*namespace* (1-30 characters) identifies the namespace.

*volume* (1-1024 characters) is the name of the volume.

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - 0 (zero, meaning that the command should wait indefinitely)

**Guidelines** This command is useful in CLI scripts.

When enabling a volume (`enable (gbl-ns, gbl-ns-vol)`) or all of its shares, you can use the `wait-for shares-online` command to wait for the volume's shares to be enabled. This command waits for all shares in the given volume.

Once this command returns, clients can access the shares and use them. The volume continues to import the shares as the clients access them.

If you set a *timeout* and it expires before all of the shares are online, the command exits with a warning.

**Sample** `bstnA(gbl-ns-vol[ns77~/vol31])# wait-for shares-online ns77 /vol31  
timeout 60`

waits for all shares from the 'ns77~/vol31' volume to come online. If 60 seconds expire before this happens, the command exits with a warning.

**Related Commands** `enable (gbl-ns-vol-shr)`

---

## wait-for volume-disable

**Purpose** After disabling a volume or namespace, you can use the `wait-for volume disable` command to wait for the volume(s) to go offline.

**Mode** (any)

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `wait-for volume-disable namespace [volume] [timeout timeout]`

*namespace* (1-30 characters) identifies the namespace.

*volume* (optional, 1-1024 characters) is a particular volume.

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - 0 (zero, meaning that the command should wait indefinitely)

**Guidelines** This command is useful in CLI scripts.

When disabling a volume or a namespace (no `enable (gbl-ns, gbl-ns-vol)`), you can use the `wait-for volume-disable` command to wait for one or all volumes to go offline.

If you set a *timeout* and it expires before all the chosen volumes are enabled, the command exits with a warning.

**Sample** `bstnA(gbl-ns[medarcv])# wait-for volume-disable medarcv`  
waits for all volumes in the 'medarcv' namespace to be disabled. There is no timeout specified, so the CLI blocks until all volumes are offline.

**Related Commands** [enable \(gbl-ns, gbl-ns-vol\)](#)  
[wait-for volume-enable](#)

## wait-for volume-enable

**Purpose** Use the `wait-for volume enable` command to wait for one or more volumes to come online.

**Mode** (any)

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `wait-for volume-enable namespace [volume] [timeout timeout]`

*namespace* (1-30 characters) identifies the namespace.

*volume* (optional, 1-1024 characters) is a particular volume.

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - 0 (zero, meaning that the command should wait indefinitely)

**Guidelines** This command is useful in CLI scripts.

When enabling a volume or a namespace ([enable \(gbl-ns, gbl-ns-vol\)](#)), you can use the `wait-for volume-enable` command to wait for one or all volumes to come online. To wait for all of the shares in a single volume, you can use [wait-for shares-online](#) instead.

If you set a *timeout* and it expires before all the chosen volumes are enabled, the command exits with a warning.

**Sample** `bstnA> wait-for volume-enable wwmed timeout 120`  
waits for all volumes in the 'wwmed' namespace to be enabled. If 120 seconds pass before the last volume comes online, the command exits with a warning.

**Related Commands** [enable \(gbl-ns, gbl-ns-vol\)](#)

Global Server

---

---

---

## active-directory alias

**Purpose** A Windows client typically provides a *service-principal name* (SPN, such as “fs1” or “fs1.medarch.org”) when connecting to a virtual server. An Active-Directory (AD) SPN, as opposed to an IP address, is required for Kerberos authentication. Use the `active-directory alias` command to set an official SPN (or multiple SPNs) for this server.

Use the `no` form of the command to remove one of this server’s SPNs from the AD database.

**Mode** gbl-gs-vs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `active-directory alias name`  
`no active-directory [alias]`

*name* (1-256 characters; optional in the `no` form) is a SPN for the current global server. If you omit this from the `no` form of the command, it removes all SPNs for the virtual server. The CLI prompts for confirmation before removing all of the server’s SPNs.

**Default(s)** None

**Guidelines** This command is only relevant to a virtual server whose global server offers `cifs` service, and whose clients use Kerberos authentication.

The global server requires strong credentials for setting SPNs at a Domain Controller (DC). Before you run this command, go to `gbl-gs` mode and use the `active-directory proxy-user` command to identify a `proxy-user` with permissions to do this.

This command causes the ARX to set the given SPN at the local DC. To identify the DC where this is set, use `show global server` to find the Windows domain, then use `show active-directory domain domain-name` to map the domain to its DC(s).

The ARX software sets both a “HOST” SPN and a “CIFS” SPN, mapping them back to the virtual server’s VIP. This occurs if (and only if) both the virtual server and the global server are enabled (`enable (gbl-gs, gbl-gs-vs)`). You can run this command to store the SPN in the ARX database, and then enable the global and virtual server later to set the SPN at the DC. While both servers are running, you can re-set the SPN at the DC by removing it (with `no active-directory alias`) and adding it back.

**Guidelines: Setting the Same Aliases in DNS and/or WINS**

This command makes Kerberos authentication possible for clients that use the given SPN, but it has no effect on routing. That is, the SPN must also be set as a DNS alias and/or a WINS alias in your network. You can set up the global server so that it automatically registers its aliases at your local DNS or WINS server:

- from gbl-cifs mode, use [dynamic-dns](#) to register aliases with a DNS server;
- from gbl-gs mode, use [wins-name](#) or [wins-alias](#) to register aliases with a WINS server.

Conversely, if a DNS-based name exists for this global server that is different from the global server's FQDN, clients can connect to the ARX service but Kerberos authentication always fails. In this case, use the [active-directory alias](#) command to create the SPNs for the server's DNS-based FQDN. For example, if clients can use the DNS-based "ac1.wmed.com" to reach the "ac1.medarch.org" global server, use [active-directory alias ac1.wmed.com](#) to create the SPNs for that DNS-based name.

**Sample** `bstnA(gbl-gs-vs[ac1.medarch.org~192.168.25.15])# active-directory alias fs2`  
sets a new SPN, "fs2," for the virtual server at "192.168.25.15."

**Related Commands** [active-directory proxy-user](#)  
[enable \(gbl-gs, gbl-gs-vs\)](#)  
[dynamic-dns](#)  
[wins-name](#)  
[wins-alias](#)

---

# active-directory proxy-user

**Purpose** A Windows client typically provides a *service-principal name* (SPN, such as “insur.medarch.org”) when connecting to a global server. Kerberos authentication fails if the SPN is unregistered in the Active-Directory (AD). You use the [active-directory alias](#) command to register a SPN (or multiple SPNs) for this server. Use this command to assign Windows credentials (username, password, and Windows domain) for setting these SPNs.

Use the `no` form of the command to remove the proxy-user from this global server. This makes it impossible to set any more SPNs with the [active-directory alias](#) command.

**Mode** gbl-gs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `active-directory proxy-user name`  
`no active-directory proxy-user`

*name* (1-32 characters) is the Windows proxy user to associate with the current global server.

**Default(s)** None

**Guidelines** This command is only relevant to a global server that offers [cifs](#) service with Kerberos authentication.

From `gbl` mode, use the [proxy-user](#) command to add a proxy-user configuration to the ARX. Use the [show proxy-user](#) command to view all configured proxy-users and their associated usernames and Windows domains.

Choose a proxy user with privileges for setting SPNs at the local Domain Controller (DC). These privileges are stronger than those needed for a namespace. To find the local DC where the SPNs will be set, use [show global server](#) to find the Windows domain for this global server, then use [show active-directory domain \*domain-name\*](#) to map the domain to one or more DCs.

**Sample** `bstnA(gbl-gs[ac1.medarch.org])# active-directory proxy-user acoProxy2`  
associates proxy user “acoProxy2” with the current global server.

**Related Commands** [active-directory alias](#)  
[proxy-user](#)  
[show global server](#)  
[show active-directory](#)

## description (gbl-gs)

**Purpose** Use the optional `description` command to set a descriptive string for the current global server. This appears in the `show` command.

Use the `no` form of the command to delete the description.

**Mode** gbl-gs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-255 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** `no description`

**Guidelines** The description appears in the output for [show global server](#).

**Sample** `bstnA(gbl-gs[www.wmed.com])# description "global NFS server for network hospitals"`

specifies a description for the current global server.

**Related Commands** [global server](#)  
[show global server](#)

---

## enable (gbl-gs, gbl-gs-vs)

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## global server

**Purpose** A *global server* links a front-end NFS and/or CIFS service to a virtual-IP (VIP) address. Clients can access the front-end service(s) through the VIP. Use the **global server** command to create a global server.

Use the **no** form of the command to delete a global server.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **global server** *fqdn*  
**no global server** *fqdn*

*fqdn* (1-128 characters) is the fully-qualified domain name (for example, “eng-nfs.company.com”) that you choose for the global server. By convention, this is the name that clients use to access the global server.

**Default(s)** None

**Guidelines** When you use this command to either create or delete a global server, the CLI prompts for confirmation. Enter **yes** to proceed.

This command places you in **gbl-gs** mode. From there, you must use the **virtual server** command to bind the global server to the ARX. The virtual server runs the global server’s front-end services on its virtual-IP (VIP) address. Once you have a virtual server, you must configure and enable at least one front-end service to run on the global server; for example, you can use the **nfs** command to instantiate NFS service or the **cifs** command for CIFS service. You then use the **enable (gbl-gs, gbl-gs-vs)** command in **gbl-gs** mode to start the global server.

Global servers that offer CIFS as a front-end service require a Windows domain; configure the Windows domain with the **windows-domain (gbl-gs)** command. To support Kerberos authentication for multiple CIFS-service aliases, you will need to set each alias as a *service-principal name* (SPN); use **active-directory proxy-user** to choose a proxy user with permission to set these SPNs. (You can later use **active-directory alias**, in **gbl-gs-vs** mode, to set each SPN.)

You can configure an indeterminate number of global servers, but the number of *useful* global servers is limited by the maximum number of front-end services. The ARX-500 supports a maximum of 16 front-end services, and the remaining platforms support up to 64. This limit applies to the sum of all **cifs** services and **nfs** services.

To remove a global server, use the **no enable** command from **gbl-gs** mode, then exit to **gbl** mode and use the **no global server** command.

Use **show global server** to view the current configuration of the global server. To map the global server to the physical servers (filers) behind it, use **show server-mapping**. The **show statistics global server** command shows the volume of client traffic to the global server.

---

**Samples** bstnA(gbl)# **global server www.wwmed.com**  
This will create a new global server.

```
Create global server 'www.wwmed.com'? [yes/no] yes
bstnA(gbl-gs[www.wwmed.com])#
 instantiates a global server at www.wwmed.com.
```

```
bstnA(gbl)# global server www.defunctcompany.com
bstnA(gbl-gs[www.defunctcompany.com])# no enable
bstnA(gbl-gs[www.defunctcompany.com])# exit
bstnA(gbl)# no global server www.defunctcompany.com
Delete global server 'www.defunctcompany.com'? [yes/no] yes
bstnA(gbl)# ...
 removes the global server that was running at www.defunctcompany.com.
```

**Related Commands** [enable \(gbl-gs, gbl-gs-vs\)](#)  
[virtual server](#)  
[windows-domain \(gbl-gs\)](#)  
[active-directory proxy-user](#)

[show statistics global server](#)

## show global server

**Purpose** Use the `show global server` command to display configuration information about global servers.

**Mode** (any)

**Security Role(s)** operator

**Syntax** `show global server [fqdn]`

*fqdn* (1-128 characters) is the fully-qualified domain name (for example, “www.organization.org”) for one global server.

If you do not include the global server FQDN, the command displays all global server configurations.

**Guidelines** The output of this command is a large table with sub-tables. The table’s fields and sub-tables are described below.

**Domain Name** is the FQDN name for the global server.

**State** is the global server’s administrative state (enabled or disabled). Use [enable \(gbl-gs, gbl-gs-vs\)](#) to enable the global server.

**Windows Domain** is the Windows Domain through which [cifs](#) service (if any) is provided. By default, the “short-domain name” for the service is the first component of this domain (for example, “MYCO” is the short name for “MYCO.COM”). If something other than the default is used for this, it appears in parentheses after the name. Use the [windows-domain \(gbl-gs\)](#) command to change the domain and/or the short-domain name.

The global-server table also contains a sub-table describing all of its virtual servers:

**Switch** is hostname for the virtual server’s host switch. The *virtual server* runs the front-end services (NFS and/or CIFS) on behalf of the global server. The virtual server has its own administrative state, VIP, and VMAC.

**State** is enabled or disabled. Use [enable \(gbl-gs, gbl-gs-vs\)](#) to enable the virtual server.

**VIP** is the virtual IP (VIP) address, where clients connect to the virtual server. Use [virtual server](#) to set this.

**VLAN** is the VIP’s VLAN number, also set with [virtual server](#).

**VMAC** is the virtual MAC (VMAC) address for the VIP.

- Guidelines (Cont.)** Two additional sub-tables, labeled **Aliases**, show the various CIFS aliases for the service.
- The **SPNs** table shows the server's Active-Directory aliases. These are also known as Service-Principal Names (SPNs). If any are defined, the table contains two columns:
- Name** is an alias for this global server. If a client uses this name to connect to the global server, the client can authenticate with Kerberos. Each alias (or SPN) has two instances: one "CIFS" instance and one "HOST" instance. You can use the [active-directory alias](#) command to add an alias for the global server.
  - Active Directory Status** indicates the status of the SPN in both the AD database and the ARX database. "OK" indicates that the alias is in both databases, "Not Found" indicates that the AD database is missing the SPN, "Unmanaged" means that the AD database has the SPN but it was not configured on the ARX, and "Unknown" appears when the ARX failed to contact the DC or the DC returned an empty list of SPNs.
- The **WINS** table shows the WINS alias for the global server.
- WINS Name** is the NETBIOS name of the CIFS service, set by the [wins-name](#) command.
  - WINS Server** is the address of the local WINS server, set by the [wins](#) command.
- Description** is a string to describe the global server. You can set this with the [description \(gbl-gs\)](#) command.

- Samples**
- ```
bstnA> show global server
```
- shows all the global servers on the ARX. See [Figure 23.1](#), below.
- ```
bstnA> show global server www.wwmed.com
```
- shows one global server, "www.wwmed.com."

- Related Commands**

# show server-mapping

**Purpose** Use the `show server-mapping` command to map shares on the client side of the switch to the physical servers behind it.

**Mode** (any)

**Security Role(s)** operator

**Syntax** `show server-mapping [namespace name | virtual-ip vip]  
[ip-addresses]  
show server-mapping status [ip-addresses]`

*name* (optional, 1-30 characters) identifies one namespace on which to focus.

*vip* (optional) specifies that you want to focus on the chosen Virtual IP (VIP) address.

*ip-addresses* (optional) converts all external-filer names into IP addresses in the output.

*status* (optional) shows a one-word status for each back-end server.

If you do not include any options, the command shows all VIPs and namespaces.

**Guidelines** Virtual Server is the VIP address and name for one share on one virtual server. Use [virtual server](#) to create a virtual server. Then use [cifs](#) and [export \(gbl-cifs\)](#) to create a CIFS share, and/or use [nfs](#) and [export \(gbl-nfs\)](#) to create an NFS export.

Namespace/Volume is served by the front-end share. This is a virtual storage pool behind the share which connects to the Physical Server(s) below.

Virtual Path appears only for a [direct](#) volume. This is the *attach point* from the volume to a mount point or CIFS share on one of the filers. Clients see each of these paths as a sub-tree under the root of the front-end export/share. You can use the [attach](#) command to create an attach point to a filer share.

Physical Server is one of the server shares behind a namespace. If this has an asterisk (\*) at the end, it is used as a metadata-only share (created with [metadata share](#)). A double-asterisk (\*\*) indicates that the server is a managed volume that a [direct](#) volume is using as though it were a back-end filer; you can use the [managed-volume](#) command to use a managed volume this way.

For the *status* command, the output shows the status of each Virtual Server and Physical Server in the above output. A new field, Status, has a different interpretation for each server type:

Status for the Virtual Server is an abbreviation for the [show virtual service](#) status. A status of “Ready” indicates that the service is functional. Refer to that command’s documentation for details.

Status for the Physical Server is an abbreviation for the share’s import status, as seen in [show namespace](#). See [Table 21.1 on page 21-49](#) for details. A status of “Online” indicates that the back-end share is functional.

**Samples** bstnA> `show server-mapping`

shows the physical servers behind all the global servers on the ARX. See [Figure 23.2](#), below.

bstnA> `show server-mapping namespace medarcv ip-addresses`

shows the virtual server(s) in front of the medarcv namespace, in addition to the physical server(s) behind it. The display shows the IP addresses for the physical servers instead of their external-filer names. See [Figure 23.3 on page 23-16](#).

bstnA> `show server-mapping status`

shows the status of all the virtual and physical servers. See [Figure 23.4 on page 23-18](#).

**Related Commands** [show virtual service](#)  
[show namespace](#)

## virtual server

**Purpose** A *virtual server* is the ARX that hosts a global server. Each virtual server has a virtual IP (*VIP*) address where the global server's front-end services listen for clients. Use the **virtual server** command to create a virtual server for the current global server.

Use the **no** form of the command to delete a virtual server from the current global server.

**Mode** gbl-gs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **virtual server** *switch-name* *vip* *mask* [*vlan* *vlan-id*]  
[*cluster* *cluster-name*]

**no virtual server** *switch-name* *vip* [*cluster* *cluster-name*]

*switch-name* (1-128 characters) is host name for the ARX.

*vip* is the IP address for the ARX to use when it runs front-end services for the current global server.

*mask* reveals the subnet-part of the VIP. All clients for this VIP should reside on this subnet or be reachable through this subnet via a static route ([ip route](#)).

**vlan** *vlan-id* (optional; 1-65535) identifies the VLAN that carries the above subnet.

*cluster-name* (optional, 1-64 characters) is only relevant if the ARX is part of a disaster-recovery (DR) configuration. In a DR configuration, there is an active ARX cluster with one set of files and a backup cluster with a mirrored set of files. This determines which cluster uses the *vip* and *mask*. Run the **virtual server** command twice per global server if you use DR: once to designate the *vip* and *mask* at the active cluster, and again to determine the *vip* and *mask* at the backup cluster. Use [show cluster](#) for a list of configured clusters. If you omit this, the CLI applies the change to the local cluster.

**Default(s)** *vlan-id* - 1

**Guidelines** This command places you in gbl-gs-vs mode. From there, you can establish the server's presence in your Windows network (if necessary), and start the virtual server. If there is a local WINS server, you can use the [wins](#) command to identify it. The default NetBIOS name for the virtual server is derived from the global server's FQDN (for example, "\\MYSERVER"); you can use [wins-name](#) to change the NetBIOS name. The [wins-alias](#) command registers one or more additional names for the server. To start the server, use the [enable \(gbl-gs, gbl-gs-vs\)](#) command.

Clients can access the global server's front-end service(s) through the VIP configured in this command. They must be on the same subnet established by the *vip* and *mask*, or they must be reachable through a static route (see [ip route](#)) where the next-hop gateway is in that subnet.

The CLI prompts you for confirmation if you use **no virtual server** to delete a virtual server; enter **yes** to proceed.

**Guidelines: Clusters** The CLI keeps the Windows names and aliases consistent for both clusters. Whether you enter `gbl-gs-vs` mode for cluster A or cluster B, there is only one set of `wins`, `wins-name`, or `wins-alias` parameters that are shared with both clusters. Only the `vip` and `mask` are unique to each cluster.

**Guidelines: External DNS Config** Clients can access the same front-end services through the `global server`'s FQDN (for example, `www.mybusiness.com`) if you use a naming service (such as DNS) to map the `global server`'s FQDN to the VIP address. Set up an alias on your external name server.

**Guidelines: DNS Config Required for Kerberos** For virtual servers that offer CIFS service and use Kerberos authentication, the above naming-service configuration is required. Kerberos does not allow the use of IP addresses for connecting with the virtual IP. To simplify maintenance, you can configure dynamic DNS as part of the CIFS service: use `name-server` to identify the DNS server for each domain in the Active-Directory (AD) forest, then use `dynamic-dns` to map a host name to the VIP. Finally, use `active-directory alias` to register the same name as a valid SPN for this server. With this configuration, the CIFS service automatically updates the local DNS servers with any configuration changes.

**Samples**

```
bstnA(gbl-gs[www.wvmed.com])# virtual server bstnA 192.168.25.10
255.255.255.0 vlan 25
bstnA(gbl-gs-vs[www.wvmed.com~192.168.25.10])#
 adds the current ARX, "bstnA," as a virtual server for the current global server.
 The switch listens at VIP 192.168.25.10; it offers all of the global server's
 front-end services at that IP address. Each front-end service listens, by default, at
 its well-known TCP and/or UDP port on the VIP.
```

```
provA(gbl-gs[provmed.medarch.org])# virtual server newptA 192.168.8.145
255.255.255.0 vlan 80 cluster newport
```

```
% INFO: Cluster 'newport' is not the local cluster. This configuration
option will not take effect on this switch.
```

```
provA(gbl-gs-vs[provmed.medarch.org])#
 adds a backup ARX, "newptA," as a virtual server for the "newport" cluster. The
 switch listens at VIP 192.168.8.145; it offers all of the global server's front-end
 services at that IP address.
```

```
bstnA(gbl-gs[www.wvmed.com])# no virtual server bstnA 192.168.25.14
Delete virtual server '192.168.25.14' on switch 'bstnA'? [yes/no]
yes
```

removes the current switch from the current global server.

---

# wait-for vip-enable

**Purpose** Use the `wait-for vip-enable` command to wait until the Virtual IP (VIP) is ready.

**Mode** (any)

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `wait-for vip-enable vip [timeout timeout]`

*vip* (0.0.0.0. to 255.255.255.255) is the VIP.

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - 0 (zero, meaning that the command should wait indefinitely)

**Guidelines** This command is useful in CLI scripts.

You can use this command after you use [enable \(gbl-gs, gbl-gs-vs\)](#) to start a virtual server. The CLI blocks until the VIP is available on the network.

This does not indicate that the virtual server behind the VIP is fully online. enabling all of the software in the virtual service and its backing namespace(s) can take several additional seconds.

If you set a *timeout* and it expires before the VIP is available, the command exits with a warning. To interrupt the `wait-for vip-enable` command, press **<Ctrl-C>**.

**Sample**

```
bstnA(gbl-gs-vs[www.wamed.com~192.168.25.10])# wait-for vip-enable
192.168.25.10
 waits until this VIP is available.
```

**Related Commands** [enable \(gbl-gs, gbl-gs-vs\)](#)  
[wait-for vip-disable](#)

## windows-domain (gbl-gs)

**Purpose** For global servers running CIFS as a front-end service (see [cifs](#)), use the `windows-domain` command to set the global server's Windows domain.  
Use `no windows-domain` to remove any Windows domain from the global server.

**Mode** `gbl-gs`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `windows-domain domain [pre-win2k-name short-name]`  
`no windows-domain`

*domain* (1-64 characters) is the domain name (for example, MYCOMPANY.COM).

*short-name* (optional, 1-15 characters) is the short, pre-Windows 2000 name for the domain. This is the domain's NetBIOS name. The default (below) should suffice for most situations, and this option should be unnecessary.

**Default(s)** *short-name* - The old-style name discovered with [active-directory update seed-domain](#). If the old-style name was never discovered for this domain, the ARX uses the first part (before the first ".", up to 15 characters) of the FQDN in the *domain-name*.

**Guidelines** You must set the Windows domain for global servers that offer CIFS as a front-end service.

The default for the short-domain name (sometimes called an "NT domain name") is sufficient for most installations. This name is automatically discovered with the [active-directory update seed-domain](#) operation. If that operation did not run or discovered no short name for this domain, this uses the first component in the long domain name, converted to uppercase: for example, if the domain is "group.bigco.com" the short domain name is "GROUP." You can use the `pre-win2k-name` option for rare cases where the short name is *not* one of these options (for example, the short name is "TEAM" instead of "GROUP", and the "TEAM" name is not set in the AD).

If *short-name* is completely different from the *domain* name, and the `cifs` service does not use constrained delegation (see [domain-join](#)), each backing namespace requires an additional `ntlm-auth-server`. The second `ntlm-auth-server` object is a copy of the one for the long-domain name ("group.bigco.com"), where the [windows-domain \(gbl-ntlm-auth-srv\)](#) is the short-domain name ("TEAM") and all other parameters are the same. Use the [ntlm-auth-server \(gbl-ns\)](#) command to associate the additional `ntlm-auth-server` object to the backing namespace.

**Samples** `bstnA(gbl-gs[insur.medarch.org])# windows-domain MEDARCH.ORG`  
sets the Windows domain to MEDARCH.ORG for the current global server.

`bstnA(gbl-gs[www.test.com])# no windows-domain`  
removes the Windows domain from the global server at www.test.com.

**Related Commands** [global server](#)  
[export \(gbl-cifs\)](#)

---

## wins

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | A WINS server resolves domain-based names (such as <code>www.mycompany.com</code> ) with IP addresses (such as <code>192.168.95.91</code> ). This is analogous to Domain Name Service (DNS), and is sometimes used instead of DNS in Windows networks. The virtual server registers its NetBIOS names with the WINS server when the service is enabled. Use the <code>wins</code> command to identify the local WINS server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Mode</b>             | <code>gbl-gs-vs</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Syntax</b>           | <code>wins ip-address</code><br><br><i>ip-address</i> is the IP address of the WINS server (for example, <code>192.168.70.65</code> ). This address must be on the proxy-IP subnet (established with the <code>ip proxy-address</code> command) or reachable through a gateway on that subnet (via static route: see <code>ip route</code> to create a static route).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Guidelines</b>       | The virtual server registers its NetBIOS names with the WINS server when you use <code>enable (gbl-gs, gbl-gs-vs)</code> to enable the virtual server. The registered NetBIOS names are the <i>computer</i> name and the <i>group</i> name. The default computer name is the first component of the global server's FQDN (for example, <code>"\FS1"</code> is the default for a global server at <code>"fs1.mycompany.com"</code> ). You can use the <code>wins-name</code> command to reset this computer name and <code>wins-alias</code> to add additional NetBIOS computer names. The NetBIOS group name is the <code>pre-win2k-name</code> from the <code>windows-domain (gbl-gs)</code> command (for example, <code>"MYCOMPANY"</code> ).<br><br>To set the character encoding for these name registrations, you can use <code>cifs fqdn</code> to reach <code>gbl-cifs</code> mode, then use <code>wins-name-encoding</code> . |
| <b>Sample</b>           | <pre>bstnA(gbl-gs-vs[ac1.medarch.org~192.168.25.15])# wins 192.168.25.20</pre> sets the WINS server to <code>192.168.25.20</code> for the current virtual server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Related Commands</b> | <code>global server</code> -> <code>virtual server</code><br><code>wins-name</code><br><code>wins-alias</code><br><code>cifs</code><br><code>wins-name-encoding</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## wins-alias

**Purpose** You can use the `wins-name` command to set the NetBIOS computer name for the virtual server, and you can use the `wins-alias` command to add an additional NetBIOS alias.

Use `no wins-alias` to remove one or all NetBIOS aliases.

**Mode** `gbl-gs-vs`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `wins-alias alias`  
`no wins-alias [alias]`

*alias* (1-15 bytes; see below) is a NetBIOS alias you choose for the current virtual server. The alias must start with a letter, but can contain numbers and underscores (`_`) after the first character.

If you omit the *alias* from the `no` form of the command, the CLI deletes all aliases.

**Default(s)** `None`

**Guidelines** This only applies to virtual servers that support CIFS front-end services.

CIFS clients can connect to the virtual server using either the `wins-name` or any aliases you set with this command. You can issue the command multiple times to create multiple NetBIOS aliases.

When you run `enable (gbl-gs, gbl-gs-vs)` for the virtual server, the virtual server registers its computer name and all aliases with the WINS server.

The WINS server may use multi-byte character encoding to allow registration of NetBIOS names with Japanese, Korean, or other non-Latin characters. At the `cifs` service for this global server, use the `wins-name-encoding` command to set the character encoding for this registration.

For Latin-1 characters, a NetBIOS alias can be 15 characters (one character per byte); for non-latin, multi-byte characters, you are limited to a smaller number of characters.

**Guidelines: Kerberos Support** If any of the CIFS front-end services support Kerberos authentication, additional configuration is required in the Active Directory for these WINS aliases. The `domain-join` command registers its CIFS-service FQDN at the Active-Directory (AD) domain; if a client connects to the service using a WINS alias, the local Domain Controller (DC) must be able to translate the WINS alias into the registered FQDN. Otherwise, Kerberos authentication fails.

You can use the `active-directory alias` command to set a SPN for the CIFS service's global server.

---

**Samples** `bstnA(gbl-gs-vs[fs.nt.org~192.168.25.12])# wins-alias HR_SERVER`  
sets a NetBIOS computer name of “HR\_SERVER” for the current virtual server.  
A Windows “Network Neighborhood” will display “\HR\_SERVER” for the  
current virtual server.

`bstnA(gbl-gs-vs[fs.nt.org~192.168.25.12])# no wins-alias HUMAN_RES`  
removes one NetBIOS alias.

**Related Commands** [global server](#) -> [virtual server](#)  
[wins-name](#)  
[cifs](#)  
[wins-name-encoding](#)

## wins-name

**Purpose** The default NetBIOS computer name for a virtual server is the first component of the global server's FQDN (for example, "\FS1" is the default for a global server at "fs1.mycompany.com"). Use the `wins-name` command to set another NetBIOS computer name.

Use `no wins-name` to revert to the default NetBIOS name.

**Mode** gbl-gs-vs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `wins-name name`  
`no wins-name`

*name* (1-15 bytes; see below) is the NetBIOS name you choose for the current virtual server. The name must start with a letter, but can contain numbers and underscores ( \_ ) after the first character.

**Default(s)** The default NetBIOS name is the first component of the global server's FQDN (for example, "\MYSERVER" is the default for a global server at "myserver.myorg.org"). If this is longer than 15 bytes, the switch only uses the first 15 bytes.

**Guidelines** This only applies to virtual servers that support CIFS front-end services. The virtual server registers its NetBIOS names with the WINS server when you [enable \(gbl-gs, gbl-gs-vs\)](#) the virtual server. The registered NetBIOS names include both the computer name and the domain name. The WINS server may use multi-byte character encoding to allow registration of NetBIOS names with Japanese, Korean, or other non-Latin characters. At the [cifs](#) service for this global server, use the [wins-name-encoding](#) command to set the character encoding for this registration. For Latin characters, a NetBIOS name can be 15 characters (one character per byte); for non-latin, multi-byte characters, you are limited to a smaller number of characters. The limit is 15 bytes, not simply 15 characters. To add additional NetBIOS names to this virtual server, use the [wins-alias](#) command.

**Guidelines: Kerberos Support** If any of the CIFS front-end services support Kerberos, additional configuration is required in the Active Directory for this WINS name. The [domain-join](#) command registers its CIFS-service FQDN at the Active-Directory (AD) domain; if a client connects to the service using a different WINS name, the local Domain Controller (DC) must be able to translate the WINS name into the registered FQDN. Otherwise, Kerberos authentication fails.

You can use the [active-directory alias](#) command to set a SPN for the CIFS service's global server.

**Sample** `bstnA(gbl-gs-vs[fs.nt.org~192.168.25.14])# wins-name PERSONNEL`  
sets the NetBIOS computer name to "PERSONNEL" for the current virtual server. A Windows "Network Neighborhood" displays "\PERSONNEL" for the current virtual server.

Front-End Services

---

# browsing

**Purpose** An MMC user can share out storage from a remote CIFS filer, and MMC offers an opportunity to browse the filer's volumes so that the user can choose one of them for sharing. The CIFS service does not support this browsing feature by default. Use the `browsing` command to enable this type of MMC browsing for one namespace behind the current CIFS service.

Use `no browsing` to disallow this MMC browsing for one namespace (or all namespaces) behind the CIFS service.

**Mode** `gbl-cifs`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `browsing namespace`  
`no browsing [namespace]`

*namespace* (1-30 characters) chooses a namespace behind this CIFS service. This makes the namespace's volumes visible to MMC clients who "browse" the namespace's volumes before choosing one for sharing. (In a multi-protocol namespace, the backing namespace might be established by an NFS export for the same global server.)

**Default(s)** `no browsing`

**Guidelines** After you enable browsing, authorized Windows clients can use MMC browsing to share any volume in the chosen namespace. If you want MMC clients to use this feature for multiple namespaces behind this CIFS service, repeat this command for each desired namespace.

You authorize a client by adding it to a Windows-management-authorization (WMA) group; use the `windows-mgmt-auth` command to create one such group. The `show windows-mgmt-auth` command shows all members and permissions for a group. Use the `windows-mgmt-auth (gbl-ns)` command to assign a WMA group to the backing namespace(s); you can use the command more than once to associate multiple groups with the namespace. All namespaces behind this CIFS service must have a matching set of WMA groups.

Authorized WMA users can share the service's backing volumes with MMC instead of the `export (gbl-cifs)` command. With browsing enabled, MMC clients have an added convenience: they can browse all of the namespace's volumes and share the one(s) they want.

**Guidelines:**  
**CIFS-Share Names for  
Backing Namespaces**

From the Windows-management interface, management clients see all of a namespace's managed volumes as directories under a single CIFS share. The share names are "C\$," "D\$," and so on. There is one such share for each namespace. If the namespace is exported by multiple CIFS services, it uses that same share name for all of them.

Each direct volume appears as a separate root, "Z\$," "Y\$," and so forth. These share names are also the same for every CIFS service that exports the namespace.

The ARX software assigns these share names to a namespace and its direct volume(s) when you issue this command. The share-name assignments persist as long as browsing is enabled for the namespace from any CIFS service.

There is a maximum of 26 such share names. Each namespace with browsing enabled uses one share name for all of its managed volumes plus one for each direct volume. You cannot enable browsing for a namespace if it contains enough volumes to exceed 26 share names. If you disable browsing for a given namespace in all CIFS services, its share names are available for use by other namespaces.

**Samples**

`bstnA(gbl-cifs[ac1.medarch.org])# browsing medarcv`  
enables MMC browsing for the "medarcv" namespace behind the "ac1.medarch.org" service. This is a convenience for using MMC to share out medarcv's volumes.

`bstnA(gbl-cifs[testSrvr])# no browsing demo2`  
disables MMC browsing for a namespace behind the "testSrvr" service.

[windows-mgmt-auth \(gbl-ns\)](#)  
[show windows-mgmt-auth](#)

---

## cifs

**Purpose** Use the `cifs` command to instantiate a CIFS service for a global server.  
Use the `no` form of the command to delete a CIFS-service instance.

**Mode** `gbl`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `cifs fqdn`  
`no cifs fqdn`

*fqdn* (1-128 characters) is the fully-qualified domain name (for example, “myserver.organization.org”) for an existing global server. Use [show global server](#) to see a list of global servers.

**Default(s)** `None`

**Guidelines** This command prompts for confirmation before creating the CIFS service; enter **yes** to continue. (To prevent confirmations for creating these sorts of configuration objects, use the [terminal expert](#) command.)

After you confirm, the CLI places you in `gbl-cifs` mode. From `gbl-cifs` mode, you must use the [export \(gbl-cifs\)](#) command to share at least one managed volume through CIFS. Use [domain-join](#) to register as a valid CIFS service with a Windows Domain Controller (DC). This creates a machine account in the Active Directory for the *fqdn* service, or uses an existing machine account if one already exists for *fqdn*. At a DC, an authorized administrator must raise the “Trusted for Delegation” flag for this service, and should also list the filers to which it can delegate; from `priv-exec` mode, you can use [probe delegate-to](#) to find all filers behind the CIFS service.

You then use the [enable \(gbl-cifs, gbl-nfs\)](#) command to start the CIFS service. Finally, map the service’s *fqdn* to its VIP with the [dynamic-dns](#) command. Windows clients can then map their network drives to the volumes exported by the CIFS service. Each exported volume appears on the Windows network as one share on the CIFS service’s *fqdn*. To add additional service-principal names for this CIFS service, to which clients could also connect, use the [active-directory alias](#) command from `gbl-gs-vs` mode.

Dynamic DNS names for a CIFS service are registered at external DCs, and all must be removed (with `no dynamic-dns`) before you can remove the CIFS service (with `cifs`).

**Guidelines: NetBIOS Name(s)** The NetBIOS name for the CIFS service is tied to the [virtual server](#). Each virtual server registers a NetBIOS name with its local WINS server. From `gbl-gs-vs` mode, use the [wins](#) command to identify the WINS server for a virtual server. From the same mode, you can optionally use [wins-name](#) to set the NetBIOS name for the virtual server and [wins-alias](#) to set additional aliases; by default, the NetBIOS name is the first part of the global server’s FQDN (for example, “\ATHOS” for the global server at “athos.myco.com”).

**Guidelines: Maximum Front-End Services** The ARX-500 supports a maximum of 16 front-end services, and the other platforms support up to 64. This limit applies to the sum of all CIFS services (created by this command) and NFS services (created with the [nfs](#) command).

**Guidelines: Show Commands** There are several CLI commands for monitoring and managing client access to CIFS shares. The [show cifs-service exports](#) command shows the connection statistics for each CIFS share/export. Use [show cifs-service user-sessions](#) to find clients with open CIFS sessions. To disconnect a client session, use [drop cifs-service user-session](#). The [show cifs-service open-files](#) command shows all files that are currently open through CIFS (and locked against reads). The policy engine cannot migrate or copy a file in this state; use [close cifs file](#) to close one from the CLI.

For CIFS-authentication statistics, including numbers for client authentications with the CIFS service as well as ARX authentications at back-end filers, use the [show statistics cifs authentication](#) command. For NTLM-authentication statistics, use [show statistics domain-controller](#).

**Samples**

```
bstnA(gbl)# cifs www.mycompany.com
This will create a new CIFS service.

Create CIFS service 'www.mycompany.com'? [yes/no] yes
bstnA(gbl-cifs[www.mycompany.com])#
 instantiates CIFS service at www.mycompany.com.
```

```
bstnA(gbl)# no cifs www.defunctcompany.com
Delete CIFS service on 'www.defunctcompany.com'? [yes/no] yes
bstnA(gbl)#
 removes the CIFS-service instance that was running at
 www.defunctcompany.com.
```

---

## cifs rekey

**Purpose** Some Kerberos DCs have an option to assign a “maximum age” for their machine-account passwords. Each machine uses its secret password to authenticate with the AD domain. (An ARX-CIFS service is treated as a machine in this context.) If the secret password expires, the CIFS service cannot use Kerberos for client authentication. You can use the `cifs rekey all` command to refresh the secret password (or key) for every CIFS service on the ARX.

**Mode** `priv-exec`

**Security Role(s)** `network-technician, network-engineer, storage-engineer, or crypto-officer`

**Syntax** `cifs rekey all`

`all` is required. If you rekey any CIFS service on the ARX, you rekey all of them at once.

**Default(s)** `None`

**Guidelines** If the ARX has a redundant peer, you can only perform this command on the active peer.

Most sites do not set expiration times for these machine-account keys. This command is only required if the local AD policy sets a maximum age for these keys. This only affects CIFS services that use Kerberos and have joined a domain (with the [domain-join](#) command).

### ◆ Note

*This causes a brief outage for every Kerberos-supporting CIFS service as it resets its secret key and restarts. The outage is brief enough that it should not be perceptible to any ARX clients.*

A CLI prompt warns you of the service outage; enter **yes** to continue with the rekey operation. If you proceed, the CLI lists all of the affected CIFS services.

Run this command before any CIFS service’s password expires. If a CIFS service’s password has already expired, use [domain-join](#) to rejoin the AD domain.

**Sample** `bstnA# cifs rekey all`

```
WARNING: Confirming this operation will cause the ARX to reset the
machine account password for all Kerberos-enabled CIFS services on the
switch. This will cause an outage of 30-60 seconds for all CIFS/NFS
services on the switch.
```

```
Proceed [yes/no] yes
```

```
The machine account password for CIFS service 'ac1.medarch.org'
successfully changed.
```

```
bstnA# ...
```

```
resets the machine-account keys for all CIFS services on “bstnA.”
```

**Related Commands** [at](#)  
[domain-join](#)

## clear dynamic-dns

**Purpose** A CIFS service can use dynamic DNS to register its host name and/or aliases in DNS. When you remove a host name or change the VIP, the CIFS service attempts to remove the DNS entry. If the remove fails after several retries, the [show dynamic-dns](#) output keeps a record of the failed removal indefinitely, to remind you to remove the “A” record from the DNS server itself. Use the `clear dynamic-dns` command to clear all failed DNS removals from the system.

**Mode** priv-exec

**Security Role(s)** network-engineer, storage-engineer, or crypto-officer

**Syntax** `clear dynamic-dns`

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before clearing all failed DNS-remove records from the ARX. Enter **yes** to proceed.

The [dynamic-dns](#) command causes a CIFS service to add or remove DNS-host names from a local DNS server. The CIFS service retries every minute on failure; it retries add operations indefinitely, but eventually stops retrying for remove operations. These remove operations show up with “Failed” status in the [show dynamic-dns](#) output. “Failed” removals persist in the show output until someone clears them. Use the `clear dynamic-dns` command to clear all failed DNS removals from the system.

**Sample**

```
bstnA# clear dynamic-dns
Clear failed dynamic DNS entries? [yes/no] yes
bstnA#
clears all failed DNS-removal entries from the system.
```

**Related Commands** [dynamic-dns](#)  
[show dynamic-dns](#)

## clear nlm locks

**Purpose** The NFS Lock Manager (NLM) manages file locks for NFS clients. Use the `clear nlm locks` command to clear all locks for all clients, or for a given client machine.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

**Syntax** `clear nlm locks {all | host-name}`

`all` | *hostname* is a required choice:

`all` clears all locks for all NFS clients, system-wide.

*hostname* (1-192 characters) clears all locks held by one client's host machine (for example, "myhost").

**Default(s)** `None`

**Guidelines** An NFS client can lock a file or a region within a file, so that other NLM-compliant users cannot access the region until the lock is released. The ARX's NLM server manages all the locks for all NFS front-end services and volumes.

### Important

---

*Never clear the locks for a running client. If the client still has locks, it has no way of knowing that those locks have been invalidated: the NLM protocol does not support a "clear all locks" message to the client. This could result in two different clients having an exclusive lock on the same file region, which typically corrupts the file.*

To see all the client machines that hold locks for a given file, use the `show nlm file` command. For a list locks held by a given client machine (or a list of all the client machines that have locks), use the `show nlm client` command. Use `show nlm statistics` to see statistics for all NLM activity.

To disable NLM for a given NFS service, disable NFS first (with `enable (gbl-cifs, gbl-nfs)`) and then use `no nlm enable`.

**Sample** `bstnA# clear nlm locks client18`  
clears all NFS locks held by the client machine, "client18."

**Related Commands** `show nlm file`  
`show nlm client`  
`show nlm statistics`  
`nlm enable`

---

## description (gbl-cifs)

**Purpose** Use the optional `description` command to set a descriptive string that appears as a comment in the Windows “Network Neighborhood.”

Use the `no` form of the command to delete the description.

**Mode** gbl-cifs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-48 characters) is your description. Surround the text with quotation marks (“”) if it contains any spaces.

**Default(s)** no description

**Guidelines** The server description appears as a comment for all browser views of the Windows network. It describes this CIFS service. This description also appears in the output for [show cifs-service](#).

**Sample** `bstnA(gbl-cifs[www.medarcv.com])# description “archives for Longwood Ave”`

specifies a description for the current CIFS service.

**Related Commands** [cifs](#)  
[show cifs-service](#)

## description (gbl-nfs)

**Purpose** Use the optional **description** command to set a descriptive string for the NFS service. This appears in the show command.  
Use the **no** form of the command to delete the description.

**Mode** gbl-nfs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **description** *text*  
**no** **description**

*text* (1-255 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** no description

**Guidelines** The description appears in the output for [show nfs-service](#).

**Samples** bstnA(gbl-nfs[www.wmed.com])# **description** "mount point for wmed storage"  
specifies a description for the current NFS service.

**Related Commands** [nfs](#)  
[show nfs-service](#)

---

# domain-join

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>domain join</code> command to register a CIFS front-end service with its Active-Directory (AD) domain. This is similar to adding client computers to the Active Directory domain, and it requires a sufficiently-privileged username and password. An administrator with stronger credentials can pre-create an account at the DC before you run this command, or the command can automatically enable delegation privileges at the DC. |
| <b>Mode</b>             | <code>gbl-cifs</code>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Security Role(s)</b> | <code>storage-engineer</code> or <code>crypto-officer</code>                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>           | <code>domain-join <i>domain-name</i> [ou "<i>organizational-unit</i>"]<br/>[<i>delegation</i> {<i>constrained</i>   <i>unconstrained</i>   <i>none</i>}]<br/>[<i>timeout seconds</i>]</code>                                                                                                                                                                                                                                                          |

*domain-name* (1-256 characters) is the Windows domain to join. This domain must be the global server's domain, and it must be part of the Active-Directory forest configuration (see [active-directory update seed-domain](#) or [active-directory-forest](#)). The CIFS service registers with one of the DCs that manage this domain.

*organizational-unit* (optional, 1-512 characters) is the *Organizational Unit* (OU) to which this service should be added. A Windows domain is divided into OUs for administrative convenience: each OU is a group of machines or accounts that are managed by a single administrator. Surround the OU name with quotation marks (""); OU names often contain spaces. Use a slash (/) to separate each layer in a nested OU: for example, ou "Virtual Services/pharmaceuticals" is a valid nested OU. This is the reverse of the LDAP path shown on the Windows server, which would be ".../cn=ac1,ou=pharmaceuticals,ou=Virtual Services,dc=medarch,dc=org."

*delegation* {*constrained* | *unconstrained* | *none*} (optional) is unnecessary if the CIFS-service account already exists in the local AD. Omit this option if an AD administrator pre-created the machine account for this service. Otherwise, the ARX automatically generates the account on a DC that manages this domain. This option determines which "Trust for delegation" flag (if any) to be used for the CIFS service. The command enables this delegation at the DC if (and only if) you have sufficient privileges to do so:

**constrained** is recommended, though it is only possible if the AD forest has a "Domain Functional Level" of Windows 2003 or later. This sets the "Trust ... for delegation for specified services" flag for the CIFS service. You (or an authorized administrator) can then access the DC and specify all of the back-end filers to whom this service can delegate. Once all the service's filers are on its "delegate-to" list at the DC, clients can authenticate once and then access CIFS storage on all those filers. (You can use the [probe delegate-to](#) command to confirm that all of the filers behind the CIFS service are properly configured at the DC.) The DCs allow clients to use NTLM, NTLMv2, or Kerberos to authenticate; at the namespace(s) behind the CIFS service, you can use [cifs authentication](#) to support any or all of these authentication types.

**Syntax (Cont.)**

**unconstrained** only works for Kerberos authentication (by default). This sets the “Trust ... for delegation to any service” flag for this CIFS service. Clients cannot connect to any back-end storage with NTLM or NTLMv2 if this flag is raised at the DCs. To support NTLM authentication together with this option, you must install a Secure Agent at one of your DCs; see [ntlm-auth-server](#).

**none** does not trust this CIFS service for any delegation. This makes it impossible for Kerberos clients to authenticate to this service. (NTLM/NTLMv2 clients cannot authenticate either, unless you install a Secure Agent on your DCs and use the [ntlm-auth-server](#) command.) Use this when you do not have sufficiently strong Windows credentials to raise any “Trust for delegation” flag. This presumes that an authorized administrator will raise the appropriate “Trust for delegation” flag at a later time, thereby opening access to CIFS clients.

**seconds** (optional, 1-300) sets a time limit for the domain-join operation. Use this in case the DC is too slow to respond before the command times out.

**Default(s)**

**organizational-unit**, if omitted, defaults to “Computers” at the domain’s root.

**delegation**, if omitted, is **unconstrained**.

**timeout seconds** is 90 seconds

**Guidelines: Before  
You Join**

To support CIFS-client authentication, the namespace(s) behind this CIFS service must have the desired authentication types enabled. Use the `gbl-ns cifs authentication` command to enable Kerberos, NTLM, and/or NTLMv2 for a namespace.

Additionally, the Active-Directory forest must be accurately reflected in the switch configuration (see [active-directory update seed-domain](#) or [active-directory-forest](#)), and the global server’s FQDN must be in one of the forest’s domains (the [forest-root](#), a [tree-domain](#), or a [child-domain](#)). You can use [show active-directory](#) to see all of the domains discovered in the AD forest.

**Guidelines: Minimal  
Windows Privileges  
Needed for a  
Domain-Join**

After you issue this command, the CLI prompts for a username and password. These are the credentials to be presented to the DC, called the *domain-joiner* credentials. In some sites, the domain-joiner credentials are sufficiently privileged to create a machine account on the DC and raise all of the proper flags. In other sites, a more-privileged user creates the machine account before the domain-joiner runs this command. These next subsections describe the minimal access privileges required to join the domain with either a new machine account or a pre-created account.

**New Machine Account**

If the *domain-joiner* has the following privileges, the domain-join operation can create a new machine account for the CIFS service. A pre-created machine account is unnecessary.

- In the “Computers” OU for the domain (or the OU chosen by this command), the user must have permission to “Create Computer Objects.”

On a Windows Server 2003 DC, you can set this in the “Active Directory Users and Computers” interface.

- The user must be able to “Enable computer and user accounts to be trusted for delegation.”

On a Windows Server 2003 DC, you can find this under “Domain Controller Security Policy.”

This is only required if you use some form of delegation, either constrained or unconstrained. It is unnecessary if you specify **delegation none**.

### Guidelines: Minimal Windows Privileges Needed for a Domain-Join (Cont.)

#### Pre-Created Machine Account

If someone in another group pre-creates the machine account at the DC, that person must have the minimal privileges above. On a Windows Server 2003 DC, that person creates a new machine account in the “Active Directory Users and Computers” interface. The machine account requires the following minimal settings:

- Set the machine account’s “Delegation” tab as desired.
  - We recommend “Trust this computer for delegation to specified services only” together with “Use any authentication protocol.” This is what the domain-join operation sets when it creates the account with the **delegation constrained** options.
- Add the domain-joiner’s user account into the machine account’s “Security” tab. Give the following permissions to that user:
  - Read
  - Write
  - Reset Password

Do not use any **delegation** options with a pre-created machine account. The delegation is already set at the DC, as described above.

### Guidelines: Switching a Joined Service to Constrained Delegation

If the CIFS service is already joined to the domain and you want to upgrade to constrained delegation, you can upgrade at the DC. From the DC, use the “Active Directory Users and Computers” interface to access the machine account for *fqdn*. (The machine account name is the first part of the *fqdn*: for example, the machine account name for “ac1.medarch.org” is “ac1”.) In the machine account’s properties, access the machine account’s “Delegation” tab and enter

- “Trust this computer for delegation to specified services only;”
- “Use any authentication protocol;” and
- the “delegate to” list at the bottom, which requires all the filers behind this CIFS service. All of the filers must be joined to the same Windows Domain as this CIFS service. See below if you are not aware of all the filers behind this service.

The CIFS service probes the DCs every few minutes to find these settings, so it may not be up-to-date right after you change them. You can use the [sync cifs delegation](#) command to update the CIFS service immediately. To verify success, wait for the DCs to synchronize with one another and then use the [show cifs-service fqdn](#) command to confirm the change. You can also use the [probe delegate-to fqdn](#) command to probe the DC and confirm that all the necessary filers are on the “delegate to” list. If any of these filers show up as “failed” on that list, enter those filers at the DC.

#### ◆ Note

*When you enter your filers at a Windows 2003 or 2008 DC, the following error may appear in a pop-up:*

**The following Active Directory error occurred: The specified directory service attribute or value already exists.**

*This indicates a software issue at the DC. Click OK to return to the Delegation tab, then check the **Expanded** box at the bottom. Look for duplicate SPNs in this expanded view; each filer should have only 2 SPNs, one with its FQDN and another with only its hostname. Remove all duplicate SPNs and then click Apply.*

**Guidelines: Switching  
a Joined Service to  
Constrained  
Delegation (Cont.)**

Once this is done for all of your [cifs](#) services, you can remove all ARX Secure Agent applications from your DCs. When constrained delegation is active in all CIFS services, the Secure Agent applications are ignored. For more information about Secure Agent, see the [ARX® Secure Agent Installation Guide](#).

**Guidelines: Verifying  
the Domain Join**

You can use the [show cifs-service fqdn](#) command to verify the success of the domain-join operation. This also shows the delegation type (constrained, unconstrained, or none) configured at the DC. If the service uses constrained delegation, this also lists the filers to which the service can delegate. The CIFS service probes the DCs every few minutes to update this information, so it may not be up-to-date right after you run the `domain-join` command.

The [probe delegate-to fqdn](#) command verifies that all of the filers behind the `fqdn` service are properly listed at the DC. This verifies that the “delegate to” list is correct and complete on the DC. If not, copy all failed filers from the ARX’s [probe delegate-to](#) output to the DC’s “delegate to” list.

◆ **Note**

---

*As described in the note above, an error may appear in a pop-up when you enter your filers at a Windows 2003 or 2008 DC. If the error appears, remove any duplicate filer SPNs (visible in the Expanded view) as described in the above note.*

**Guidelines: Name  
Length**

The CIFS service’s machine-account name is its FQDN by default, unless the hostname in the FQDN (“ac1” in “ac1.medarch.com”) is too long. If the hostname exceeds 15 bytes and the CIFS service uses the recommended constrained-delegation feature, DCs will reject the name for NTLM or NTLMv2 authentications. Therefore, the CIFS service uses only the first 15 bytes for the machine-account name. If the name is too long, a prompt informs you of the truncated account name that was registered at the DCs.

The shorter account name appears in the output of [show cifs-service](#).

**Guideline:  
Coexistence with  
NTLM**

If you use the `delegate constrained` option and properly configured the CIFS service at the DC, the service can support NTLM and Kerberos simultaneously. Each client negotiates the authentication protocol at the start of the CIFS session. The CIFS service uses Kerberos to authenticate with its back-end filers.

If you use the `delegate unconstrained` option, NTLM and NTLMv2 authentication is not supported by default. In this case, you can install a Secure Agent on some of your DCs to allow NTLM and/or NTLMv2 authentication. Then use [ntlm-auth-server](#) to identify each of these DCs, and [ntlm-auth-server \(gbl-ns\)](#) to use them in the namespace(s) behind this CIFS service. (The [show cifs-service fqdn](#) command shows the namespace(s) behind the `fqdn` service.) In this case, if a client connects with NTLM or NTLMv2, the CIFS service uses one of the NTLM protocols (preferably NTLMv2) to connect to the back-end filers.

All policy-initiated transactions with CIFS filers (such as file migrations) attempt to use Kerberos. The backing namespace negotiates the authentication method (Kerberos, NTLMv2, or NTLM) with each back-end filer. Kerberos requires that the backing namespace uses a proxy user configured with a full FQDN for its [windows-domain \(gbl-proxy-user\)](#). Kerberos also requires that it can discover the service-principal name (SPN) of each filer; you can use the [show exports](#) command to find if the filer allows for SPN discovery, or use [spn](#) to set the SPN manually.

**Guidelines: Resetting  
Machine-Account  
Passwords**

The domain-join operation involves the exchange of a shared password (or *key*). It is possible to set a “maximum age” for this type of machine-account key at the DC. If a maximum age is set at your site, you can later use the [cifs rekey](#) command to reset the CIFS service’s key before it expires. This makes the CIFS service automatically restart, so it causes a brief service outage.

You can also use the [at](#) command to reset the machine-account key on a regular schedule.

**Samples**

```
bstnA(gbl-cifs[ac1.medarch.org])# enable
bstnA(gbl-cifs[ac1.medarch.org])# domain-join MEDARCH.ORG
Username: jsmith
Password: jspasswd
```

```
% INFO: Service 'ac1' successfully joined the domain using a
pre-created computer account.
```

```
% INFO: Service 'ac1' joined the domain with delegation type set to
Constrained. Only certain selected services are allowed to be delegated
on 'ac1'. The Active Directory administrator must configure the
services 'ac1' may delegate to, which are the filer(s) this CIFS
service virtualizes.
```

```
bstnA(gbl-cifs[ac1.medarch.org])#
 joins the current CIFS service to its Windows domain using the credentials for
 jsmith. This uses a pre-created machine account; before issuing this CLI
 command, someone created a machine account for the CIFS service on a DC.
```

```
stkgA(gbl-cifs[bgh.medarch.org])# domain-join MEDARCH.ORG
Username: Administrator
Password: adminpasswd
```

```
% INFO: Service 'bgh' successfully joined the domain. The new computer
account was created.
```

```
% INFO: Service 'bgh' joined the domain with delegation type set to
Unconstrained. The delegation of services on 'bgh' is allowed only with
the Kerberos protocol.
```

```
 joins another CIFS service to its Windows domain using the credentials for
 Administrator. This creates a new machine account with unconstrained
 delegation. Unconstrained delegation does not support NTLM or NTLMv2 clients
 unless you also install a Secure Agent (see ntlm-auth-server) for the domain.
```

## dynamic-dns

**Purpose** Kerberos authentication requires up-to-date DNS records for every front-end CIFS service. Use the `dynamic-dns` command to register a host name or DNS alias for the current CIFS service.

Use the `no` form of the command to withdraw an alias from the local DNS database.

**Mode** `gbl-cifs`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `dynamic-dns alias`  
`no dynamic-dns alias`

*alias* (1-255 characters) is an alias for this CIFS service. This can be a simple host name (for example, “myserver”) or an FQDN (for example, “myserver.mycompany.com”). If it is a simple host name, the CIFS service appends the service’s Windows domain (set with `windows-domain (gbl-gs)`) before registering the name. If it is an FQDN, it must match that Windows domain or the CLI rejects it. Use `show global server` to see the Windows domain for the CIFS service (the Windows domain is set at the global server for the service).

**Default(s)** `None`

**Guidelines** Before you use this command, you must configure at least one DNS server for this service’s Windows domain. You can do this as part of setting up the Active-Directory (AD) forest; use the `gbl-forest name-server` command to identify the name server for the service’s domain. The Windows domain for this CIFS service is set in the service’s global server. Use `show global server` to see the Windows domain. You must also join an Active-Directory domain with `domain-join`. Finally, the CIFS service must be enabled (with `enable (gbl-cifs, gbl-nfs)`) before you issue this command.

This command immediately registers an address (A) record with one of the configured name servers. The “A” record maps the service’s virtual-IP (VIP) address to the alias you set in this command. (Use the `virtual server` command to set the VIP.) You can repeat this command to map multiple aliases to the VIP, so that clients can connect through multiple service names. All clients that connect through these names can use Kerberos authentication.

The CIFS service renews the “A” record registration at 1:00 AM (local time) each morning. It adds and or withdraws “A” records whenever the global server’s VIP changes (with `[no] virtual server`) or the CIFS service is removed (with `no cifs`). Use the `priv-exec dynamic-dns update` command to update all “A” records immediately.

The `no dynamic-dns` command causes the CIFS service to remove the A record from DNS. As with the affirmative syntax, you must issue the command while the CIFS service is enabled.

The `show dynamic-dns` command shows the dynamic-DNS configuration as well as the current status of all host-name registrations.

Basic DNS is defined in RFCs 1034 and 1035. RFC 3645 defines the Microsoft-specific authentication extensions for dynamic DNS. The ARX implementation adheres to all three RFCs.

The CIFS services only register “A” records, not “PTR” records for reverse lookups.

**Guidelines: Alias Support**

If the CIFS service has more valid hostnames than its FQDN, each additional hostname is a *DNS alias*. Each DNS alias must be established externally, in the Active Directory. The [domain-join](#) command registers its CIFS-service FQDN at the Active-Directory (AD) domain; if a client connects to the service using a DNS alias, the local Domain Controller (DC) must be able to translate the alias into the registered FQDN. Otherwise, Kerberos authentication fails.

From gbl-gs-vs (virtual server) mode, you can use the [active-directory alias](#) command to set a DNS alias for the CIFS service's global server. This registers the alias in the external Active Directory. Follow these instructions to reach gbl-gs-vs mode for the correct virtual server:

- Go back to gbl mode.
- Use the [global server fqdn](#), command, where *fqdn* is the one that identifies the CIFS service, too.
- Use the [virtual server](#) command to access the single virtual server under the global server.

**Samples**

```
bstnA(gbl-cifs[sales.myco.com])# dynamic-dns sales
bstnA(gbl-cifs[sales.myco.com])# dynamic-dns fs5.myco.com
registers two names for the current CIFS service.
```

```
bstnA(gbl-cifs[fs.myorg.org])# no dynamic-dns betafs
removes an alias, "betafs," from the current CIFS service.
```

[domain-join](#)  
[active-directory-forest](#)  
[active-directory alias](#)  
[dynamic-dns update](#)  
[show dynamic-dns](#)

## dynamic-dns update

**Purpose** Kerberos authentication requires up-to-date DNS records for every front-end CIFS service. If you use [dynamic-dns](#) for the current CIFS service, the CIFS service automatically updates its DNS server daily, or whenever a configuration change necessitates a change in DNS configuration. If you require an immediate update to your DNS server(s), use the `dynamic-dns update` command.

**Mode** `priv-exec`

**Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer` or `crypto-officer`

**Syntax** `dynamic-dns update [fqdn]`

*fqdn* (optional, 1-128 characters) identifies a single CIFS service for the update. If you omit this, all CIFS services send DNS updates to their local name servers.

**Default(s)** Perform the update for all CIFS services

**Guidelines** If you send DNS updates from all CIFS services, the CLI prompts for confirmation. If you have a large number of CIFS services, each with multiple host names to register, this can be a network-intensive operation. Enter **yes** to proceed.

You can register a new host name or DNS alias with the [dynamic-dns](#) command. This command sends an immediate update for all such host names. Under most circumstances, the update is redundant; the CIFS service sends updates daily, and sends changes whenever a VIP changes, a host name is removed, or some other IP/name change occurs. You can use this command to force an update if, for example, your external DNS servers have returned from an extended outage.

The [show dynamic-dns](#) command shows the dynamic-DNS configuration as well as the current status of all host-name registrations.

This command only affects CIFS services that are enabled ([enable \(gbl-cifs, gbl-nfs\)](#)).

**Samples** `bstnA# dynamic-dns update as1.medarch.org`  
sends DNS updates for the “as1.medarch.org” service. One “A” record is registered for each alias.

```
bstnA# dynamic-dns update
Update DNS host names for ALL CIFS services? [yes/no] yes
bstnA# ...
sends DNS updates for all CIFS services on the ARX.
```

**Related Commands** [dynamic-dns](#)  
[show dynamic-dns](#)

---

## enable (gbl-cifs, gbl-nfs)

**Purpose** Use the `enable` command to activate the current CIFS or NFS service.  
Use the `no` form of the command to stop the current CIFS or NFS service.

**Modes** gbl-cifs  
gbl-nfs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `enable`  
`no enable`

**Default(s)** Disabled

**Guidelines** The `enable` command makes all declared CIFS shares or NFS exports available to clients. Clients can access the share through the virtual-IP (VIP) address of the global server's [virtual server](#).

The CIFS service does not send any [dynamic-dns](#) updates unless it is enabled.

**Samples** `bstnA(gbl-cifs[ac1.medarch.org])# enable`  
enables the current CIFS service.

`bstnA(gbl-nfs[www.myorg.org])# enable`  
enables the current NFS service.

`bstnA(gbl-nfs[www.wmed.com])# no enable`  
disables the current NFS service.

**Related Commands** [cifs](#)  
[nfs](#)

## export (gbl-cifs)

**Purpose** Use the `export` command to share a namespace's managed volume through CIFS. Use the `no` form of the command to stop sharing a managed volume.

**Mode** gbl-cifs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax: Standard CIFS Share** `export namespace vol-path [as share-name] [description description]`  
`no export namespace vol-path`  
`no export as share-name`

*namespace* (1-30 characters) can be any namespace that supports CIFS. If the same CIFS service exports more than one namespace, all of the namespaces behind the service must have matching CIFS settings; see *Guidelines: Exporting from Multiple Namespaces*, below.

*vol-path* (1-1024 characters) is the path to one of the namespace's managed volumes (for example, "/multimedia") or inside the volume ("/multimedia/data/apps").

*as share-name* (optional; 1-1024 characters) sets an advertised path to the volume. If entered, CIFS clients see this path as an available export instead of the *volume* path. You can re-enter the command to share the volume under more than one share name.

*description description* (optional; 1-64 characters) sets a description for this share. This appears as a comment in Windows network browsers such as "Network Neighborhood" and the `net view` command. Surround the text with quotation marks ("") if it contains any spaces.

**Syntax: Filer Subshare** `export namespace vol-path as subshare-name filer-subshare [hidden] [description description]`  
`no export namespace vol-path`  
`no export as subshare-name`

is the syntax for exporting a filer subshare. A filer *subshare* is a CIFS share inside the volume's directory tree, below the root. At the back-end filer(s), a subshare often has a different share-level ACL than the root share.

*namespace* and *vol-path* are described above. The *vol-path* must be a valid path in a managed volume with [filer-subshares](#) enabled.

*as subshare-name* (optional; 1-1024 characters) is required for filer subshares. This is the name of the subshare for *vol-path* (for example, "MYSHARE"). If the CIFS service is enabled, this subshare is replicated on all back-end shares behind *vol-path*. This replicates the subshare's directory path, ACL, and attributes from the master directory to all other back-end shares. You can use the `find` command to find a directory's master directory. This replication operation is equivalent to running [sync subshares from-service](#).

**filer-subshare** is also required for filer subshares.

---

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax: Filer Subshare (Cont.)</b>          | <p><b>hidden</b> (optional) tells the CIFS service to find a hidden version of the <i>subshare-name</i> behind the volume, and expose it to front-end clients. The hidden subshare has a dollar-sign at the end of its name (such as “hidden_share\$”). With this option, the CIFS service exposes the subshare by exporting it without the “\$” suffix.</p> <p><b>description</b> <i>description</i> (optional; 1-64 characters) sets a description for this subshare, as explained above.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default(s)</b>                              | <p><i>share-name</i> defaults to the volume path without the leading slash (/), all in uppercase. For example, the “/var” volume would default to the share name, “VAR.”</p> <p><i>subshare-name</i> has no default.</p> <p><i>description</i> defaults to an empty string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Guidelines</b>                              | <p>This shares a managed volume or one of its subshares from any CIFS namespace. Clients can access this share through CIFS by accessing the share-name from their Windows Network Neighborhood.</p> <p>You can enter this command multiple times to share multiple managed volumes or subshares. You can also share one volume under multiple share names; for subshares, however, the share name must match the one used at the back-end filers. The ARX supports a maximum of 16000 CIFS exports.</p> <p>You must enable the CIFS service for any shares to be visible to clients. Use the <a href="#">enable (gbl-cifs, gbl-nfs)</a> command in gbl-cifs mode to enable CIFS service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Guidelines: Configuration at a Local DC</b> | <p>A new CIFS front-end share often requires some configuration at a local Domain Controller (DC). Best practices dictate that a CIFS service is trusted to delegate CIFS connections to all of the filers behind it, and it is not trusted to delegate CIFS to any other filer. This is called <i>constrained delegation</i>. The DCs manage the CIFS service’s ability to delegate, as well as the back-end filers to whom it can delegate. An authorized Windows administrator must therefore go to a DC and add this new volume’s filers to its CIFS service’s “delegate to” list.</p> <p>After you export the volume, you can use <a href="#">probe delegate-to fqdn</a> to check the DC(s) and determine whether or not delegation is properly configured for the new filers. If not, a properly authorized administrator must access the DC and add the new filer(s) to the CIFS service’s “delegate to” list.</p> <p>Every new filer must be joined to the same Windows Domain as the CIFS service, and it must support Kerberos authentication. The <a href="#">show cifs-service fqdn</a> command shows the domain to which the <i>fqdn</i> service is joined.</p> |
| <b>Guidelines: Subshares</b>                   | <p>Filer subshares are defined at back-end filers, along with all of their share-level ACLs. If you support subshares in the CIFS service, a client that connects to the subshare on the front end passes through to the corresponding subshare at the back-end; the share-level ACL is enforced there. Before using the <a href="#">filer-subshares</a> syntax, you must prepare the volume with the <a href="#">filer-subshares</a> command. Without the subshare preparation at both the CIFS service and the volume, a client always connects to the root of the back-end share, even after connecting to a lower-level share at the front-end. You can use the <a href="#">show cifs-service subshares</a> command to view all filer subshares corresponding to each front-end subshare.</p> <p>As an alternative to <a href="#">export ... filer-subshares</a>, you can use <a href="#">sync subshares from-namespace</a> to export all back-end subshares at once.</p>                                                                                                                                                                                                |

**Guidelines: Exporting  
from Multiple  
Namespaces**

If you share out volumes from more than one namespace, the following configuration options must match in all namespaces:

- same set of [cifs authentication](#) protocols,
- same setting for [cifs anonymous-access](#) ,
- same [ntlm-auth-server \(gbl-ns\)](#) or servers,
- same [ntlm-auth-db \(gbl-ns\)](#),
- same set of [windows-mgmt-auth \(gbl-ns\)](#) (WMA) groups, and
- same [sam-reference](#) filer for all the namespaces behind the service. This SAM-reference filer must define all local groups for all filers behind all namespaces. (The CIFS service does not strictly enforce this restriction.)

When you use the `export` command to share a volume from a new namespace, the ARX software confirms that the new namespace is consistent with all currently-exported namespaces. If any of the above options do not match, the CLI offers the opportunity to synchronize the namespace settings. Enter **yes** to proceed. This provides all backing namespaces with the same superset of options; for example, if one namespace supported Kerberos and the other supported Kerberos and NTLM, the synchronization process would configure all namespaces to have both Kerberos and NTLM.

**Guidelines:  
Unsupported  
Windows File-System  
Features**

Microsoft Windows supports several file-system features that are not supported by an ARX CIFS export. Included among these unsupported features are:

- Encryption
- Disk Quotas
- Mount Points
- Hard Links
- Distributed Link Tracking
- Change Journals
- System ACLs (SACLs), used for auditing and access alarms - an ARX CIFS service does not copy a SACL when migrating a file or striping a directory.
- OS/2 Extended Attributes (EAs)
- Object ids
- Reparse points

---

**Samples** `bstnA(gbl-cifs[www.medarcv.com])# export medarcv /rcrds description "clerical records"`  
shares the “/rcrds” volume of the medarcv namespace.

`bstnA(gbl-cifs[www.myco.com])# export homes /lhome as HOMEDIRS`  
`bstnA(gbl-cifs[www.myco.com])# export homes /lhome as ALLSHARES`  
shares the “/lhome” volume under two different share names.

`bstnA(gbl-cifs[www.myco.com])# no export as ALLSHARES`  
removes one of the shares for the “/lhome” volume. The other share name (HOMEDIRS, above) is still accessible to clients.

`bstnA(gbl-cifs[www.medarcv.com])# no export medarcv /schedules`  
stops sharing the “/schedules” volume of the medarcv namespace.

`bstnA(gbl-cifs[www.medarcv.com])# export medarcv /rcrds/2004 as Y2004 filer-subshare`  
exports a subshare behind the “/rcrds” volume, “Y2004.”

`bstnA(gbl-cifs[www.medarcv.com])# export medarcv /rcrds/VIP_wing as CELEBS filer-subshare hidden`  
exports a hidden subshare behind the “/rcrds” volume, “CELEBS\$,” but exports it as “CELEBS” so that front-end clients can see it.

| <b>Syntax</b>                                                  | <pre><b>export</b> <i>namespace</i> <i>vol-path</i> [<b>as</b> <i>export-path</i>] [<b>access-list</b> <i>name</i>]<br/><b>no export</b> <i>namespace</i> <i>vol-path</i><br/><b>no export</b> <b>as</b> <i>export-path</i></pre> <p><i>namespace</i> (1-30 characters) can be any namespace that supports NFS. If the same NFS service exports more than one namespace, all of the namespaces behind the service must have the same <a href="#">character-encoding nfs</a> settings.</p> <p><i>vol-path</i> (1-1024 characters) is the path to one of the namespace's managed volumes (for example, <code>/var</code>) or inside the volume (<code>/var/log/archive</code>).</p> <p><b>as export-path</b> (optional, 1-1024 characters) sets an advertised path to the NFS-share mount point. If entered, NFS clients see this path as an available export or share instead of the <i>volume</i> path. You cannot export the same <i>vol-path</i> under more than one name; you can only use this option to change the export path that is visible to clients.</p> <p><b>access-list name</b> (optional, 1-64 characters) is the access list to associate with this share. Use the <a href="#">show nfs-access-list</a> command to view the configured access lists.</p> |
| <b>Default(s)</b>                                              | <b>as export-path</b> , if omitted, defaults to the name of the <i>volume</i> .<br><b>access-list name</b> , if omitted, defaults to allowing all clients access to the volume/share with read/write permission, root-squash enabled, and root squashed to UID 65534 and GID 65534.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Guidelines</b>                                              | This command exports a volume from any namespace. Clients can mount this volume through NFS by accessing the virtual-IP (VIP) address of the global server's <a href="#">virtual server</a> .<br>You can enter this command multiple times to export multiple volumes.<br>You must enable the NFS service for any shares to be visible to clients. Use the <a href="#">enable (gbl-cifs, gbl-nfs)</a> command in <code>gbl-nfs</code> mode to enable NFS service.<br>If you export volumes from more than one namespace, the <a href="#">character-encoding nfs</a> settings must match in all namespaces:<br>Before you remove a volume with <code>no export</code> , you must first disable it using the <code>no enable</code> command in <code>gbl-nfs</code> mode (see <a href="#">enable (gbl-cifs, gbl-nfs)</a> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines: Behavior When a Back-End Filer Goes Offline</b> | If any filer goes offline behind this export, a client cannot access its files or directories. The NFS service could return an access error to the client (typically preferred by human users), or the service could let the client retry until the filer answers (often preferred by scripted clients). You can use the <a href="#">offline-behavior</a> command to choose the behavior of this export when a back-end filer goes offline. You can define a default behavior for the entire NFS service, and you can redefine the behavior for each export.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Sample** `bstnA(gbl-nfs[ac1.medarch.org])# export wwmed /acct`  
exports the “/acct” volume of the wwmed namespace.

**Related Commands** [nfs](#)  
[enable \(gbl-cifs, gbl-nfs\)](#)  
[offline-behavior](#)  
[show nfs-access-list](#)

## export offline-access

**Purpose** When a Windows client uses *offline access* for a file on a remote CIFS share, Windows creates a local copy of the file for the client. The client can use that local copy whenever the client machine is disconnected from the CIFS share, and can later *sync* the local copy with the original whenever the CIFS-share connection is up.

By default, clients can manually select directories and files for offline access. You can use the **export offline-access** command to also automatically enable offline access for any file the client opens (with or without network optimization), or to disable all offline access.

Use the **no** form of the command to revert to the default setting.

**Mode** gbl-cifs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **export offline-access *share-name* {manual|auto|auto-local|none}**  
**no export offline-access *share-name***

*share-name* (1-1024 characters) is the name of a share or subshare from this CIFS service, established with the **export (gbl-cifs)** command. You can use **show cifs-service fqdn** for a list of all shares and subshares in the *fqdn* service.

**manual | auto | auto-local | none** is a required choice. This maps to the offline settings in the MMC interface for managing CIFS shares. Use this command in place of those options:

**manual** means that clients must set the option for offline files and directories themselves. This maps to the MMC option (in Windows 7), “Only the files and programs that users specify are offline.”

**auto** indicates that client software is allowed to automatically enable offline access for every file the client opens. Client software is also allowed to automatically sync its local files with the files on the CIFS share whenever the connection is up. This can produce a great deal of network traffic between clients, the ARX, and the back-end filers behind this CIFS share. It maps to the Windows 7 MMC option, “All files and programs that users open from the shared folder are automatically available offline.”

**auto-local** extends the **auto** feature. This maps to the same MMC option above together with an additional “Optimized for performance” option. This permits the client software to reduce its network usage by downloading all executable files immediately after connecting. For newer Windows clients, this is equivalent to the **auto** feature.

**none** means that the client software is not permitted to offer any offline-access options to the client. This maps to the MMC option, “No files or programs from the shared folder are available offline.”

**no export offline-access *share-name*** is equivalent to **export offline-access *share-name* manual**.

**Default(s)** manual

**Guidelines** The default is sufficient for most sites. Windows servers use the same default behavior for offline access.

Both of the **auto** options have the potential for creating high network traffic, since they ensure that every opened file is locally cached, and they sync local files whenever possible. The CLI prints an informational message about this if you choose either of those options. Use these options only on the advice of F5 Support.

**Samples** stkbrgA(gbl-cifs[bgh.medarch.org])# **export offline-access naumkeag auto-local**  
% INFO: Setting offline-access to automatic may result in increased traffic loads through the ARX, if users choose to cache a very large number of files.  
makes the “naumkeag” share provide automatic offline access in every directory, but also makes the client software optimize its network usage.

bstnA(gbl-cifs[ac1.medarcv.com])# **export offline-access ARCHIVES none**  
disables offline access for the “ARCHIVES” share.

**Related Commands** [cifs](#)  
[export \(gbl-cifs\)](#)  
[show cifs-service](#)

## nfs

**Purpose** Use the `nfs` command to instantiate an NFS service for a global server.  
Use the `no` form of the command to delete an instance of NFS service.

**Mode** `gbl`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `nfs fqdn`  
`no nfs fqdn`

*fqdn* (1-128 characters) is the fully-qualified domain name (for example, “www.organization.org”) for an existing global server. Use [show global server](#) to see a list of global servers.

**Default(s)** `None`

**Guidelines** This command prompts for confirmation before creating the NFS service; enter **yes** to continue. (To prevent confirmations for creating these sorts of configuration objects, use the [terminal expert](#) command.)

This places you in `gbl-nfs` mode. You must use the [export \(gbl-nfs\)](#) command to export at least one ARX volume through NFS. Optionally (while the service is disabled), you can use `no nlm enable` to disable the NFS Lock Manager (NLM) service. Once you have at least one export, you must use the [enable \(gbl-cifs, gbl-nfs\)](#) command to start the NFS service. Clients can then mount the export(s) through the global server’s virtual-IP (VIP) address (created with the [virtual server](#) command).

If any filer goes offline behind this service, a client cannot access its files or directories. The service could return an access error to the client (typically preferred by human users), or the service could let the client retry until the filer answers (often preferred by scripted clients). You can use the [offline-behavior](#) command to choose the behavior of this service when a back-end filer goes offline. You can also use the command to customize the behavior for various NFS exports.

The ARX-500 supports a maximum of 16 front-end services, and the other platforms support up to 64. This limit applies to the sum of all NFS services (created by this command) and CIFS services (created with the [cifs](#) command).

You can use [show nfs-service](#) to show the configuration of an NFS service. The [show nfs-service mounts](#) command shows all clients who are mounted to an NFS service.

**Samples** `bstnA(gbl)# nfs www.mycompany.com`  
This will create a new NFS service.

```
Create NFS service 'www.mycompany.com'? [yes/no] yes
bstnA(gbl-nfs[www.mycompany.com])#
instantiates NFS service at www.mycompany.com.
```

```
bstnA(gbl)# no nfs www.defunctcompany.com
Delete NFS service on 'www.defunctcompany.com'? [yes/no] yes
removes the NFS-service instance that was running at www.defunctcompany.com.
```

---

**Related Commands** `export (gbl-nfs)`  
`no nlm enable`  
`enable (gbl-cifs, gbl-nfs)`  
`show global server`  
`global server -> virtual server`  
`nfs-access-list`  
`show nfs-service`  
`show nfs-service mounts`

## nfs tcp timeout

**Purpose** If an NFS/TCP connection to a back-end filer times out, the NFS service disconnects from the client. Use this command to reset the timeout and change this client-side behavior; return an NFS I/O error instead of disconnecting.

Use the `no` form of this command to go back to the default timeout and behavior.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `nfs tcp timeout seconds`  
`no nfs tcp timeout`

*seconds* (5-104) is the new timeout period.

**Default(s)** 105-second timeout period  
disconnect the client on a back-end-filer timeout

**Guidelines** If a non-default timeout is set, the NFS service returns an NFSERR\_IO (NFSv2) or NFS3ERR\_IO (NFSv3) to its client. If the default timeout is set, NFS service disconnects from clients, with the expectation that they will retry.

This command sets the timeout and behavior for *all* NFS services and filers.

Use the `show nfs tcp` command to show the current timeout period and behavior.

**Samples** `bstnA(gbl)# nfs tcp timeout 90`  
sets the timeout period to 90 seconds on the current switch. If an NFS/TCP connection times out on the back end, the NFS service returns an NFS I/O error to the client instead of disconnecting.

`bstnA(gbl)# no nfs tcp timeout`  
reverts to the default timeout and behavior.

**Related Commands** `show nfs tcp`

---

## nlm enable

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Purpose</b>          | The NFS Lock Manager (NLM) manages file locks for NFS clients. While the NFS service is disabled, you can use the <code>no nlm enable</code> command to disable NLM.<br>Use the affirmative command, <code>nlm enable</code> , to enable NLM for this NFS service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Default(s)</b>       | <code>nlm enable</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>       | <p>The current NFS service must be disabled (through <code>no enable (gbl-cifs, gbl-nfs)</code>) for this command to function.</p> <p>The CLI prompts for confirmation before stopping NLM; enter <b>yes</b> to proceed.</p> <p>An NFS-client application can lock a file or a region within a file, so that other NLM-compliant applications cannot access the region until the lock is released. You can disable NLM on a service-by-service basis.</p> <p>It is often appropriate to disable NLM for a <a href="#">direct</a> volume, where clients are allowed to access back-end files without going through the ARX. Each volume manages its own set of NLM locks, unknown to any of the filers behind the volume. If any client accesses a file by going directly to the filer, the filer is unaware of any NLM locks that the volume may have granted. This is also true if a client accesses the same file through another direct volume. In either case, the volume behind this NFS service is incapable of enforcing its NLM locks.</p> <p>To support NLM locking for direct volumes, you must be sure that clients exclusively use the volume to access all of the direct shares behind it.</p> <p>If multiple NFS services export the same volume, consistently enable or disable NLM for all of them. This applies to managed volumes as well as direct volumes.</p> <p>To see all the client machines that hold locks for a given file, use the <a href="#">show nlm file</a> command. For a list of locks held by a given client machine (or a list of all the client machines that have locks), use the <a href="#">show nlm client</a> command. If a client machine is down, you can clear all of its locks with <a href="#">clear nlm locks</a>. Use <a href="#">show nlm statistics</a> to see statistics for all NLM activity.</p> |

## offline-behavior

**Purpose** When an NFS client attempts to access a file on an offline filer, the ARX-NFS service ignores the request and lets the client retry; this can block the NFS client for a long time. Use the `offline-behavior ... deny-access` command to immediately return an access error (typically `NFSERR_ACCES` or `NFS3ERR_ACCES`) instead. This provides a definitive answer to NFS-client software, so that it can return an error for an offline file and immediately move on to other file requests.

To silently wait for a client retry instead of returning an access error, use the `offline-behavior ... retry` command. This setting prevents sparse returns (a mixture of available files and access errors) for multi-file requests.

Use the `no offline-behavior` command to revert to the inherited offline behavior for the entire NFS service, one namespace behind the service, one volume behind it, or one particular export from one of its volumes.

**Mode** gbl-nfs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `offline-behavior [namespace ns [volume /vol [path expt-path]]] { retry | deny-access }`  
`no offline-behavior [namespace ns [volume /vol [path expt-path]]]`

*ns* (optional, 1-30 characters) narrows the scope of this command to a particular namespace behind this NFS service.

*/vol* (optional if you choose namespace, 1-1024 characters) narrows the scope further, to a particular volume in the above namespace.

*expt-path* (optional, if you choose a volume, 1-64 characters) narrows the scope to one explicitly-exported path in the volume. You must choose an export path that is explicitly exported with the `export (gbl-nfs)` command. The command is accepted, but the NFS service does not honor the offline behavior until someone exports this exact path.

**retry** | **deny-access** is a required choice:

**retry** causes the service to accept requests to offline filers without sending an error back to the NFS client. The client must therefore retry until the filer comes back online, or until the client software times out. This causes NFS requests to hang if they involve a mix of online and offline filers.

**deny-access** causes the service to return an error (typically `NFSERR_ACCES` or `NFS3ERR_ACCES`) for any client request that requires an offline filer. An NFS request succeeds (with some access errors) if it accesses both online and offline filers.

**no offline-behavior** reverts to the behavior inherited from the parent path, volume, namespace, or NFS service. Inheritance is explained below.

**Default(s)** `no offline-behavior`

At the NFS-service level, this is equivalent to `offline-behavior retry`.

**Guidelines** If one filer fails behind an NFS service on the ARX, only a subset of the service's files are unavailable. Clients may prefer to work with the subset of files instead of waiting until all files are available again. By default, the ARX service drops all requests to offline filers: soft-mounted clients retransmit the request until they time out, and hard-mounted clients retransmit indefinitely. You can use this command to make the ARX service return errors to its clients instead of allowing them to retry.

For multi-file requests, this behavior can result in sparse returns (a mixture of access errors and available files).

For example, suppose an NFS client mounts an ARX export with one offline filer and runs the Unix `ls -l` command. If the export is configured to `deny-access` for offline files, the user would see access errors in place of the offline files (two of them, in this case), along with full information for all of the accessible files:

```
juser@client2:/mnt/arx$ ls -l
ls: process.html: Permission denied
ls: time.html: Permission denied
total 160
drwxrwxrwx 11 juser engineering 4096 2009-08-31 10:52 acctProcs
-rwxrwxrwx 1 muser medteam 9927 2006-04-11 22:19 ctrlProc.html
drwxrwxrwx 2 muser medteam 4096 2006-03-22 10:07 images
-rwxrwxrwx 1 xuser srnurses 2058 2006-03-26 21:07 index.html
-rwxrwxrwx 1 juser engineering 1743 2006-03-22 10:17 intro.html
drwxrwxrwx 3 muser medteam 4096 2009-08-24 16:01 payable
-rwxrwxrwx 1 muser medteam 20326 2005-05-06 09:31
timeSheetForm.xsl
juser@client2:/mnt/arx$...
```

For an ARX export that waits for the client to `retry`, the above command would hang until the back-end filer came back online or the `ls` command timed out.

**Guidelines: Retry vs.  
Deny-Access  
Behavior**

For volumes where an NFS client desires access to some filers whether or not other filers are available, we recommend the `deny-access` behavior. This behavior always allows NFS access to filers that are online, even for directories that are partially hosted by an offline filer. This can be useful in tiered volumes where files on the lower-tier filers are rarely accessed.

**Guidelines:  
Offline-Behavior  
Inheritance**

The best practice is to choose a general rule for the NFS service (either clients want access to a subset of files when a filer is offline, or they would prefer no access if any filer is offline), and apply the opposite rule to specific NFS exports where you want the opposite behavior. An NFS export inherits its offline behavior as follows:

- NFS-service
- namespace
- volume
- export path
- export sub path

For example, suppose a service hosts a software repository, and is mostly used by scripts that build the software into executable files. If any files are missing from the build, the build would fail. The default for this service should therefore be

```
offline-behavior retry
```

to support the build scripts. If any filer is offline, the build should wait for it to come back online before it continues.

Suppose that one of its exports was used by engineers for collecting the executable output files and copying them to test environments; that particular export could override the service's offline behavior. The engineers would likely prefer to see all the available files even when some are unavailable. If the export was "/usr/local/bin" in the "eng~/builds" volume, you could use

```
offline-behavior namespace eng volume /builds path /usr/local/bin
deny-access
```

in the same NFS service. The second command changes the offline behavior for the /usr/local/bin export only.

For a sub-export that is used by other scripts, you could set the offline behavior at that export level. For example,

```
offline-behavior namespace eng volume /builds path
/usr/local/bin/auto-drop retry
```

sets the retry behavior for an export under /usr/local/bin.

**Guidelines: Offline  
Behavior Applies to  
Exact Export Paths**

The offline behavior setting is only useful if there is an [export \(gbl-nfs\)](#) for the exact path named in the `offline-behavior` command. The above examples would be ineffective until someone also issued both of the following `export` commands:

```
export eng /builds/usr/local/bin
export eng /builds/usr/local/bin/auto-drop
```

If /usr/local/bin was exported but not /usr/local/bin/auto-drop/, an NFS client that mounts /usr/local/bin/auto-drop would get the offline behavior for /usr/local/bin, "deny access." You can use the [show nfs-service ... detailed](#) command to confirm that all of your offline behavior settings are assigned to at least one NFS export.

**Samples** `bstnA(gbl-nfs[ac1.medarch.org])# offline-behavior deny-access`  
causes the “ac1.medarch.org” service to return an access error to NFS clients who access an offline filer. Presumably, the service has predominantly human clients who do not require access to all files in the volume all the time.

```
bstnA(gbl-nfs[ac1.medarch.org])# offline-behavior namespace wmed
volume /acct path /wksheets retry
```

% WARNING: This command did not match any existing export. It will have no effect until an export matching '/acct/wksheets' is entered in this NFS service.

overrides this default behavior for clients that connect to the /acct/wksheets export. The warning indicates that the export does not yet exist, so NFS clients that mount /acct/wksheets still get the access errors for offline filers. You can use the [export \(gbl-nfs\)](#) command to create the /acct/wksheets export later, and that export would then get the `retry` behavior.

```
bstnA(gbl-nfs[ac1.medarch.org])# offline-behavior namespace insur retry
```

sets the retry behavior for exports from the 'insur' namespace. As above, this overrides the default set for the NFS service.

**Related Commands** [nfs](#)  
[export \(gbl-nfs\)](#)  
[show nfs-service](#)

---

# probe delegate-to

**Purpose** A front-end CIFS service can delegate CIFS to the filers behind it. A CIFS client can then authenticate once and access any of the service's back-end filers without re-authenticating. This single-authentication mechanism, facilitated by *constrained delegation*, requires some configuration at the local DC. After the CIFS service joins its domain using constrained delegation (with [domain-join](#)), you must go to the DC and inform it of the filers to which the CIFS service can delegate. This command lists all of the filers behind a given CIFS service, along with their current delegation status. You can use this list to confirm that all filers are correctly set at the DC.

**Mode** priv-exec

**Security Role(s)** crypto-officer or storage-engineer

**Syntax** `probe delegate-to fqdn [user user-name domain domain-name]`

*fqdn* (1-128 characters) is the fully-qualified domain name for a CIFS service (for example, "www.organization.org").

`user user-name domain domain-name` (optional) is a Windows-user identity for the probe operation. The CLI uses this Windows identity to test whether or not the CIFS service can delegate to each back-end filer. If you omit this, the CLI uses the [proxy-user \(gbl-ns\)](#) from one of the namespaces behind the CIFS service.

*user-name* and

*domain-name* each take 1-128 characters.

**Guidelines** This command is only relevant for a CIFS service with constrained delegation. You set up constrained delegation at a DC or with the [domain-join](#) command. A background query runs every 10 minutes to confirm that the service has constrained delegation; this command does not function until that query runs successfully at least once.

You can use this command to find all of the filers behind a given CIFS service. At the DC, you can apply each of these filers in the **Delegation** list for the CIFS service: select the "Trust ... for delegation for specified services" and the "Use any authentication protocol" flags, then add the filers to the list of services. The CIFS service must be allowed to delegate to all of these filers so that its clients can authenticate to them. The client-authentication mechanism can then be any combination of NTLM, NTLMv2, and Kerberos.

Once the service is properly configured at your DCs, you can use this command to confirm the configuration.

**Guidelines (Cont.)** The output displays the exact username and domain used for the probe, followed by a table of probe results. The table contains one sub table per filer behind the CIFS service. Each sub table contains the following rows:

**External-Filer** is the name of the back-end filer. You can use the [show external-filer](#) command to list all external filers on the ARX.

**Filer SPN** is the service-principal name (SPN) of the back-end filer. This is the SPN that the ARX discovered, or the one that was set with the [spn](#) command. The next two SPNs are both expected to be on the CIFS service's **Delegation** list, at the DC.

**Probe SPN-1** is another service-principal name (SPN) for the back-end filer. This is the exact text of a SPN that someone must enter at the DC. After the SPN is the status of that SPN on the DC:

OK means that the DC allows the front-end CIFS service to delegate to this SPN. If **Probe SPN-1** and **Probe SPN-2** both have this status, the filer is properly entered in the CIFS service's **Delegation** (or "delegate-to") list.

**Failed (Not in delegate-to list)** means that the front-end CIFS service cannot delegate to this filer. Go to one of the DCs for the service's domain and add this filer to the **Delegate** list for the CIFS service. Use the full filer name from this **Probe SPN** field. Configure the CIFS service to delegate "cifs" to the filer.

**Failed (Filer spn is not configured nor discovered)** indicates that the filer's service principal name (SPN) is unknown. You can use [show exports](#) to automatically discover a filer's SPN, or [spn](#) to manually set it.

**Failed (Filer not in the same domain)** means that the back-end filer is not joined to the same domain as the CIFS service. The CIFS service belongs to the Windows domain of its backing namespace(s): use [show cifs-service cifs-service](#) to find this Windows domain for a given *cifs-service*. The filer must be joined to the same Windows Domain for constrained delegation to function.

**Probe SPN-2** is the exact text of a second SPN that should be on the CIFS service's **Delegation** (or "delegate-to") list. As above, the SPN's status appears after the SPN. If either SPN fails, address the issue as described above.

**Samples** `bstnA# probe delegate-to ac1.medarch.org user juser domain MEDARCH.ORG` uses an identity of "juser@MEDARCH.ORG" to test the CIFS delegation for the "insur.medarch.org" service. See [Figure 24.1 on page 24-41](#) for sample output. In this case, neither of the service's back-end filers are on its **Delegation** list, so the administrator must go to a local DC to add them.

`stoweA# probe delegate-to patrol.MEDARCH.ORG` tests the delegation status for the "patrol.MEDARCH.ORG" service. This uses the credentials defined for the proxy-user in one of the service's backing namespaces; those credentials appear at the top of the output. For sample output, see [Figure 24.2 on page 24-41](#). This service is properly configured at the DCs.

# remove namespace ... volume ... exports-only

**Purpose** Use the `remove namespace ... volume ... exports-only` command to remove all of a volume's front-end exports.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `remove namespace name volume volume exports-only [timeout seconds] [sync]`

*name* (1-30 characters) identifies the namespace.

*volume* (optional, 1-1024 characters) focuses on a single volume.

**exports-only** removes all front-end exports (created with [export \(gbl-nfs\)](#) and/or [export \(gbl-cifs\)](#)) for the specified volume. The volume and namespace configurations remain.

**seconds** (optional, 300-10,000) sets a time limit for each component operation in the removal process.

**sync** (optional) shows its progress at the command line. With this option, the CLI prompt does not return until all components have been removed.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before removing any front-end exports; enter **yes** to proceed.

By default, this command generates a report to show all of the actions it takes to remove the volume(s), in order. The CLI shows the report name after you issue the command, and then returns. You can enter CLI commands as the namespace software removes the exports in the background. Use [tail](#) to follow the report as it is written. Use [show reports file-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the `copy` or `delete` commands. Use the `sync` option to send the status to the command line instead; the command does not generate a report if you use the `sync` option.

Use [remove namespace](#) to remove an entire namespace or volume, or [remove service](#) to remove an entire namespace and *all* configuration objects that are dedicated to the namespace (including the front-end exports). To remove a share from a volume, use [remove-share migrate](#) or [remove-share nomigrate](#).

**Sample**

```
prtlnDA# remove namespace insur_bkup volume /insurShdw exports-only
```

```
Remove exports for namespace 'insur_bkup', volume '/insurShdw'?
[yes/no] yes
Scheduling report: removeNs_insur_bkup_200605250803.rpt
removes all front-end exports for the "insur_bkup~/insurShdw" volume.
```

**Related Commands** [remove namespace](#)  
[remove service](#)  
[remove-share migrate](#)  
[remove-share nomigrate](#)

## show cifs-service

**Purpose** Use the `show cifs-service` command to display configuration information about front-end CIFS service(s).

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show cifs-service [{ fqdn | all } [detailed]]`

*fqdn* (optional; 1-128 characters) is the fully-qualified domain name for one CIFS service (for example, “www.organization.org”).

**all** (optional) shows summaries of all CIFS-service offerings.

**detailed** (optional) adds CIFS-share details to the output.

If you enter the command without any of these options, the output is a table of CIFS services.

**Guidelines** The default output is a table of all CIFS services, one service per row, with the following columns:

**Service Name** is the FQDN that identifies the CIFS service. The `cifs` command, which instantiates the CIFS service, establishes this FQDN. It is the same as the FQDN for the `global server` where this service runs.

**Description** is set by the `description (gbl-cifs)` command.

**Guidelines: Output for Each Service**

If you focus on a single CIFS service, more details appear. Several of these fields are updated by a background query to the DCs. This background query runs every 10 minutes, so you cannot immediately see the results of a [domain-join](#) operation:

**Service Name** is described above.

**Domain Join** shows whether or not the CIFS service has performed a successful [domain-join](#) operation.

- **Joined to *domain-name*** indicates that the CIFS service has successfully joined the given domain.
- **Not Joined** indicates that the domain-join operation failed, or that no-one ever ran the command for this service.

This field is updated by the DC query mentioned above. It can take up to 10 minutes after a [domain-join](#) for this output to show the results of the operation.

**Account Name** the name that was used for the machine account at the local DCs. This is typically the hostname part of the CIFS-service FQDN followed by a “\$” symbol; for example, “insur\$” could be the account name for the “insur.medarch.com” service. If that hostname exceeds 15 bytes, this is the first 15 bytes of the hostname followed by a “\$” (for example, the account name for “reallylonghostname.myorg.org” would be “reallylonghostn\$”). As above, this field is updated by a DC query that runs every 10 minutes.

**Delegation** is the machine account’s setting for the “Trust for delegation” flag at the DCs. This determines whether or not the DCs trust the CIFS service to delegate CIFS access to its filers.

- **Constrained, Any Protocol** indicates that this CIFS service is trusted to delegate its CIFS service to a limited number of filers (listed in the next field).
- **Unconstrained, Kerberos Only** means that this CIFS service is trusted to delegate any CIFS-related service to any filer. Clients cannot authenticate with NTLM or NTLMv2 unless you assign an [ntlm-auth-server \(gbl-ns\)](#) or an [ntlm-auth-db \(gbl-ns\)](#) to the namespace behind the service.
- **None** indicates that this CIFS service is not trusted to delegate any service to any filer. CIFS clients cannot access any of the storage behind this service. To correct this issue, an administrator with sufficient credentials must access the service’s computer account at a local DC and raise its “Trust for delegation” flag. The account name appears in the field above.
- **Not Applicable** means that the domain-join operation failed, or that no-one ever ran the [domain-join](#) command for this service.

As above, this field is updated by a DC query that runs every 10 minutes.

**Delegate To** shows a list of filers to whom the CIFS service is allowed to delegate. This is “Not Applicable” until someone performs a successful [domain-join](#) for the CIFS service. This list is only relevant if the **Delegation** type (above) is **Constrained**. Each filer appears on a separate line, in the format “cifs/*filer-name*.” The “cifs/” string indicates that the service can delegate “CIFS” to the filer; if another service type appears here, the line is irrelevant. If no filers appear here and the **Delegation** is **Constrained**, an administrator with sufficient credentials must access the service’s computer account at a local DC and add them. The DCs must trust the CIFS service to delegate CIFS to all the filers behind it. You can use [probe delegate-to](#) to get a complete list of the CIFS filers behind the CIFS service. As above, this field is updated by a DC query that runs every 10 minutes.

**Guidelines: Output for  
Each Service (Cont.)**

Description, is described for the summary output, above.

State is Enabled or Disabled, as set by the [enable \(gbl-cifs, gbl-nfs\)](#) command.

Signatures describes this service's setting for SMB signing, a CIFS security feature. This is **Enabled** (use SMB signing if and only if the client requires it), **Required** (only allow connections from clients that agree to use SMB signing), or **Not Enabled** (only allow connections from clients that do *not* require SMB signing). You can change this with the [signatures](#) command.

WINS Name Encoding is the character-encoding method used for the service's WINS-name registration. If the service uses WINS for name resolution, this is the character encoding used to send the CIFS service's name to the WINS server.

You can use the [wins-name-encoding](#) command to change this.

Then there are sub-tables with the service's CIFS shares. Each sub table shows the shares from one namespace:

Exports for Namespace: *ns-name* identifies one namespace behind this CIFS service. The [export \(gbl-cifs\)](#) command establishes a namespace for the service.

Share Name is the name that is advertised to clients.

S appears for *subshares* of an imported share. To configure a subshare for this service, use the *filer-subshare* argument in the [export \(gbl-cifs\)](#) command, or use [sync subshares from-namespace](#).

Volume Path is the directory path that is being shared, set by the [export \(gbl-cifs\)](#) command.

State describes the state of the volume behind this share:

- **Online** indicates that the volume is operational.
- **Degraded**: At least one of the volume's shares is offline, and at least one share is online. CIFS clients can only access the files and directories on the online share(s).
- **Offline**: All shares in the backing volume are disabled or unreachable. CIFS clients cannot access the front-end share.
- **Read-Only**: CIFS clients cannot write to this volume because it was enabled with **no modify** set. If the volume has no import issues, you can go to *gbl-ns-vol* mode and use [modify](#) to allow clients to write.
- **Unavail**: Some or all backing shares are enabled, but the volume is not starting or stopping. An attempt to map to this share may time out.
- **Snapshot**: The share is an export of the *~snapshot* directory (or its equivalent; you can set the directory name with the [snapshot directory cifs-name](#) and/or [snapshot directory nfs-name](#) commands). This is a virtual directory created and presented by the volume software.
- **Not Found**: The Directory named in the export does not exist.

**Degraded** (at the end of the row) only appears for a CIFS subshare. This indicates that the filer subshares behind this client-visible subshare are not replicated properly. All of the filer subshares must have the same name (or a special name generated by the ARX), the same directory path (relative to the root of each filer share), and the same ACL. If this flag appears for any subshare, the CLI provides a prompt at the bottom suggesting that you use [sync subshares from-service ... tentative](#) to get details about the problem.

**Guidelines: Detailed Output**

Detailed output displays the same configuration and state fields for each CIFS service, followed by a separate table for each of the service's CIFS shares. Each share table has the following fields:

(The name of the share is the header.)

**Namespace** is the ARX namespace that holds the share's storage.

**Volume Path** is the ARX volume in the above namespace.

**Description** is set by an option in the [export \(gbl-cifs\)](#) command.

**Export state** describes the state of the client-side export. This often depends on the results of the subshare-replication process that occurs during managed-volume import. If the backing volume contains any CIFS subshares, the volume must replicate all subshare definitions on all of its filers:

- **Ready:** Clients can use the share or subshare. This indicates that the subshare replication process succeeded, or that there are no subshares under this share.
- **Idle:** The CIFS service is not-yet enabled, so clients cannot connect (or map a drive) to it. You can use [enable \(gbl-cifs, gbl-nfs\)](#) to enable the CIFS service.
- **Pending:** This only appears for a CIFS subshare. The subshare and its ACL is currently being replicated at all back-end filers behind the volume.
- **NSM Wait:** Subshare replication has completed successfully for the backing volume, and the service is now programming the volume's shares and subshares on the network (NSM) processors.
- **Degraded:** This only appears for a CIFS subshare. At least one of the filer subshares for this front-end subshare failed to replicate properly. That is, one of the back-end filers does not have the same subshare name and/or ACL. CIFS clients can only access the files and directories on the replicated subshare(s). As mentioned above, you can use the [sync subshares from-service ... tentative](#) command to get details about the problem.
- **Unknown:** Contact F5 Support if this status appears in the output.

**Path State** is the same as the **State** field in the summary output, described above.

**Filer-subshare** is Yes or No, depending on whether or not the share is implemented as a subshare. To create a subshare, use the **filer-subshare** argument in the [export \(gbl-cifs\)](#) command, or use [sync subshares from-namespace](#) to export all subshares from a particular backing volume.

**Offline-access** shows the type of offline access allowed to the share's clients. Clients can use this feature to make a local copy of a file on this share, edit the copy while disconnected from the share, then sync the copy with the original on the share once the connection is re-established. This shows the value set by the [export offline-access](#) command on the current share.

**Samples** `bstnA> show cifs-service`  
lists all global servers (by their FQDNs) configured with a CIFS front-end service. See [Figure 24.3 on page 24-48](#) for sample output.

`bstnA> show cifs-service ac1.medarch.org`  
shows a summary for the CIFS service running at “ac1.medarch.org.” For sample output, see [Figure 24.4 on page 24-48](#).

`bstnA> show cifs-service all`  
shows summaries for all the front-end CIFS services on the “bstnA” chassis. See [Figure 24.5 on page 24-49](#) for sample output.

`stoweA> show cifs-service patrol.MEDARCH.ORG detailed`  
shows details for the CIFS service at “patrol.MEDARCH.ORG.” For sample output, see [Figure 24.6 on page 24-50](#).

## show cifs-service subshares

**Purpose** A *subshare* is a CIFS share of another CIFS share's subdirectory. You can configure a volume to pass CIFS clients from a front-end subshare directly to the corresponding subshare on the back-end, therefore applying the correct share-level ACL for the client's access. Use the `show cifs-service subshare` command to show the mapping of front-end subshares to their corresponding back-end subshares.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show cifs-service subshares {fqdn|all} [detailed]  
[state {ready | degraded | idle | pending | nsmwait}]`

*fqdn|all* chooses one (or all) CIFS services:

*fqdn* (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, "www.mycharity.org").

**all** shows the subshares in all CIFS services.

**detailed** (optional) expands the output to show details for each subshare.

**state {ready | degraded | idle | pending | nsmwait}** (optional) filters the output so that it shows only the subshares in the specified state. The *Guidelines* below explain each of these states in detail.

**Guidelines: Summary Output** The summary output is one table for each CIFS service. Each table is labeled with the following field:

**Service** is the FQDN that identifies the CIFS service. The `cifs` command, which instantiates the CIFS service, establishes this FQDN. It is the same as the FQDN for the `global server` where this service runs.

The table contains one filer subshare per row. The filer subshares are grouped together with their front-end exports. Each row contains the following fields:

**Export** is the name of the front-end subshare, seen by clients of the CIFS service. The `export (gbl-cifs) ... filer-subshare` command establishes this name.

**Filer** is the name of an external filer that hosts a back-end subshare. This is the external-filer name defined in the ARX configuration; use `show external-filer` to see a full list of external filers.

**Share** is the name of the parent share at the back-end filer.

**Subshare** is the name of the subshare at the back-end filer. Some subshares that are automatically generated by the ARX (with `filer-subshares`, `sync subshares from-namespace`, or `sync subshares from-service`) may have names with the following format: "\_acopia\_subshare\_id\$," where *subshare* is the name of the original subshare and *id* is a unique integer to identify the replica. If the subshare synchronization is underway and the back-end subshare is temporarily inaccessible to clients, the term [Fenced] appears in place of the subshare name.

**Guidelines: Summary Output (Cont.)**

**State** describes the results of the subshare-replication process that occurs during managed-volume import. If the backing volume contains any CIFS subshares, the volume must replicate all subshare definitions on all of its filers:

- **Ready:** This indicates that the subshare replication process succeeded, or that there are no subshares under this share.
- **Idle:** The CIFS service is not-yet enabled, so clients cannot connect (or map a drive) to it. You can use [enable \(gbl-cifs, gbl-nfs\)](#) to enable the CIFS service.
- **Pending:** This only appears for a CIFS subshare. The subshare and its ACL is currently being replicated at all back-end filers behind the volume.
- **NSM Wait:** Subshare replication has completed successfully for the backing volume, and the service is now programming the volume’s shares and subshares on the network (NSM) processors.
- **Degraded:** This only appears for a CIFS subshare. At least one of the filer subshares for this front-end subshare failed to replicate properly. That is, one of the back-end filers does not have the same subshare name and/or ACL. CIFS clients can only access the files and directories on the replicated subshare(s). As mentioned above, you can use the [sync subshares from-service ... tentative](#) command to get details about the problem.
- **Unknown:** Contact F5 Support if this status appears in the output.

**Guidelines: Detailed Output**

If you used the detailed flag in any command, the output contains a complete table for each subshare:

**Export** is the name of the CIFS service’s subshare, as seen by CIFS clients.

This table contains one sub table per back-end instance of the subshare. Each sub table contains the following fields:

**Filer** is the name of the back-end filer, as configured on the ARX. For details on this filer (such as its IP address), use the [show external-filer filer-name](#) command.

**Share** is the name of the imported share on the filer. The subshare resides in this share.

**Subshare** is the name of the subshare on the filer. This is described above.

**State** is also described above.

**Samples**

```
bstnA> show cifs-service subshares ac1.medarch.org
```

shows all of the front-end subshares in the “ac1.medarch.org” service, and all of the back-end subshares that correspond with them. The sample in [Figure 24.7](#) shows several front-end subshares, where each is connected to three back-end subshares.

```
bstnA> show cifs-service subshares ac1.medarch.org detailed
```

shows details for the above subshares. [Figure 24.7](#) shows sample output.

```
canbyA> show cifs-service subshares all state degraded
```

No CIFS subshare mappings.

shows all degraded subshares on the “canbyA” chassis. None of the subshares on this system are in the “degraded” state.

## show dynamic-dns

**Purpose** A CIFS service can use dynamic DNS to register its host name(s) and VIP with the local DNS server. Up-to-date DNS information is required for Kerberos authentication. To display the configuration and current status of all dynamic-DNS connections, use the `show dynamic-dns` command.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show dynamic-dns [fqdn]`

*fqdn* (optional; 1-128 characters) is the fully-qualified domain name for one CIFS service (for example, “www.organization.org”). If you omit the FQDN, this command shows DNS summaries for all CIFS services.

**Guidelines** For every CIFS service that uses dynamic DNS, the output contains one table with a summary for the service and a sub-table with one row per DNS alias. The first table contains three fields:

**Svc** is the type of front-end service. This is always “CIFS” in the current implementation.

**Global Server** identifies the [global server](#) for the CIFS service. The `cifs` service uses the same name.

**Domain Name** is the [windows-domain \(gbl-gs\)](#) for the Global Server. This is also the Windows domain for the CIFS service.

Each CIFS-service table has a sub-table of its host names:

**Status** is one of the following values:

- “OK” indicates that the CIFS service successfully added this host name.
- “Retry” means none of the DNS [name-servers](#) acknowledged the add or remove operation. (The operation type, add or remove, is shown in the **Operation** field.) The CIFS service retries once per minute.
- “Failed” indicates that a remove operation failed. It retries an add operation forever, but only retries a remove operation 15 times. You must remove the “A” record manually at the DNS server itself. Any Failed removes remain in this output until you clear them all (system-wide) with [clear dynamic-dns](#).
- “Disabled” means the CIFS service is disabled (with `no enable (gbl-cifs, gbl-nfs)`) and therefore is not adding or removing any records from DNS.
- “Pending” indicates that the operation has started but is incomplete for this host name; another host name is in process. This state should change quickly to one of the other states.

**Host Name** is a host name that was configured for this CIFS service, set by the [dynamic-dns](#) command.

**VIP** is the virtual-IP address for this CIFS service, set by the `gbl-gs-vs virtual server` command. The CIFS service registers the **Host Name** with the **VIP** in a single “A” record.

**Guidelines (Cont.)**

Operation is “add” or “remove.” The `dynamic-dns` command triggers an add operation. A remove is triggered by commands that delete a DNS host name (`no dynamic-dns`) or change the VIP (`virtual server`). This field is empty if the CIFS service is disabled.

Retries is the number of failed attempts to register the host name. This should be 0 (zero); if it is greater than 0, you should check the DNS server(s) that are configured for the domain. (The `name-server` command configures one DNS server for an Active-Directory domain.) The syslog catalogs all registration failures; use `show logs syslog` to view the syslog. As above, this field is empty if the CIFS service is disabled.

Last Update is the time and date of the last attempt to register this host name.

DNS Server is the IP address of the `name-server` where the Last Update was sent. If the Status is “FAIL,” this server may be down. If the Status is “OK” but the Retries are 1 or more, the registration failed at some other DNS server(s) before it succeeded at this one.

**Sample** `bstnA> show dynamic-dns ac1.medarch.org`

shows the current status of dynamic DNS for one CIFS front-end service. See [Figure 24.9 on page 24-57](#).

**Related Commands** `dynamic-dns`  
`clear dynamic-dns`

**Figure 24.9** Sample Output: `show dynamic-dns ac1.medarch.org`

```
bstnA> show dynamic-dns ac1.medarch.org
```

## show global service

**Purpose** Use the `show global service` command to cross-reference the front-end services with their global servers.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show global service [fqdn]`

*fqdn* (optional; up to 128 characters) is the fully-qualified domain name (for example, “www.organization.org”) for one global server.

If no FQDN is specified, this command lists the front-end services for all global servers.

**Guidelines** This displays a table of front-end services, ordered by global server.

Domain Name is the FQDN that identifies the global server.

Service is the type of front-end service:

- NFS or
- CIFS

State is enabled or disabled. Use [enable \(gbl-cifs, gbl-nfs\)](#) to enable a front-end service.

**Samples** bstnA> `show global service`

| Domain Name     | Service | State   |
|-----------------|---------|---------|
| acopiaFiler     | NFS     | Enabled |
| ac1.MEDARCH.ORG | NFS     | Enabled |
| ac1.MEDARCH.ORG | CIFS    | Enabled |

shows all front-end services at all global servers.

bstnA> `show global service ac1.MEDARCH.ORG`

| Domain Name     | Service | State   |
|-----------------|---------|---------|
| ac1.MEDARCH.ORG | NFS     | Enabled |
| ac1.MEDARCH.ORG | CIFS    | Enabled |

shows the front-end services for one global server, “ac1.MEDARCH.ORG.”

**Related Commands** [show global server](#)  
[show virtual service](#)

---

## show nfs-service

**Purpose** Use the `show nfs-service` command to display configuration information about one or more front-end NFS services.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show nfs-service [fqdn | all] [detailed]`  
`show nfs-service fqdn export namespace export-path`

*fqdn* (1-128 characters) is the fully-qualified domain name (for example, “www.organization.org”) for one NFS service. If no FQDN is specified, this command shows summaries for all NFS-service offerings.

**all** (optional) shows full configurations for all NFS-service offerings.

**detailed** (optional) shows full configurations for the selected NFS service(s), along with an additional table to show the behavior of each NFS export when one of its back-end shares is offline. When a client attempts to access a file that resides on an offline share, the NFS export can either send an access error to the client or silently wait for the client to retry. You can configure this behavior with the [offline-behavior](#) command.

**export namespace export-path** focuses on a single service export. This shows the full configuration and the offline-behavior details for the selected export.

*namespace* (1-30 characters) is the namespace that hosts the export, and

*export-path* (1-1024 characters) is the full path of the NFS export, starting with the volume name.

**Guidelines: Summary View** The summary output is a table of NFS-service summaries, one row per service. The table has three columns:

**Domain Name** is the FQDN that identifies the NFS service. The [nfs](#) command, which instantiates the NFS service, establishes this FQDN. It is the same as the FQDN for the [global server](#) where this service runs.

**Description** is a string to describe this service. You can change it with the [description \(gbl-nfs\)](#) command.

**Guidelines: Full-Configuration View** The detailed output shows similar fields, followed by additional configuration details:

**Virtual Server** is the same as the **Domain Name** in the summary output; it is the FQDN that identifies the NFS service.

**Description** also matches the summary output.

**NFS State** is “Enabled” or “Disabled.” This is the administrative state, set with the [enable \(gbl-cifs, gbl-nfs\)](#) command.

**NLM State** is also “Enabled” or “Disabled.” This shows whether or not the NFS Lock Manager (NLM) protocol is running for this NFS service. You can set this with the [nlm enable](#) command.

**Guidelines:**  
**Full-Configuration**  
**View (Cont.)**

Each NFS-service table has a sub-table for each of its backing namespaces. The sub tables contain all of the NFS exports backed by the given namespace:

**Exports for Namespace** *name* is the heading for each export table. This is the namespace that holds the back-end storage for the exports below.

**Export As** is the NFS-export name that is advertised to clients. You can enter this with the [export \(gbl-nfs\)](#) command.

**Volume Path** is the managed-volume path that is being shared. You also enter this as part of the [export \(gbl-nfs\)](#) command. An asterisk (\*) appears after this if the export returns an access error for back-end shares that are offline; you can use the [offline-behavior](#) command to change this behavior.

**State** is the volume's state:

- Online
- Degraded: At least one share is offline, and at least one share is online. NFS clients may be able to access the files and directories on the online share(s).
- Offline: All shares in the volume are disabled or unreachable. If a client attempts to mount this export, the NFS service denies the mount with MNTERR\_ACCESS.
- Read-Only: NFS clients cannot write to this volume because it was enabled with no **modify** set. Go to gbl-ns-vol mode and use [modify](#) to allow clients to write.
- Unavailable: Some or all shares are enabled, but the volume is not starting or stopping. An attempt to mount this export may time out.
- Unknown
- Not Found: The **Directory** named in the export does not exist, An attempt to mount this directory fails with MNTERR\_NOENT.

**Access** shows the permissions that clients have for accessing this service. If an NFS access list is assigned to this service (with the [nfs-access-list](#) command), the name of the access list appears here. An "(rw)" appears if no access list is configured; this indicates that all clients have read and write access to the service.

**(NIS ip-address)** appears if the access list refers to at least one NIS netgroup. This is the address of the NIS server used for the most-recent NIS update. The word **ERROR** appears instead of the IP address if the netgroup is not completely resolved. The error indicates that either a netgroup has caused the access list to grow too large, or one of the hosts in one of the netgroups cannot be resolved through a DNS lookup. Use [show nis domain](#) to find more details about the NIS configuration and its current status.

**Guidelines: Detailed View**

The **Offline-behavior** table appears if you enter the **detailed** option in the command. This table shows the export behavior when clients access a back-end filer that is offline: the export either returns an access error to the client or silently allows the client to retry. The top row shows the default **offline-behavior** for the whole service, and the following rows (if any) each show the offline behavior for an individual namespace, volume, or export in the service. Each row contains the following columns:

**Namespace** is one of the namespaces behind the current NFS service. This contains “All” in the top row and a specific namespace name in all subsequent rows.

**Volume** is one volume in the namespace, or “All” if the behavior applies to all of the namespace’s volumes.

**Path** is a volume path that is exported to NFS clients, or “All” to indicate that the behavior applies to all of this volume’s exported paths.

**Behavior** is “deny-access” or “retry.” This shows the export behavior when a client accesses a file or directory on a back-end share that is currently offline. Either the client receives an access error or the NFS service silently waits for the client to retry the request.

**Count** shows the number of NFS exports that use this behavior. If the count is 0 (zero) for a given behavior row, there is no export with the exact **Path** in this row. You can use the `show nfs-service` command with the exact path in this row for the offline behavior to take effect.

The NFS client chooses one of these behaviors when mounting the NFS service. If the client’s **mount** command exactly matches a **Path** in any row, the client gets the **Behavior** in that row. Otherwise, the client gets the behavior in the row that matches the closest, with an ancestor **Path**, the same **Volume**, or the same **Namespace**.

You can use this output to determine the offline behavior that your NFS clients should expect from any given export.

**Samples**

```
bstnA> show nfs-service
```

shows all the front-end NFS services on the ARX. Sample output appears in [Figure 24.10](#).

```
bstnA> show nfs-service ac1.MEDARCH.ORG
```

shows the NFS service running at “ac1.MEDARCH.ORG.” See [Figure 24.11](#) for sample output.

```
bstnA> show nfs-service ac1.MEDARCH.ORG detailed
```

shows the NFS service running at “ac1.MEDARCH.ORG,” along with details about the offline-filer behavior. See [Figure 24.12](#) for sample output.

```
bstnA> show nfs-service acopiaFiler
```

shows the NFS service running at “acopiaFiler,” an NFS service where NLM is disabled. See [Figure 24.13](#) for sample output.

(\*) Return permission error for offline back-end shares.

## show nfs-service mounts

**Purpose** Use the `show nfs-service mounts` command to show all NFS mounts to one or more NFS services.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show nfs-service mounts {fqdn | all}`

*fqdn* (1-128 characters) specifies a particular NFS service (for example, “www.company.com”).

**all** shows all client connections to all NFS services.

**Guidelines** The output is a table of NFS mounts from client machines. Two rows of information describe each currently-active client mount:

Global Server identifies the global server that the client mounted. The global server’s name appears here as configured; depending on your external DNS configuration, it may not be an FQDN that is visible to clients. Use the `show global server` command for a full list of global servers, along with configuration details.

Mount Point is where the client connected. This is the volume path established in the `export (gbl-nfs)` command, possibly with an additional sub path.

Client IP Address identifies the client host.

[VIP] is the Virtual-IP address to which the client connected. This also appears in the output for `show global server`.

The total number of mount points appears at the bottom of the table.

**Note:** After a client un mounts, there may be a short time where the clients mount persists in the output.

Use the `show nfs-service` command to see NFS-service configuration and state.

**Samples** `bstnA> show nfs-service mounts all`

lists all mounts to all NFS services. For sample output, see [Figure 24.14](#).

`bstnA> show nfs-service mounts acopiaFiler`

lists all mounts to a particular NFS service. See [Figure 24.15](#) for sample output.

**Related Commands** `nfs`

`show nfs-service`

**Figure 24.14** Sample Output: `show nfs-service mounts all`

```
bstnA> show nfs-service mounts all
```

| Global Server<br>[VIP]         | Mount Point | Client IP Address |
|--------------------------------|-------------|-------------------|
| acopiaFiler<br>[192.168.25.12] | /vol/vol2   | 172.16.100.183    |

---

```
ac1.MEDARCH.ORG /acct 172.16.100.183
[192.168.25.15]
```

Total number of mount points displayed is 2.

**Figure 24.15** *Sample Output: show nfs-service mounts acopiaFiler*

```
bstnA> show nfs-service mounts acopiaFiler
```

```
Global Server Mount Point Client IP Address
[VIP]

acopiaFiler /vol/vol2 172.16.100.183
[192.168.25.12]
```

Total number of mount points displayed is 1.

## show nfs tcp

**Purpose** Use the `show nfs tcp` command to display the current timeout period for NFS/TCP connections to back-end shares, and the current client-side behavior in the event of this server-side timeout (disconnect or send an I/O error).

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show nfs tcp`

**Guidelines** Consider an NFS client that makes a request, where the ARX forwards the request to a back-end NFS server. If the server times out after 105 seconds, the switch disconnects the client by default. You can use [nfs tcp timeout](#) to change this reaction: instead of closing the client connection, NFS services can send an NFSERR\_IO (NFSv2) or NFS3ERR\_IO (NFSv3) back to the client application.

The output shows the current, system-wide setting for TCP timeouts:

Behavior is either “Close Connection” or “Return I/O Error.”

Inactivity is the timeout period.

**Sample** bstnA> `show nfs tcp`

```
Transaction Timeout
Behavior: Close Connection
Inactivity: 105 seconds
 shows that the timeout is set to its default values.
```

**Related Commands** [nfs tcp timeout](#)

---

## show nlm client

**Purpose** The NFS Lock Manager (NLM) manages file locks for NFS clients. Use the `show nlm client` command to display currently-held locks by one or all NFS-client machines.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show nlm client {all | hostname}`

`all` | *hostname* is a required choice:

`all` shows all NFS clients that hold any locks.

*hostname* (1-192 characters) identifies one client's host machine (for example, "myhost"). This shows all files locked by the given host.

**Guidelines** An NFS client can lock a file or a region within a file, so that other NLM-compliant users cannot access the region until the lock is released. The ARX's NLM server manages all the locks for all NFS front-end services and volumes.

The `show nlm client all` command presents a list of client hosts that currently hold locks, or held them over the last five minutes.

The `show nlm client hostname` command shows the SVID (the process ID of the lock holder), namespace, and file path for all files locked by one client. To see all clients that hold locks for one of these files, you can copy the namespace and file path from this output and paste it into the `show nlm file` command.

Use `show nlm statistics` to see statistics for all NLM activity. If a client machine is down, you can clear all of its locks with `clear nlm locks`.

To disable NLM for a given NFS service, disable NFS first (with `enable (gbl-cifs, gbl-nfs)`) and then use `no nlm enable`.

**Samples** `bstnA# show nlm client all`

```
NLM Clients

rh1 (192.168.25.19)
 finds that one client machine holds an NFS lock.
```

`bstnA# show nlm client rh1`

```
Locks held by rh1 (192.168.25.19)
```

```
SVID Namespace/Path

```

```
17098 wwmed /acct/rvcIndex.html
```

searches for locks held by clients at the "rh1" machine. It finds a single locked file in the wwmed~/acct volume.

**Related Commands** [show nlm file](#)  
[show nlm statistics](#)  
[clear nlm locks](#)  
**no** [nlm enable](#)

---

## show nlm file

**Purpose** The NFS Lock Manager (NLM) manages file locks for NFS clients. Use the `show nlm file` command to show which clients have locks on a given file.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show nlm file namespace file-path`

*namespace* (1-30 characters) is the file's namespace.

*file-path* (1-4096 characters) identifies the file to check.

**Guidelines** An NFS client can lock a file or a region within a file, so that other NLM-compliant users cannot access the region until the lock is released. The ARX's NLM server manages all the locks for all NFS front-end services and volumes.

This command shows all locks for the file at *file-path*. These are locks that are currently held or have been held in the last five minutes. The following information is shown for each lock:

Client is the host name of a lock-holding client.

SVID (System V Interface Definition) is process ID of the program that holds the lock.

Locked Region shows which bytes are locked in the file.

Type is either "Exclusive" or "Shared." An exclusive lock is held by a single client, blocking access from all others. A shared lock can be shared by multiple clients, allowing them all to read the region but not change it.

If any clients are waiting for a lock to free up, an additional table of "Waiters" appears before the "Locks" table. The "Waiters" table has the same columns as the "Locks" table.

To see all the locks held by a given client machine (or a list of all the client machines that have locks), use the `show nlm client` command. If a client is down, you can clear all of its locks with `clear nlm locks`. Use `show nlm statistics` to see statistics for all NLM activity.

To disable NLM for a given NFS service, disable NFS first (with `no enable (gbl-cifs, gbl-nfs)`) and then use `no nlm enable`.

This command fails if NLM is disabled for the all of the namespace's NFS services.

### Samples

```
bstnA# show nlm file wwmed /acct/rvcIndex.html
```

```
Locks on wwmed:/acct/rvcIndex.html
```

| Client | SVID  | Locked Region | Type      |
|--------|-------|---------------|-----------|
| rh1    | 17098 | 0-512         | Exclusive |

shows lock details for a file in the wwmed namespace, "/acct/rvcIndex.html."

```
bstnA# show nlm file EMC-NFS /NFS-EMC/lockfile
```

```
Locks on EMC-NFS:/NFS-EMC/lockfile
Client SVID Locked Region Type

dartagnon 4998 15-30 Shared
porthos 234 15-30 Shared
aramis 7898 15-30 Shared
athos 11375 0-15 Exclusive
athos 9372 4294967295-4294967310 Exclusive
dartagnon 765 15-30 Shared
porthos 4095 15-30 Shared
client89 19087 15-30 Shared
testrh8 7702 15-30 Shared
aramis 125 45-60 Exclusive
aramis 259375 281474976710655-281474976710670 Exclusive
```

```
Waiters on EMC-NFS:/NFS-EMC/lockfile
Client SVID Requested Region Type

dartagnon 4095 15-30 Exclusive
caller6 98223 15-30 Exclusive
```

shows lock details for a file in the EMC-NFS namespace, “/NFS-EMC/lockfile.”  
This file has several locks on it, and it has two clients waiting to put an exclusive lock on bytes 15-30.

**Related Commands** [show nlm client](#)  
[show nlm statistics](#)  
[clear nlm locks](#)  
[no nlm enable](#)

---

## show nlm statistics

**Purpose** The NFS Lock Manager (NLM) manages file locks for NFS front-end service clients. Use the `show nlm statistics` command to display NFS-lock statistics.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show nlm statistics`

**Guidelines** An NFS client can lock a file or a region within a file, so that other NLM-compliant users cannot access the region until the lock is released. The ARX's NLM server manages all the locks for all NFS front-end services and volumes.

This command shows a table of system-wide NLM statistics. All of these statistics are reset to 0 (zero) at boot-up time.

**Lock Requests** is the total number of locks requested.

**Locks Granted** is the number of locks that the NLM server granted to clients.

**Locks Denied** counts the number of client requests that were rejected.

**Locks Blocked** is the number of client requests where the lock is unavailable but client is willing to block until the lock is free.

**Unlock Requests** is the number of requests to unlock a file region (NLM\_UNLOCK requests).

**Test Requests** is the number of NLM\_TEST requests, which a client sends to check for the availability of a lock.

**Cancel Requests** is the number of NLM\_CANCEL requests, which a client sends cancel a blocked request.

**Current Locks Held** is the total locks that clients hold now, system-wide.

**Cached Clients** is the number of client machines with processes that hold (or recently held) locks. Lock-holding clients are cached for five minutes; this counts all the clients in that cache.

**Cached Processes** is the number of processes that have held locks over the past five minutes.

**Cached File Handles** is the number of NFS file handles that have been cached over the past five minutes. These identify files that have one or more locks on them.

**Unsupported Lock Calls** is the total number of DOS-file-sharing calls. The ARX does not support those NLM calls.

**Unimplemented Lock Calls** should always be zero; this indicates a malfunctioning client. If a client application is encountering NFS-locking errors (notably timeouts or hangs) then check this counter and look for NLM\_UNIMPLEMENTED messages in the syslog. Those syslog messages specify the unsupported NLM function that was called.

To see all the client machines that hold locks for a given file, use the [show nlm file](#) command. For a list locks held by a given client machine (or a list of all the client machines that have locks), use the [show nlm client](#) command. If a client is down, you can clear all of its locks with [clear nlm locks](#).

**Guidelines (Cont.)** To disable NLM for a given NFS service, disable NFS first (with `enable (gbl-cifs, gbl-nfs)`) and then use `no nlm enable`.

**Sample** See [Figure 24.16](#) for sample output.

**Related Commands** `show nlm file`  
`show nlm client`  
`clear nlm locks`  
`no nlm enable`

*Figure 24.16 Sample Output: show nlm statistics*

```
bstnA# show nlm statistics
```

```
NLM Statistics
```

```

Lock Requests 30
Locks Granted 15
Locks Denied 9
Locks Blocked 6
Unlock Requests 21
Test Requests 9
Cancel Requests 2

Current Locks Held 3

Cached Clients 1
Cached Processes 3
Cached File Handles 1

Unsupported Lock Calls 0
Unimplemented Lock Calls 0
```

---

## show virtual service

**Purpose** Use the `show virtual service` command to display the front-end services running on each virtual server.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show virtual service [hostname]`

*hostname* (optional; up to 128 characters) is the hostname for one ARX in the current redundant pair.

If no hostname is specified, this command lists the front-end services for both peers.

**Guidelines** This displays a table of front-end services, grouped by ARX.

**Switch** is the current ARX (or its redundant peer) where the virtual servers are running.

**Global Server** is the global server for which this virtual server is a host.

**Virtual IP Address** is the IP address where the front-end service is listening.

**Service** is the name of the front-end service:

- NFS or
- CIFS

**State** is the result of a health-check for the front-end service:

**Disabled** indicates that an administrator has disabled the front-end service, or that it was just enabled and is about to go into the **Starting** state. Use the [enable \(gbl-cifs, gbl-nfs\)](#) command to enable a disabled service.

**Starting** indicates that the NFS or CIFS service software is initializing or waiting for the exported volume(s) to become available. If **(No Running Volumes)** appears, too, the “Starting” state is frozen because of the service’s namespace(s); you can use [show cifs-service](#) or [show nfs-service](#) to find the namespace name(s), then use [show namespace](#) to examine each namespace and its volumes.

**Ready** indicates that the NFS or CIFS service is ready to serve file data to external clients.

**Stopping** indicates a transition from **Ready** to **Disabled**. The service stops because someone has disabled it (no [enable \(gbl-cifs, gbl-nfs\)](#)), or because someone has removed it (no [nfs](#) or no [cifs](#)).

**Failed** indicates that the service has failed its health check. Call F5 Support if this state appears.

**Suspended** means that an [nsck ... rebuild](#) is re-creating one of the service’s namespaces. When the rebuild finishes (or on reboot), the service goes back to the **Starting** state. Use [show nsck](#) to show the progress of all nsck jobs.

**Unreachable** indicates that the remote switch is unreachable over the RON, so the service state is unknown. Use [show ron](#) to examine the status of the RON.

**Guidelines (Cont.)**

These states should never appear, given that the CLI checks for these issues before it allows the virtual-server to be configured. Contact F5 if any of these results appear in the output:

- **VIP In Use** means that the VIP is the same as an internal IP address (such as a proxy IP) that is already in use.
- **VMAC Error** means that there are no virtual MAC (VMAC) addresses available to assign to the VIP (too many VIPs are already configured on this chassis).
- **VIP Error** is any other internal error.
- **Unknown** is an internal software error indicating that a virtual service has been configured but does not exist in the global service manager.
- **Invalid** is an internal software error indicating that the virtual service's internal numeric status value is invalid (values should vary from 1 to 10 only).

**Samples**

prtlnA> **show virtual service**

shows all virtual services on the “prtlnA” switch and its redundant peer. See [Figure 24.17](#) for sample output.

prtlnA> **show virtual service prtlnB**

focuses on “prtlnB,” the redundant peer.

**Related Commands**

[show global service](#)  
[show namespace](#)  
[enable \(gbl-cifs, gbl-nfs\)](#)  
[nsck ... rebuild](#)  
[show nsck](#)

*Figure 24.17 Sample Output: show virtual service*

---

# signatures

**Purpose** Use the `signatures` command to enable (or perhaps require) SMB signing between this CIFS front-end service and its clients. *SMB signing* is the process of placing a digital signature into each Server Message Block (SMB) exchanged between a CIFS server (this service) and any CIFS client. SMB signing prevents man-in-the-middle attacks at the cost of slower performance.

Use `no signatures` to refuse SMB signing from any CIFS clients. This prevents any new connections from clients that require SMB signing.

**Mode** `gbl-cifs`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `signatures [required]`  
`no signatures`

**required** (optional) obligates all CIFS clients to use SMB signing in their communication with this service. If any of the clients refuse to support SMB signing, they cannot connect to the service.

**Default(s)** `no signatures`

**Guidelines** Without SMB signing, the default for the CIFS service, clients that require SMB signing refuse to start a CIFS session.

If you use this command to declare SMB signatures `required`, the service only accepts connections from clients that support SMB signing.

The least-restrictive setting is to enable SMB signing without requiring it (using the simple `signatures` syntax). The CIFS service can then accept any client connection, whether it requires or refuses SMB signing. If a client requests or requires SMB signatures, the CIFS service complies.

To control the SMB-signing policy between one of the service's backing namespaces and its back-end filers, you can use the `cifs filer-signatures` command in `gbl-ns` mode. To find the backing namespace(s) for this CIFS service, use `show cifs-service fqdn`, where `fqdn` is the name of the CIFS service. To see the number of filers and/or clients who have used SMB signing, along with some success and failure statistics, use the `show fastpath cifs-signatures` command.

**Sample** `bstnA(gbl-cifs[ac1.medarch.org])# signatures`  
allows SMB signing for any client of the "ac1.medarch.org" service. If a client requests or requires SMB signing, the CIFS service will comply. For clients that disallow SMB signing, the CIFS service does not send or expect any signatures.

**Related Commands** `cifs`  
`enable (gbl-cifs, gbl-nfs)`  
`cifs filer-signatures`  
`show cifs-service`  
`show fastpath cifs-signatures`

## sync cifs delegation

**Purpose** You can use the `sync cifs delegation` command to immediately synchronize an ARX [cifs](#) service with its delegation settings in the Active Directory (AD). With the proper *delegation* settings, a CIFS client can authenticate at the ARX once and then access any of the back-end servers without re-authenticating. This delegation feature is set in the AD, outside the ARX. When someone changes the delegation settings at a domain controller (DC), the ARX software can take up to 10 minutes to synchronize with the changes. Use this command to make the synchronization immediate.

**Modes** `priv-exec`

**Security Role(s)** `network-technician, network-engineer, storage-engineer, or crypto-officer`

**Syntax** `sync cifs delegation {fqdn | all}`

*fqdn* (1-255 characters) is the FQDN for a [cifs](#) service whose delegation settings changed in the AD.

**all** synchronizes the delegation settings for all CIFS services on the ARX.

**Default(s)** None.

**Guidelines** *Delegation* enables multiple CIFS servers to delegate client authentications to a front-end CIFS service, so that clients can authenticate with the front-end service once and remain authenticated for connections with the back-end servers. We recommend trusting your ARX CIFS service for delegation, to enable this single-sign-on feature. It is generally recommended that you also *constrain* this delegation to the particular CIFS servers behind this service. You set this trust (at a DC) in the CIFS service's machine account, or you can set it with the [domain-join](#) command if you have sufficient privileges.

If the service uses constrained delegation, you can use the [probe delegate-to](#) command to confirm that all the servers behind a particular CIFS service are properly assigned to its “delegate” list. Clients can only access the storage on a back-end server that is on that list.

**Sample** `stkbngA# sync cifs delegation bgh.MEDARCH.ORG`

The `cifs` service 'bgh.MEDARCH.ORG' delegation type 'Constrained' is synchronized with AD.

`sync` synchronizes all deletion and constraint settings for the “bgh.MEDARCH.ORG” service.

**Related Commands** [domain-join](#)  
[show cifs-service](#)  
[probe delegate-to](#)

---

## wins-name-encoding

**Purpose** *Character encoding* is the mapping between binary numbers and written characters. Some character-encoding schemes use only a single byte for each character; these typically support alphabets without any Asian characters. Multi-byte encoding schemes encompass Asian character sets. Unicode (such as UTF-8) can also use more than one byte per character, and encompasses most character sets and languages. Use the `wins-name-encoding` command to set the CIFS service's character encoding for its NetBIOS names.

Use `no wins-name-encoding` to reset NetBIOS names back to the single-byte default.

**Modes** gbl-cifs

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `wins-name-encoding {utf-8 | shift-jis | cp932 | euc-jp  
| ksc5601 | iso-8859-1}`  
`no wins-name-encoding`

**utf-8** specifies UTF-8 (Unicode) character encoding.

**shift-jis** specifies Shift\_JIS (Japanese) character encoding.

**cp932** is Code Page 932, or Windows-31J (Japanese) character encoding. This is the Microsoft version of Shift\_JIS.

**euc-jp** specifies EUC-JP (Extended Unix Code - Japanese) character encoding.

**ksc5601** is KSC5601 (Korean) character encoding.

**iso-8859-1** is ISO 8859-1 (Latin1, single-byte) character encoding.

**Default(s)** ISO 8859-1 (Latin1)

**Guidelines** This command determines the character encoding used to register the [virtual server's](#) NetBIOS computer name (called the [wins-name](#)) with its [wins](#) server. This should be the encoding supported by the network's WINS server. This also determines the encoding for all of the virtual server's [wins-alias](#) names, as well as the server's group (or domain) name.

The [show global server fqdn](#) command shows the full WINS configuration for the *fqdn* service.

**Samples** `bstnA(gbl-cifs[ac1.medarch.org])# wins-name-encoding shift-jis`  
sets the character encoding to Shift\_JIS for the 'ac1.medarch.org' service. Whenever the [virtual server](#) registers its NetBIOS names with its [wins](#) server, it translates to Shift\_JIS for the registration.

`bstnA(gbl-cifs[ac1.medarch.org])# no wins-name-encoding`  
resets the character encoding for NetBIOS names to the default.

**Related Commands** [wins-name](#)  
[wins-alias](#)  
[show global server](#)

25

Schedules

---

## description (gbl-schedule)

**Purpose** You can use the optional **description** command to set a descriptive string for the current schedule. This appears in show commands.

Use the **no** form of the command to delete the description.

**Mode** gbl-schedule

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **description** *text*  
**no** **description**

*text* (1-256 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** **no** **description**

**Guidelines** The description appears in the output for [show schedule](#).

**Sample** bstnA(gbl-schedule[backupWindow])# **description "regular backup times"**  
specifies a description for the current schedule.

**Related Commands** [schedule](#)  
[show schedule](#)

## duration

**Purpose** Use the `duration` command to limit the amount of time that a rule can run each time the schedule fires. (A *schedule* is applied to a policy rule, to determine when and how frequently the rule should fire.)

Use `no duration` to allow the rule to run indefinitely every time.

**Mode** `gbl-schedule`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `duration HH:MM[:00]`  
`no duration`

*HH:MM[:00]* is the duration allowed for any rule on this schedule (for example, `00:30:00` for 30 minutes). The only accepted value for seconds is `00` (zero).

**Default(s)** `no duration` - no limit on the rule's duration

**Guidelines** Use this command to impose a limit on all rules that use the current schedule. If (during any run) the rule exceeds this time limit, the rule stops processing. For example, if you set a 2-minute duration for a [place-rule](#)'s schedule and one run of the rule exceeds the limit, that run stops. This stops any volume scan in progress, cancels all migrations, and causes the policy engine to start recording files or directories that clients change (if they now match the placement rule's fileset, they are queued for migration when the schedule next fires). New files and directories, which are directed to a share before they are created, are unaffected by an expired duration.

**Samples** `bstnA(gbl-schedule[fridays])# duration 00:15`  
sets a 15-minute duration for the "fridays" schedule.

`bstnA(gbl-schedule[daily])# no duration`  
removes any time limit for rules that run on the "daily" schedule.

**Related Commands** [schedule](#)

---

## every

**Purpose** Use the `every` command to determine the current schedule's frequency.

**Mode** `gbl-schedule`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `every count {minutes | hours | days | weeks | months | quarters | years}`  
`every {sunday | monday | tuesday | ... saturday}+`  
`every first {sunday | monday | tuesday | ... saturday}`  
`every last {sunday | monday | tuesday | ... saturday}`  
`every day-list day-of-month[,day-of-month]+`  
`every hour-list hour:minute[,hour:minute]+`

**count** {minutes | ... | years} creates a simple schedule with a single time period between each time that the schedule fires. For example, **every 2 weeks** or **every 5 hours**.

**count** (1-4294967295) is the number of minutes, hours, days, etc. between scheduled events.

**minutes | ... | years** is a required choice.

**sunday | ... | saturday** creates a weekly schedule that fires on the given day or days of the week.

**first sunday | ... | saturday** makes a monthly schedule that fires on the first given day of the month.

**last sunday | ... | saturday** creates a monthly schedule that fires on the last given day of the month.

**day-list** results in a schedule that runs on one or more days of the month. For example, **day-list 10,20** creates a schedule that fires on the 10th and the 20th of each month. If you enter 31, the policy engine fires on the last day of the month, whether or not the month has 31 days.

**hour-list** makes a schedule that runs on one or more times of the day. Use a 24-hour clock to specify the hours. For example, **hour-list 04:00,12:00,23:00** fires three times per day: it fires at 4 AM, noon, and 11 PM.

**Default(s)** `every 1 weeks`

**Guidelines** To set a start time and/or date for the schedule, use the `start` command. If you choose an `every` command that does not include a time (such as `every first tuesday`), the start time determines the time of day that the schedule fires.

**Samples** `bstnA(gbl-schedule[hourly])# every 1 hours`  
sets an hourly interval.

`prtIndA(gbl-schedule[payday])# every tuesday thursday`  
makes a weekly schedule that fires every Tuesday and Thursday.

`prtIndA(gbl-schedule[quarterly])# every 3 months`  
sets a quarterly interval.

`stkgbrgA(gbl-schedule[threeDaily])# every hour-list 03:00,13:00,22:00`  
sets a schedule that fires three times a day: at 3 AM, 1 PM, and 10 PM.

`bstnA(gbl-schedule[monthly_tues])# every first tuesday`  
makes a monthly schedule that fires on the first Tuesday of each month.

**Related Commands** [schedule](#)  
[start](#)

---

# schedule

**Purpose** Some policy rules, such as the shadow-copy rule, operate on a schedule. Use the `schedule` command to create a new schedule.

Use `no schedule` to delete a schedule.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `schedule name`  
`no schedule name`

*name* (1-64 characters) is the name you choose for the schedule.

**Default(s)** None.

**Guidelines** Some rules operate in discrete sessions instead of continuously, so they use a schedule to determine when to operate. For example, a shadow-copy rule copies its fileset from the source volume to the shadow volume; each shadow-copy session occurs on a schedule.

This command places you in gbl-schedule mode, where you define the period for the schedule (every 3 hours, every day, every 2 weeks, or some other period) with the `every` command. You can also define an optional `start` time and/or date; the default start time is the moment that you create the schedule. If you want to impose a time limit on rules each time they run, you can use the `duration` command. The optional `description (gbl-schedule)` command assigns a descriptive string to the schedule. To set an expiration date for the schedule, use the `stop` command.

Use the `schedule (gbl-ns-vol-plc)` command to assign a schedule to a file-placement rule. Use the `schedule (gbl-ns-vol-shdwcp)` command to assign a schedule to a shadow-copy rule. The `schedule (gbl-ns-vol-...snap)` command assigns a schedule to a snapshot rule. To assign a schedule to auto-diagnostics collection, which monitors usage trends on the chassis, you can use the `schedule (gbl-auto-diag)` command.

**Samples** `bstnA(gbl)# schedule hourly`  
`bstnA(gbl-schedule[hourly])#`  
 creates a schedule named "hourly."

`prt1ndA(gbl)# no schedule every_2_months`  
 deletes a schedule.

**Related Commands** `every`  
`start`  
`stop`  
`duration`  
`description (gbl-schedule)`  
`schedule (gbl-ns-vol-plc)`  
`schedule (gbl-ns-vol-shdwcp)`  
`schedule (gbl-ns-vol-...snap)`  
`schedule (gbl-auto-diag)`

## show schedule

**Purpose** Use the `show schedule` command to view all schedules.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator

**Syntax** `show schedule [schedule-name]`

*schedule-name* (optional, 1-64 characters) focuses the command on a single schedule. If a name is not specified, all schedule names are displayed.

**Guidelines** The following fields appear for each schedule:

**Schedule** is the schedule's configured name, set by the `schedule` command.

**Description** only appears if set by the `gbl-schedule description (gbl-schedule)` command.

**Start Time** can be reset by the `gbl-schedule start` command. This is the date and time of day used for all time-based calculations: for example, if a schedule runs every Wednesday, this determines the time of day on Wednesdays when the schedule fires.

**Stop Time** only appears if set by the `gbl-schedule stop` command. This is the expiration time for the schedule, after which the schedule never fires.

**Interval** is set by the `gbl-schedule every` command. This is the time between scheduled runs.

**Duration** appears only if set by the `gbl-schedule duration` command. This is the amount of time allotted for migrations or replications before a scheduled rule goes into a *paused* state (similar to the one invoked by the `policy pause (gbl-ns-vol)` command.) A 0 (zero) means that there is no limit on the duration: each time a rule runs on this schedule, it can run indefinitely.

**Status** is "Paused" (the schedule is between run times), "Running," or "Waiting for start time" (the schedule has never been invoked).

**Previous** is a sub-table showing the **Run time** (when the run started) and **End time** of the most-recent run.

**Current** appears if the rule is currently running. This has the same fields as the **Previous** table, **Run time** and **End time**.

**Next** shows when the schedule's next run will begin.

**Sample** `bstnA# show schedule`  
shows all schedules. See [Figure 25.1 on page 25-8](#) for sample output.

**Related Commands** [show policy](#)  
[show policy filesets](#)

 End Time: N/A
```

## start

**Purpose** Use the **start** command to set a start time for the current schedule. A *schedule* is applied to a policy rule, to determine when and how frequently the rule should fire. Use **no start** to eliminate the fixed start time from the schedule; this resets the start time to now.

**Mode** gbl-schedule

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **start** [*mm/dd/yyyy:HH:MM[:00]*]  
**no start**

*mm/dd/yyyy:HH:MM[:00]* (optional) is the date and time to start the schedule (for example, **05/06/2005:06:00**). The only accepted value for seconds is 00 (zero). If you omit this, you reset the start time to now and start the schedule immediately.

**Default(s)** now

**Guidelines** This command sets a starting point for all scheduling calculations. For example, if you have a daily schedule, this determines the time of day. If you have a weekly schedule, this also determines the day of the week.

If you set a start date/time in the future, the schedule waits until that time.

A **no start** resets the date/time to now, but does not fire the schedule.

**Samples** `bstnA(gbl-schedule[daily])# start 11/12/2004:23:00`  
sets a start date of November 12, 2004, at 11PM.

`prtIndA(gbl-schedule[weekly])# start`  
starts the weekly schedule now.

`prtIndA(gbl-schedule[hourly])# no start`  
resets the hourly schedule's start time to now, but does not invoke any rules.

**Related Commands** [schedule](#)

---

## stop

**Purpose** The `stop` command establishes an optional end date for the current schedule. A *schedule* is applied to a policy rule, to determine when and how frequently the rule should run. The schedule stops functioning after this date and time; any rule on the schedule stops all future runs.

Use `no stop` to eliminate any end date for the schedule.

**Mode** gbl-schedule

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `stop [mm/dd/yyyy:HH:MM[:00]]`  
`no stop`

*mm/dd/yyyy:HH:MM[:00]* (optional) is the date and time to stop the schedule (for example, **10/24/2022:18:00**). The only accepted value for seconds is 00 (zero). If you omit this, you stop the schedule now, so that rules using the schedule will never run in the future.

**Default(s)** None

**Guidelines** This command sets an expiration date on the entire schedule. To limit the amount of time allotted to each scheduled run, use the [duration](#) command. You can use the [start](#) command to determine the first day and time that the schedule runs.

If you set a stop date/time in the past, the schedule never runs.

**Sample** `bstnA(gbl-schedule[daily4am])# stop 01/07/2011:04:00`  
sets a stop date of January 7, 2011, at 4 AM. The schedule will never fire again after that date and time.

**Related Commands** [schedule](#)

[duration](#)

# 26

---

---

## Filesets

---

---

This chapter contains an alphabetical list of commands for configuring a *fileset*, a group of files in a managed volume. You can use the commands in this chapter to create filesets based on file name, age, directory path, and various other criteria.

---

## age-fileset

**Purpose** Use the `age-fileset` command to create a simplified age-based fileset for the current volume.

**Mode** `gbl-ns-vol`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `age-fileset name`  
`no age-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** None

**Guidelines** This command creates a fileset that is only usable in the current volume. To create a global fileset, usable from any namespace or volume, use [policy-age-fileset](#) in `gbl` mode.

The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-ns-vol-fs-age` mode, where you use several commands to define the fileset. You must use the [select-files \(...-fs-age\)](#) command to choose files older than (and/or newer than) 1 hour, 2 days, 20 minutes, or some other interval; this establishes the age. To determine whether the age is based on the last time the files were accessed or the last time they were modified, use the [last](#) command.

An age fileset selects its files each time a rule uses it. The rule's assigned schedule controls when it uses the fileset; each time the rule's schedule fires, it assesses every file's age from that moment. That is, "one hour old" or "one day old" is measured at the moment that the rule runs. The [schedule \(gbl-ns-vol-plc\)](#) command assigns a schedule to a file-placement rule, and the [schedule \(gbl-ns-vol-shdwcp\)](#) command assigns one to a shadow-copy rule.

**Sample** `bstnA(gbl-ns-vol[medarcv~/rcrds])# age-fileset 24hrs`  
 This will create a new policy object.

```
Create object '24hrs'? [yes/no] yes
bstnA(gbl-ns-vol-fs-age[medarcv~/rcrds~24hrs])# ...
 defines the '24hrs' fileset.
```

**Related Commands** [policy-age-fileset](#)  
[select-files \(...-fs-age\)](#)  
[last](#)  
[schedule \(gbl-ns-vol-plc\)](#)  
[schedule \(gbl-ns-vol-shdwcp\)](#)

## every (...-fs-age)

**Purpose** \*\* Deprecated \*\*

Use the **every** command to determine the how frequently the current age fileset re-selects its files.

Use **no every** to select files only when a policy rule (such as a [place-rule](#) or a [shadow-copy-rule](#)) invokes the fileset.

**Modes** gbl-fs-age  
gbl-ns-vol-fs-age

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **every** *count* {minutes|hours|days|weeks|months|quarters|years}  
**every** {sunday|monday|tuesday| . . . |saturday}  
**no every**

*count* (1-2,147,483,647) is the number of minutes, hours, days, etc. between file selections. For example, **every 2 minutes** or **every 5 minutes**.

**minutes| . . . years** is a required choice.

**sunday| . . . saturday** causes the fileset select its files weekly, on the given day of the week.

**Default(s)** None; select files whenever the fileset is used by a policy rule (such as a [place-rule](#) or a [shadow-copy-rule](#)).

**Guidelines** This command is deprecated in favor of controlling age selection from the rule's schedule. Consider instead using the [schedule \(gbl-ns-vol-plc\)](#) command (for a file-placement rule) or the [schedule \(gbl-ns-vol-shdwcp\)](#) command (for a shadow-copy rule). These assign a schedule to the rule. Every time the assigned schedule fires, the rule reassesses the age-based fileset from the scheduled time. For example, if the schedule fires on 11/12, a month-old file is one that was modified before 10/12; if the schedule fires again in 11/13, a month-old file is one that was modified before 10/13. This command creates a different schedule for file assessment. To continue the example, all "month-old files" may remain the ones modified before 10/12 for a long time, as determined by the algorithm described below.

In most-all cases, it is more intuitive to let the rule's schedule determine all file selections.

---

**Guidelines:** This command determines how frequently the policy engine selects files for the current age fileset. At each interval, the policy engine re-selects its files based on the current time. For example, consider a fileset with files “older than 1 week” that selects its files **every 1 day**:

1. Saturday: select all files that were modified before last Saturday.
2. Sunday: select all files that were modified before last Sunday.
3. Monday: select files modified before last Monday.
4. ...

If the same fileset was evaluated **every 2 days**, the progression would look like this:

1. Saturday: select all files that were modified before last Saturday.
2. (Sunday: do nothing; keep the selection of all files that were modified before last Saturday.)
3. Monday: select files modified before last Monday.
4. ...

The time of day when the files are selected is the start time for the fileset. This is either the time of day when the fileset is invoked by a rule or the fixed time/date set with the [start](#) command.

The **no every** command resets this command and **start** at the same time: it makes the fileset select its files whenever a rule invokes the fileset.

**Samples** `bstnA(gbl-fs-age[hourOld])# every 1 hours`  
sets an hourly selection interval.

`bstnA(gbl-fs-age[sixMonths])# no every`  
reverts to the default; select files whenever the rule runs (as controlled by its schedule). This is considered a best practice.

**Related Commands** [age-fileset](#)  
[start](#)

## filename-fileset

**Purpose** Use the `filename-fileset` command to create a name-based fileset for the current namespace volume.

Use the `no` form of the command to delete a name-based fileset.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `filename-fileset name`  
`no filename-fileset name`

*name* (1-1024 characters) is a required name that you assign to the fileset.

**Default(s)** `None`

**Guidelines** This command creates a fileset that is only usable in the current volume. To create a global fileset, usable from any namespace or volume, use [policy-filename-fileset](#) in `gbl` mode.

The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-ns-vol-fs-name` mode where you can define the fileset by choosing file names (with [name](#)), one or more directory [paths](#) within the volume, and/or an option to match files recursively ([recurse](#)). By default, a new file-name fileset matches all files in the volume's root directory, but not below it.

**Samples** `bstnA(gbl-ns-vol[ns~/])# filename-fileset logs`  
This will create a new policy object.

```
Create object 'logs'? [yes/no] yes
creates a name-based fileset, "logs."
```

```
bstnA(gbl-ns-vol[ns~/])# no filename-fileset logs
deletes a name-based fileset, "logs."
```

**Related Commands** [policy-filename-fileset](#)  
[name](#)  
[path](#)  
[recurse](#)

---

# filesize-fileset

**Purpose** Use the `filesize-fileset` command to create a size-based fileset for the current volume.

**Mode** `gbl-ns-vol`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `filesize-fileset name`  
`no filesize-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** None

**Guidelines** This command creates a fileset that is only usable in the current volume. To create a global fileset, usable from any namespace or volume, use [policy-filesize-fileset](#) in `gbl` mode.

The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-ns-vol-fs-filesize` mode, where you use the [select-files \(...-fs-filesize\)](#) command to choose the size range for the fileset's files.

**Sample** `bstnA(gbl-ns-vol[medarcv~/rcrds])# filesize-fileset big`  
This will create a new policy object.

```
Create object 'big'? [yes/no] yes
bstnA(gbl-ns-vol-fs-filesize[medarcv~/rcrds~big])# ...
 defines the 'big' fileset.
```

**Related Commands** [policy-filesize-fileset](#)  
[select-files \(...-fs-filesize\)](#)

## from fileset (gbl-...-fs-...)

**Purpose** Use the `from fileset` command to include a component fileset into the current union or intersection fileset.

Use the `no from` command to remove a component fileset from the current fileset.

**Modes** gbl-fs-isect  
gbl-ns-vol-fs-isect  
gbl-fs-union  
gbl-ns-vol-fs-union

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `[no] from fileset fileset-name`  
`no from [all]`

*fileset-name* (1-1024 characters) is the name of an existing source fileset.

**all** (optional) removes all source filesets from the union or intersection fileset.

**Default(s)** None

**Guidelines** This command pulls other filesets into the current, compound fileset.

The `no from all` command removes all source filesets at once.

**Samples** `bstnA(gbl-fs-union[bulky])# from fileset fm_pdf`  
`bstnA(gbl-fs-union[bulky])# from fileset veryLarge`  
adds two filesets to a union fileset named “bulky.” (The “bulky” fileset is defined in gbl-fs-union mode, so you can use it in any volume.)

`prtIhdA(gbl-ns-vol-fs-union[nemed~/acctShdw~test])# no from all`  
removes all source filesets from a union fileset named “test.” (The “test” fileset is defined within the /acctShdw volume, so it is limited to rules in that volume.)

**Related Commands** [policy-intersection-fileset](#)  
[intersection-fileset](#)  
[policy-union-fileset](#)  
[union-fileset](#)

---

# intersection-fileset

**Purpose** Use the `intersection-fileset` command to create an intersection fileset in the current namespace volume. An intersection fileset contains all files that are common to all of its source filesets.

Use the `no` form of the command to delete the intersection fileset.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `intersection-fileset name`  
`no intersection-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** `None`

**Guidelines** This command creates a fileset that is only usable in the current volume. To create a global-intersection fileset, usable from any namespace or volume, use [policy-intersection-fileset](#) in `gbl` mode.

The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.)

An intersection fileset contains files that are common to two or more source filesets. This command places you in `gbl-ns-vol-fs-isect` mode; from there, use the [from fileset \(gbl-...-fs-...\)](#) command to identify each source fileset.

**Samples** `bstnA(gbl-ns-vol[ns~/vol])# intersection-fileset xmlViaFtp`  
 This will create a new policy object.

```
Create object 'xmlViaFtp'? [yes/no] yes
bstnA(gbl-ns-vol-fs-isect[ns~/vol~xmlViaFtp])#
 creates an intersection fileset.
```

```
bstnA(gbl-ns-vol[archives~/etc])# no intersection-fileset isectTst
 removes an intersection fileset.
```

**Related Commands** [policy-intersection-fileset](#)  
[from fileset \(gbl-...-fs-...\)](#)

# last

**Purpose** Use the `last` command to set the type of timestamp to use for age-based grouping: last-accessed time or last-modified time.

**Modes** `gbl-fs-age`  
`gbl-ns-vol-fs-age`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `last {accessed | modified}`

`accessed` | `modified` is a required choice:

`accessed` is the last-accessed (read) time.

`modified` is the last-modified (written) time.

**Default(s)** `last modified`

**Guidelines** The last-accessed time is the time that the file was last read. The last-modified time is the time that the file was last written.

**Sample** `bstnA(gbl-ns-vol-fs-age[ns~/vol~weeklyHttpLogs])# last accessed`  
sets last-accessed times.

**Related Commands** [age-fileset](#)

---

## name

**Purpose** Use the `name` command to select a file name or names for the current name-based fileset.

Use `no name` to erase the selection, thereby matching any file name.

**Modes** `gbl-fs-name`  
`gbl-ns-vol-fs-name`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `name exact [not] file-name [ignore-case]`  
`name match [not] wild-card-string [ignore-case]`  
`name regexp [not] "regular-expression" [ignore-case]`  
`no name`

**not** (optional) negates the match; this causes the fileset to include all files in the fileset's `path` *except* any files that match.

**exact file-name** (1-1024 characters) is an exact file name to match.

**ignore-case** (optional) tells the rule to match files without paying attention to case (for example, `name exact index.html ignore-case` matches "index.html" and "Index.HTML").

**match wild-card-string** (1-1024 characters) uses a wild-card pattern to match multiple file names. See the *Guidelines* below for your wildcard options.

**regexp "regular-expression"** (1-1024 characters) uses a more-complex match pattern, based on the ICU standard for regular expressions. This also requires the quotation marks. See the *Guidelines* below for regular-expression syntax.

**Default(s)** match every file in the fileset's `path`

**Guidelines** You can use the `path` command (for example, `path exact /var/log`) to select a particular directory. You can optionally use the `recurse` to descend from a `path` into its subdirectories.

The `no` form of this command makes the fileset match all files in the fileset's `path(s)`.

**Guidelines:  
 Wildcard-String  
 Options**

The *wild-card-string* uses the following Unix-like shell conventions:

\* is any string of 0 (zero) or more characters, including an empty string.

? is any single character, or no character.

[...] matches any one of the enclosed characters. For example, [xyz] matches x, y, or z.

[a-z] matches any character in the sorted range, a through z.

[^...] or [!...] matches any character that is *not* enclosed. For example, [!xyz] matches any character *except* x, y, or z.

**Guidelines: Regular Expressions**

The *regular-expression* syntax follows IBM's ICU conventions. You can use this expression to be extremely specific about your match criteria. At a high level, these are the conventions for ICU regular expressions:

`.*` matches any string, including the null string.

`.?` matches any single character, or no character.

`[...]` matches any one of the enclosed characters.

`[a-z]` matches any character in the sorted range, a through z.

`[^...]` matches any character that is *not* enclosed.

`\d` matches any digit, 1-9.

`\s` matches any white-space character.

`\` matches the next character, even if that character is a special character (for example, `\?` is a literal “?”; it is not interpreted).

`^...` and `...$` match the beginnings and ends of lines, respectively.

`expression1 | expression2` matches both expressions.

For more details, refer to [Regular Expression Syntax](#), on page 13-11 of the [ARX® CLI Storage-Management Guide](#). Also, you can search the World-Wide Web for instructions on ICU regular expressions.

**Samples**

`bstnA(gbl-fs-name[xmlFiles])# name match *.xml*`

matches all files with “.xml” in their names (such as “addresses.xml” and “testData.xmllint.output”).

`bstnA(gbl-fs-name[xmlFiles])# name regexp “.xml$”`

matches all files whose names end with “.xml” (that is, “addresses.xml” matches but “testData.xmllint.output” does not).

`bstnA(gbl-fs-name[noHTML])# name match not .htm?`

matches all files except those with “.htm” or “.htm $x$ ” (where  $x$  could be any single character) in their names.

`bstnA(gbl-fs-name[httpLogs])# no name`

matches all files in this fileset's [path](#).

**Related Commands**

[policy-filename-fileset](#)  
[filename-fileset](#)  
[path](#)  
[recurse](#)

---

# offline

**Purpose** Some back-end CIFS servers use Hierarchical Storage Management (HSM) systems to archive file data on a remote server. A small portion of the file remains on the CIFS server while the bulk of the file is stored remotely. The small, local file has an *offline* attribute set. Whenever a client (such as the ARX) accesses the file, the HSM restores the full file contents to the CIFS server.

A large-scale file migration could restore a large number of offline files all at once, possibly enough to run out of disk space on the back-end CIFS server. You can use the `offline` command to choose files based on the setting for their offline attribute. You can then exclude files with a raised offline attribute from a [place-rule](#) migration.

**Mode** gbl-fs-cifs-attr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `offline {set | not-set | ignore}`  
`no offline`

`set | not-set | ignore` is a required choice:

`set` indicates that files in this fileset are all offline. We do not generally recommend migrating files (see [place-rule](#)) with the offline attribute set. The file's behavior is dependent on the back-end file server and the HSM; they may or may not restore the full file first. Additionally, assuming that the migration causes the file to be restored first, the change in the file may trigger a higher-priority rule and cancel the migration.

`not-set` matches only files that are online.

`ignore` matches all files, no matter how the offline attribute is set.

`no offline` is equivalent to `offline ignore`.

**Default(s)** `no offline`

**Guidelines** The offline attribute indicates whether or not the file has the bulk of its data stored on a remote server. Use this command in a [policy-cifs-attributes-fileset](#) to select all files in a volume based on this attribute setting.

**Sample** `bstnA(gbl-fs-cifs-attr[online])# offline not-set`  
selects files whose offline attribute is lowered. These files are at full size on the back-end CIFS server.

**Related Commands** [policy-cifs-attributes-fileset](#)

## path

**Purpose** Use the `path` command to choose one or more directories for the current named-based fileset.

This allows you to narrow the fileset scope to one or more directories inside the namespace volume. Only matching files from this directory are included in the fileset.

Use `no path` to revert to the default path.

**Modes** `gbl-fs-name`  
`gbl-ns-vol-fs-name`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `path exact [not] dir-path [ignore-case]`  
  
`path match [not] wild-card-string [ignore-case]`  
  
`path regexp [not] "regular-expression" [ignore-case]`  
`no path`

**not** (optional) negates the match; this causes the fileset to search all paths in the volume *except* any paths that match.

***dir-path*** (1-1024 characters) is an exact path to match.

**ignore-case** (optional) tells the rule to match paths without paying attention to case (for example, `path exact /src ignore-case` matches `/src` and `/SRC`).

**match *wild-card-string*** (1-1024 characters) uses wild cards to match multiple paths. See the *Guidelines* below for your wildcard options.

**regexp "*regular-expression*"** (1-1024 characters) uses a more-complex match pattern, based on the ICU standard for regular expressions. This also requires the quotation marks. See the *Guidelines* below for regular-expression syntax.

**Default(s)** `/` (but no subdirectories) in the volume that uses this fileset.

**Guidelines** This command specifies one or more directories for a name-based fileset. Only files in these directories are eligible for inclusion in this fileset. Use the `name` command to choose the files themselves.

By default, this does not recurse; use the `recurse` command to include all matching subdirectories in the fileset, too. Note that the `match` and `regexp` options often create a recursive effect: for example, the `path match "/var/*"` command matches `/var/`, `/var/log/`, `/var/log/httpd/`, `/var/www/`, and any other subdirectory under `/var/`.

The `path exact dir-path` syntax identifies a single directory, and does not require a full volume scan. All other options (including **not** and **ignore-case**) may match multiple directories, so they require more time for a full scan.

**Guidelines:  
Wildcard-String  
Options**

The *wild-card-string* uses the following Unix-like shell conventions:

- \* is any string of 0 (zero) or more characters, including an empty string.
- ? is any single character.

**◆ Note**

*The \* and the ? match any character, including a "/" (the Unix delimiter for directories). Therefore, path match "/home\*/bin" matches "/home/juser/bin/" as well as "/home/jrandom/misc/bin/."*

[...] matches any one of the enclosed characters. For example, [xyz] matches x, y, or z.

[a-z] matches any character in the sorted range, a through z.

[^...] or [!...] matches any character that is *not* enclosed. For example, [!xyz] matches any character *except* x, y, or z.

**Guidelines: Regular  
Expressions**

The *regular-expression* syntax follows IBM's ICU conventions. You can use this expression to be extremely specific about your match criteria. At a high level, these are the conventions for ICU regular expressions:

.\* matches any string, including the null string.

.? matches any single character.

[...] matches any one of the enclosed characters.

[a-z] matches any character in the sorted range, a through z.

[^...] matches any character that is *not* enclosed.

\d matches any digit, 1-9.

\s matches any white-space character.

\ matches the next character, even if that character is a special character (for example, \? is a literal "?"; it is not interpreted).

^... and ...\$ match the beginnings and ends of lines, respectively.

*expression1 | expression2* matches both expressions.

For more details, refer to [Regular Expression Syntax](#), on page 13-11 of the [ARX® CLI Storage-Management Guide](#). Also, you can search the World-Wide Web for instructions on ICU regular expressions.

**Samples** `bstnA(gbl-ns-vol-fs-name[ns~/vol~logs])# path exact /var/http/log`  
sets the current fileset to contain files in /var/http/log.

`bstnA(gbl-fs-name[httpLogs])# path match /log ignore-case`  
includes any directories with “/log” in their paths, in any case, such as “/var/log”  
and “/home/juser/log,” or “/LOG.”

`bstnA(gbl-fs-name[noHid])# path regexp not “/\.[^\.]”`  
includes all directories unless their names start with “.” followed by some other  
character.

`bstnA(gbl-fs-name[xslfiles])# no path`  
sets the current fileset to contain files in the volume’s root, /.

**Related Commands** [policy-filename-fileset](#)  
[filename-fileset](#)  
[name](#)  
[recurse](#)

---

# policy-age-fileset

**Purpose** Use the `policy-age-fileset` command to create an age-based fileset for any volume.

**Mode** `gbl`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `policy-age-fileset name`  
`no policy-age-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** `None`

**Guidelines** The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-fs-age` mode, where you use several commands to define the fileset. You must use the [select-files \(...-fs-age\)](#) command to choose files older than (and/or newer than) 1 hour, 2 days, 20 minutes, or some other interval; this establishes the age. To determine whether the age is based on the last time the files were accessed or the last time they were modified, use the [last](#) command.

An age fileset selects its files each time a rule uses it; you can alter this by setting a regular schedule for file selection. The optional [every \(...-fs-age\)](#) command sets the frequency of these file selections; by the time a rule invokes the fileset, its files are already selected based on an earlier, scheduled time. You can use the [start](#) command to set a start date (and time) for this fixed schedule (for example, start the “every 10 minutes” schedule at noon on January 1st). These commands are deprecated, however, in favor of letting the rule’s schedule determine file-selection schedule.

This type of fileset is available to all namespaces and volumes. To create a similar fileset in a single volume, use [age-fileset](#) in `gbl-ns-vol` mode.

You cannot remove this global fileset if any volume or rule uses it.

**Samples** `bstnA(gbl)# policy-age-fileset weekOld`  
This will create a new policy object.

```
Create object 'weekOld'? [yes/no] yes
bstnA(gbl-fs-age[weekOld])# ...
 defines the 'weekOld' fileset. Any volume can use this age-based fileset.
```

```
bstnA(gbl)# no policy-age-fileset lastMonth
bstnA(gbl)# ...
 removes an age fileset, 'lastMonth.'
```

**Related Commands** [select-files \(...-fs-age\)](#)  
[last](#)  
[every \(...-fs-age\)](#)  
[start](#)  
[age-fileset](#)

## policy-cifs-attributes-fileset

**Purpose** Use the `policy-cifs-attributes-fileset` command to create a fileset based on CIFS attributes. Some CIFS attributes can be important for file migrations, such as the *offline* attribute. The offline attribute indicates that the file's full content is on a remote server, and would need to be fully restored before accessing it for migration. You can use this fileset to select files with particular CIFS attributes and carefully manage their migration.

**Mode** gbl

**Security Level** storage-engineer or crypto-officer

**Syntax** `policy-cifs-attributes-fileset name`  
`no policy-cifs-attributes-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-fs-cifs-attr` mode, where you use the `offline` command to choose files based on the setting for their CIFS *offline* attribute.

If a file has its CIFS offline bit set, the file has been reduced to a stub with most of its contents archived on another server. The CIFS filer first recovers the full contents of the file if the ARX migrates it. This can fill the CIFS filer's disk if it occurs for too many files at once. You can use this fileset to identify all files with this CIFS attribute and migrate them (or avoid migrating them) accordingly.

The offline setting is the only supported CIFS attribute in a CIFS-attribute fileset.

This type of fileset is available to all namespaces and volumes that support CIFS. This does not apply to an NFS-only namespace, and there is no analogous command in `gbl-ns-vol` mode.

You can combine this fileset with others using [policy-union-fileset](#) and [policy-intersection-fileset](#). For example, to select all files with the offline attribute unset and in a particular directory, you can

- define the particular directory in a [policy-filename-fileset](#),
- define a set of online files with this command (`policy cifs-attributes-fileset`) and `offline not-set`,
- join the two filesets in an [policy-intersection-fileset](#), and
- use the intersection fileset in the `from (gbl-ns-vol-plc)` command of a [place-rule](#).

You cannot remove this global fileset if any rule uses it.

**Guidelines: Place Rules with this Fileset May Need Schedules**

The policy engine only finds the offline-file attribute during a scheduled scan of the volume's back-end filers. There are no inline (client-driven) events that indicate that the attribute changed. Therefore, any [place-rule](#) that uses this fileset only assesses the attribute once unless it has a [schedule \(gbl-ns-vol-plc\)](#).

**Samples** `bstnA(gbl)# policy-cifs-attributes-fileset online`

This will create a new policy object.

Create object 'online'? [yes/no] **yes**

`bstnA(gbl-fs-cifs-attr[online])# ...`

defines the 'online' fileset. Any volume can use this attribute-based fileset.

`bstnA(gbl)# no policy-filesize-fileset offline_not_set`

`bstnA(gbl)# ...`

removes an attribute-based fileset, 'offline\_not\_set.'

**Related Commands** [offline](#)

## policy-filename-fileset

**Purpose** Use the `policy-filename-fileset` command to create a name-based fileset for any volume.

Use the `no` form of the command to delete a name-based fileset.

**Mode** `gbl`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `policy-filename-fileset name`  
`no policy-filename-fileset name`

*name* (1-1024 characters) is a required name that you assign to the fileset.

**Default(s)** `None`

**Guidelines** The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This command places you in `gbl-fs-name` mode where you can define the fileset by choosing file names (with [name](#)), one or more directory [paths](#) within the volume, and/or an option to descend into matching directories recursively ([recurse](#)). By default, a new file-name fileset matches all files in the volume's root directory, but not below it.

This type of fileset is available to all namespaces and volumes. To create a similar fileset in a single volume, use [filename-fileset](#) in `gbl-ns-vol` mode.

You cannot remove this global fileset if any volume or rule uses it.

**Samples** `bstnA(gbl)# policy-filename-fileset logs`  
This will create a new policy object.

```
Create object 'logs'? [yes/no] yes
 creates a name-based fileset, "logs."
```

```
bstnA(gbl)# no policy-filename-fileset logs
 deletes a name-based fileset.
```

**Related Commands** [name](#)  
[path](#)  
[recurse](#)  
[filename-fileset](#)

---

# policy-filesize-fileset

**Purpose** Use the `policy-filesize-fileset` command to create a size-based fileset for any volume.

**Mode** `gbl`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `policy-filesize-fileset name`  
`no policy-filesize-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** `None`

**Guidelines** The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-fs-filesize` mode, where you use the [select-files \(...-fs-filesize\)](#) command to choose files larger-than (and/or smaller-than) a size of your choosing.

This type of fileset is available to all namespaces and volumes. To create a similar fileset in a single volume, use [filesize-fileset](#) in `gbl-ns-vol` mode.

You cannot remove this global fileset if any volume or rule uses it.

**Samples** `bstnA(gbl)# policy-filesize-fileset midsize`  
 This will create a new policy object.

```
Create object 'midsize'? [yes/no] yes
bstnA(gbl-fs-filesize[midsize])# ...
 defines the 'midsize' fileset. Any volume can use this size-based fileset.
```

```
bstnA(gbl)# no policy-filesize-fileset 1_to_4_gig
bstnA(gbl)# ...
 removes a filesize fileset, '1_to_4_gig.'
```

**Related Commands** [select-files \(...-fs-filesize\)](#)  
[filesize-fileset](#)

## policy-intersection-fileset

**Purpose** Use the `policy-intersection-fileset` command to create an intersection fileset. An intersection fileset contains all files that are common to all of its source filesets. Use the `no` form of the command to delete the intersection fileset.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy-intersection-fileset name`  
`no policy-intersection-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.)

An intersection fileset contains files that are common to two or more source filesets. This command places you in `gbl-fs-isect` mode; from there, use the [from fileset \(gbl-...-fs-...\)](#) command to identify each source fileset.

This command creates a fileset that is available to all namespaces and volumes. To create a similar fileset in a single volume, use [intersection-fileset](#) in `gbl-ns-vol` mode.

You cannot remove this global fileset if any volume or rule uses it.

**Samples** `bstnA(gbl)# policy-intersection-fileset xmlViaFtp`  
This will create a new policy object.

```
Create object 'xmlViaFtp'? [yes/no] yes
bstnA(gbl-fs-isect[xmlViaFtp])#
 creates an intersection fileset.
```

```
bstnA(gbl)# no policy-intersection-fileset isectTst
 removes an intersection fileset.
```

**Related Commands** [from fileset \(gbl-...-fs-...\)](#)  
[intersection-fileset](#)

---

# policy-union-fileset

**Purpose** Use the `policy-union-fileset` command to create a union fileset. A union fileset is the union of two or more component filesets.

Use the `no` form of the command to remove the union fileset.

**Mode** `gbl`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `policy-union-fileset name`  
`no policy-union-fileset name`

*name* (1-1024 characters) is the name you choose for the fileset.

**Default(s)** `None`

**Guidelines** A union fileset joins two or more source filesets into one. If a file belongs in any of the source filesets, it is also included in the union fileset.

The CLI prompts for confirmation before creating a new fileset; enter `yes` to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-fs-union` mode; from there, use the [from fileset \(gbl-...-fs-...\)](#) command to identify each source fileset.

This command creates a fileset that is available to all namespaces and volumes. To create a similar fileset in a single volume, use [union-fileset](#) in `gbl-ns-vol` mode.

You cannot remove this global fileset if any volume or rule uses it.

**Sample** `bstnA(gbl)# policy-union-fileset allLogs`  
This will create a new policy object.

```
Create object 'allLogs'? [yes/no] yes
bstnA(gbl-fs-union[allLogs])#
 creates a union fileset.
```

**Related Commands** [from fileset \(gbl-...-fs-...\)](#)  
[union-fileset](#)

## recurse

**Purpose** Use the `recurse` command to include all subdirectories in the current file-name fileset.  
Use `no recurse` to include only files in the top directory.

**Modes** `gbl-fs-name`  
`gbl-ns-vol-fs-name`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `recurse`  
`no recurse`

**Default(s)** `no recurse`

**Guidelines** Use this command to set or unset recursion. If recursion is set, the file-name fileset selects directories and/or files below the root directory. The `path` command chooses directory paths, and the `name` command chooses files.

If you use `recurse` in a fileset without any `path` or `name` specification, this selects all files in the volume.

**Sample** `bstnA(gbl-fs-name[logs])# recurse`  
includes files in all subdirectories.

**Related Commands** [policy-filename-fileset](#)  
[filename-fileset](#)  
[name](#)  
[path](#)

---

## select-files (...-fs-filesize)

**Purpose** A size-based fileset chooses a group of files based on their sizes. Use the `select-files` command to choose the sizes for the current fileset.

**Modes** `gbl-fs-filesize`  
`gbl-ns-vol-fs-filesize`

**Security Level** storage-engineer or crypto-officer

**Syntax** `select-files {larger-than-or-equal-to | smaller-than}`  
`size[k|M|G|T]`  
`no select-files {larger-than-or-equal-to | smaller-than}`

**larger-than-or-equal-to** | **smaller-than** is a required choice. This determines whether the selected files are larger or smaller than the size that follows.

*size* is the size in bytes, KiloBytes, MegaBytes, or whatever units you specify (see below).

**k|M|G|T** (optional) specifies units; **k** for KiloBytes (1024 bytes), **M** for MegaBytes (1024\*1024 bytes), **G** for GigaBytes (1024\*1024\*1024), and **T** for TeraBytes (1024\*1024\*1024\*1024). Do not put any space between the size number and this unit (for example, **100k** is valid but **100 k** is not). The default is bytes.

**Default(s)** None

**Guidelines** The `select-files` command is the only required step in configuring a size-based fileset. You can use this command twice to define a size range (for example, to select files larger than 50 MegaBytes but smaller than 1 Gigabyte). The CLI rejects a `select-files` command that contradicts an existing `select-files` command: you cannot select files “smaller-than 1 MegaByte” if you have already selected files “larger-than or equal-to 2 GigaBytes.”

**Sample** `bstnA(gbl-ns-vol-fs-filesize[midsize])# select-files`  
`larger-than-or-equal-to 20M`  
`bstnA(gbl-ns-vol-fs-filesize[midsize])# select-files smaller-than 50M`  
 selects all files that are between 20 and 50 MegaBytes.

**Related Commands** [policy-filesize-fileset](#)  
[filesize-fileset](#)

## select-files (...-fs-age)

**Purpose** An age-based fileset chooses a single group of files based on time stamps: those newer or older than a certain interval (such as “older than 1 day”) or between two intervals (for example, “newer than 2 weeks and older than 1 day”). Use the `select-files` command to set the selection criteria.

**Modes** `gbl-fs-age`  
`gbl-ns-vol-fs-age`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `select-files {older-than | newer-than} interval {minutes | hours | days | weeks | months | quarters | years}`

`no select-files {older-than | newer-than}`

**older-than | newer-than** is a required choice. This determines whether the selected files are older or newer than the time interval that follows.

**interval** (1-2,147,483,647) is the number of minutes, hours, days, etc., that selected files are older than or newer than.

**minutes | ... years** is a required choice.

**Default(s)** `None`

**Guidelines** The `select-files` command is the only required step in configuring an age-based fileset. Without any selection criteria, the fileset includes all files.

You can use this command twice to define an age range (for example, to select files older than 1 week but newer than 1 year). The CLI rejects a `select-files` command that contradicts an existing `select-files` command: you cannot select files “newer than 6 hours” if you have already selected files “older than 3 weeks.”

Each file has two time stamps: last-accessed time and last-modified time. This command measures against the time stamp selected with the `last` command.

By default, this selects from every file in the current managed volume. To limit the files to those in some other fileset (for example, to choose only from a `filename-fileset` containing `.wmv` files), use the `from fileset (gbl-...-fs-...)` command.

By default, the policy engine runs this file selection whenever it is invoked by another rule (such as a `place-rule` or a `shadow-copy-rule`). For example, if the fileset is composed of files newer than 1 month and a file-placement rule uses it on September 30, it includes all files modified since August 31. If the file-placement rule runs again on October 5, the fileset re-selects its files: at this point, it holds all files modified since September 5, 1 month before October 5. You can use the `every (...-fs-age)` command to make the file re-selections happen at a fixed rate (for example, every 2 days).

**Sample** `bstnA(gbl-ns-vol-fs-age[ns~/vol~24hrs])# select-files older-than 24 hours`  
identifies all files that are older than 24 hours in the age-based fileset.

**Related Commands** [policy-age-fileset](#)  
[age-fileset](#)

## show policy filesets

**Purpose** Use the `show policy filesets` command to view fileset configurations.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show policy filesets`  
`show policy filesets global-fileset fileset-name`  
`show policy filesets namespace namespace volume volume`  
`fileset fileset-name`

**global-fileset *fileset-name*** (optional, 1-1024 characters) focuses the command on a single, global fileset.

**namespace *namespace* volume *volume* fileset *fileset-name*** focuses on a single, volume-level fileset.

*namespace* (1-30 characters) is the fileset's namespace,

*volume* (1-1024 characters) is the fileset's volume path, and

*fileset-name* (1-1024 characters) is the fileset..

**Guidelines** If you do not enter a specific fileset, this command displays all filesets. The globally-defined filesets appear first, followed by a section for each namespace and volume. Each volume-level fileset (such as a [age-fileset](#)) appears with its volume.

For each fileset, a single Configuration table shows all of the administratively-set parameters for the fileset. You can create or edit each fileset type with a separate command:

- “Filename Fileset” with [policy-filename-fileset](#),
- “Age Fileset” with [policy-age-fileset](#),
- “Fileset Intersection” with [policy-intersection-fileset](#), or
- “Fileset Union” with [policy-union-fileset](#).

The remaining fields show the configuration parameters for the fileset, and the number of rules that use the fileset.

**Samples** `bstnA# show policy filesets`  
shows all filesets. See [Figure 26.1](#) for sample output.

`bstnA# show policy filesets global-fileset veryLarge`  
shows one globally-defined fileset, “veryLarge.” See [Figure 26.2 on page 26-31](#) for sample output.

`bstnA# show policy filesets namespace insur volume /claims fileset images`  
shows a single fileset in the “insur~/claims” volume.

**Related Commands** [policy-filename-fileset](#)

## start

**Purpose** **\*\* Deprecated \*\***  
For age-based filesets, use the **start** command to set a start time for grouping files.  
Use **no start** to select files each time a rule uses the fileset.

**Modes** gbl-fs-age  
gbl-ns-vol-fs-age

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **start** [*mm/dd/yyyy:HH:MM:SS*]  
**no start**

*mm/dd/yyyy* sets a start date (for example, **date 05/25/2003**).

*HH:MM:SS* sets a start time (for example, **06:00:00**).

**Default(s)** Whenever the fileset is used by a policy rule (such as a [place-rule](#) or a [shadow-copy-rule](#)).

**Guidelines** This command is deprecated in favor of controlling age selection from the rule's schedule. Consider instead using the [schedule \(gbl-ns-vol-plc\)](#) command (for a file-placement rule) or the [schedule \(gbl-ns-vol-shdwcp\)](#) command (for a shadow-copy rule). These assign a start time and a schedule to the rule. In most-all cases, it is more intuitive to let the rule's schedule determine start times and file selections.

**Guidelines: Effects on Time Calculations** This command sets a starting point for all age-based calculations. For example, if you have a fileset that re-evaluates **every 7 days**, this determines the starting point and the time of day for each evaluation (Mondays at 2AM, Fridays at 5PM, or some other day and time).

The evaluation chooses files that belong in the fileset. By default, this occurs at the time the fileset is used by a rule.

If you set a start date/time in the future, the fileset waits until that time to start grouping files.

**Sample** `bstnA(gbl-fs-age[month01d])# start 05/06/2003:23:00:00`  
sets a start date of May 6, 2003, at 11PM.

**Related Commands** [age-fileset](#)  
[every \(...-fs-age\)](#)

---

# union-fileset

- Purpose** Use the `union-fileset` command to create a union fileset in the current namespace volume. A union fileset is the union of two or more component filesets.  
Use the `no` form of the command to remove the union fileset.
- Mode** `gbl-ns-vol`
- Security Role(s)** `storage-engineer` or `crypto-officer`
- Syntax** `union-fileset name`  
`no union-fileset name`
- name* (1-1024 characters) is the name you choose for the fileset.
- Default(s)** `None`
- Guidelines** A union fileset joins two or more source filesets into one.  
This command creates a fileset that is only usable in the current volume. To create a global-union fileset, usable from any namespace or volume, use [policy-union-fileset](#) in `gbl` mode.  
The CLI prompts for confirmation before creating a new fileset; enter **yes** to continue. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.) This places you in `gbl-ns-vol-fs-union` mode; from there, use the [from fileset \(gbl-...-fs-...\)](#) command to identify each source fileset.
- Sample**

```
bstnA(gbl-ns-vol[ns~/vol])# union-fileset allLogs
This will create a new policy object.

Create object 'allLogs'? [yes/no] yes
bstnA(gbl-ns-vol-fs-union[ns~/vol~allLogs])#
creates a union fileset.
```
- Related Commands** [policy-union-fileset](#)  
[from fileset \(gbl-...-fs-...\)](#)

# 27

---

---

## Place Rules

---

---

Policy commands govern file migration to balance load and capacity among back-end filers.

---

## enable (gbl-ns-vol-plc)

**Purpose** Use the `enable` command to enable the current rule. A new rule is disabled by default, and the policy engine ignores disabled rules.

Use `no enable` to disable the current rule.

**Modes** gbl-ns-vol-plc

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `enable`  
`no enable`

**Default(s)** `no enable`

**Guidelines** You must enable a rule for the policy engine to use it.

**Sample** `bstnA(gbl-ns-vol-plc[archives~/multimedia~PDFs])# enable`  
enables the current file-placement rule, "PDFs."

**Related Commands** [namespace](#) -> [volume](#) -> [place-rule](#)

## from (gbl-ns-vol-plc)

**Purpose** A file-placement rule moves files onto chosen storage. Use the **from** command to select some source files to move.

Use **no from** to remove the source fileset, which effectively disables the rule.

**Mode** gbl-ns-vol-plc

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **from fileset** *fileset-name* [**match files**]  
**from fileset** *fileset-name* **match directories**  
[**promote-directories**]  
**from fileset** *fileset-name* **match all** [**promote-directories**]  
**no from**

*fileset-name* (1-1024 characters) is the name of an existing source fileset.

**match files** (optional) matches the fileset against files only, ignoring all directories. This is the default.

**match directories** (optional) matches the fileset against directories only, ignoring all files.

**promote directories** (optional) causes all migrated directories to be promoted at the target filer. Any new files or subdirectories in these directories will also go to the target filer (unless redirected by another rule).

**match all** (optional) matches both files and directories.

**Default(s)** match ... defaults to matching files only.

**Guidelines** Use this command to select particular files and/or directories to migrate. Use the [source](#) command to select only from a particular share or share farm. The placement rule migrates all matching files/directories to its [target](#) storage. Use the **no** form of the command to remove the fileset.

This command skips files with multiple Unix hard links. To migrate hard links off of a share, use the [source](#) command instead of this command. Alternatively, you can use the the [source](#) command and this command together with [migrate hard-links](#).

If a single fileset is too restrictive, use the [union-fileset](#) command to join multiple filesets into one.

The **from fileset** syntax allows you to match the fileset against files, directories, or both.

**Guidelines: Matching Files** By matching files only, you can redistribute files with certain names (such as \*.mpg) to a share or a share farm. A files-only match can also implement tiering: an [age-fileset](#) can select files in a certain age group to migrate to a certain tier (that is, a certain share or share farm). The volume creates replica directories on the destination share, called directory *stripes*, to hold the files.

**Guidelines: Matching Directories**

Each directory has one *master* copy on the share where the volume first discovered it. A directory can have no stripes or up to one stripe per remaining share in the volume. As stated above, the volume typically creates stripes to hold migrated files. If you use the `from fileset` syntax to match against `directories` only or `all` (both files and directories), you can use the `promote-directories` flag to promote the stripe on the target share to master.

To make all new directory trees grow on the target filer, use the `match directories` option without `promote-directories`. This steers all ensuing client-created directories to the target share. These new directories will exist at the target share first, where they will be master. Directory trees under those new directories will follow them to the target share. Files under the pre-existing directories will tend to stay on their source filers, since their masters remain on the source filers.

You can make whole directory trees grow at the target filer with `match directories` and `promote-directories`. This creates master copies of all matching directories at the target filer. This does not migrate any existing files, but it does steer all new files and subdirectories to the target filer. This can be useful if a `nsck ... rebuild` operation has scattered a directory tree's mastership among multiple shares.

 **Important**

*Do not match and promote directories based on their last-accessed times in a CIFS or multi-protocol volume; a CIFS filer changes the directory's time stamp whenever the time stamp itself is read.*

**Guidelines: Matching Files and Directories**

To move an existing directory tree to the target filer(s) and make it grow there, use `match all` and `promote-directories`.

**Guidelines: no from**

The `no from` command removes the only source fileset from the rule, effectively disabling it if there is no `source` to drain. The CLI prompts for confirmation before doing this; enter `yes` to proceed.

**Sample**

In `gbl-ns-vol-plc` mode, the following example selects the “`doc_files`” source fileset for the “`copytoNas206`” placement rule. It matches the fileset against files only:

```
bstnA(gbl-ns-vol[wwmed~/acct])# place-rule copytoNas206
bstnA(gbl-ns-vol-plc[wwmed~/acct~copytoNas206])# from fileset doc_files
bstnA(gbl-ns-vol-plc[wwmed~/acct~copytoNas206])# ...
```

**Related Commands** [place-rule](#)  
[target](#)

## inline notify

**Purpose** By default, a file-placement rule finds its source files by monitoring all new files as they are created, monitoring client changes as they happen (*inline*), *and* scanning the volume for existing files. Use the `no inline notify` command to disable inline-change notifications and work with new and scanned files only.  
Use the `inline notify` command to re-enable inline notifications for the current rule.

**Mode** `gbl-ns-vol-plc`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `no inline notify`  
`inline notify`

**Default(s)** `inline notify`

**Guidelines** Inline notifications happen as clients change files. Whenever a file changes so that it conforms to the source fileset, the file-placement rule migrates the file as needed. The migration is queued immediately, not the next time the rule runs. This command can disable or re-instate inline notifications to the current rule.

Whenever inline notifications are disabled, changed files do not migrate until the next time that the rule scans the volume. If no future volume scan is scheduled, the files remain indefinitely. For this reason, `no inline notify` is only recommended for a rule that has an assigned [schedule \(gbl-ns-vol-plc\)](#).

A tiered-storage configuration has multiple place rules, typically one per tier, with different recommendations for this setting. The placement rule(s) that send files to Tier 1 should have `inline notify` enabled. The rule(s) that send files to other tiers should use `no inline notify` and have an assigned schedule. This recommendation ensures that files migrate to tier 1 as soon as they are qualified for that tier, but they do not move to a lesser tier until a scheduled run of a file-placement rule. This reduces the computation load on the policy engine.

This command has no effect on placement of new files and/or directories; the rule causes these entries to be created on the target storage, so no migrations are necessary.

Volume scans are controlled by the [volume-scan](#) command.

**Sample** `bstnA(gbl-ns-vol-plc[ns3~/vol~new2shr5])# no inline notify`  
disables inline notifications to the “new2shr5” rule.

**Related Commands** [place-rule](#)  
[schedule \(gbl-ns-vol-plc\)](#)  
[volume-scan](#)

---

# inline report

**Purpose** An *inline* event is one that occurs between scheduled runs of the file-placement rule. Clients can make inline changes to files that make them eligible for migration by the file-placement rule. Use this command to enable regular inline-migration reports for the current file-placement rule, to track any inline migrations that may occur. Use `no inline report` to prevent inline-migration reports.

**Mode** gbl-ns-vol-plc

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `inline report {hourly|daily} prefix [verbose]  
[delete-empty|error-only]`

`no inline report`

*prefix* (1-1024 characters) sets a prefix for all inline-migration reports. Each report has a unique name in the following format:

*prefix\_YearMonthDayHourMinute.rpt*

For example, “tier1-inline\_200903031200.rpt” could be the name for one report with the “tier1-inline” prefix.

**verbose** (optional) enables verbose data in the reports.

**delete-empty** | **error-only** (optional) are mutually exclusive.

**delete-empty** causes the rule to delete any reports that contain no migrated files or errors.

**error-only** causes the rule to delete any reports that contain no errors.

**Default(s)** `no inline report`

**Guidelines** This command creates hourly or daily reports to track the current rule’s inline migrations. These reports can consume a great deal of internal disk space over time; you can use the `delete-empty` or `error-only` flags to conserve on this space.

Use [show reports](#) for a list of reports, or `show reports file-name` to show the contents of one report.

**Samples** `bstnA(gbl-ns-vol-plc[wwmed~/acct~docs2das8])# inline report hourly  
docsPlc verbose`  
enables hourly inline-migration reports for a file-placement rule, “docs2das8.” See [Figure 27.1 on page 27-8](#) for sample output.

`bstnA(gbl-ns-vol-plc[ns3~/usr~mp30ff])# no inline report`  
disables inline-migration reports for the “mp30ff” rule.

**Related Commands** [place-rule](#)  
[show reports](#)

## limit-migrate

**Purpose** A file-placement rule migrates files from one share to another within a managed volume. Use the `limit-migrate` command to limit the amount of data moved in this migration. If the placement rule runs on a schedule, this limit applies to each run of the rule.

Use `no limit-migrate` to remove any limit on the size of migrations.

**Mode** `gbl-ns-vol-plc`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `limit-migrate size[k|M|G|T]`  
`no limit-migrate`

*size* (1-18,446,744,073,709,551,615) is the size.

**k|M|G|T** (optional) is the units:

- **k** is kilobytes (1024 bytes),
- **M** is Megabytes (1024\*1024 bytes),
- **G** is Gigabytes (1024\*1024\*1024 bytes), and
- **T** is Terabytes (1024\*1024\*1024\*1024 bytes).

**Default(s)** `no limit-migrate`  
*size* is in bytes.

**Guidelines** The policy engine migrates as many files as possible until it reaches one that would reach or exceed this limit. If the placement rule is on a [schedule \(gbl-ns-vol-plc\)](#), the next run of the rule continues migrating any leftover files until it either finishes or reaches the limit again.

If the rule's source is a share (as opposed to a fileset), you can use this limit in conjunction with a schedule in order to gradually drain the share. For example, suppose you want to migrate 1 terabyte of files from a share, but you do not want to slow down switch processing during business hours. A schedule can run the placement rule only during off-hours, and the `limit-migrate` command can ensure that the placement rule stops after migrating a reasonable amount of storage.

**Samples** `bstnA(gbl-ns-vol-plc[wwmed~/acct~copytoNas206])# limit-migrate 35G`  
sets a migration limit of 35 Gigabytes for the "copytoNas206" rule.

`bstnA(gbl-ns-vol-plc[archives~/etc~empty])# no limit-migrate`  
removes any migration limit from the "empty" rule. This rule continues to migrate files until they are all on the target.

**Related Commands** [place-rule](#)  
[schedule \(gbl-ns-vol-plc\)](#)

---

# migrate close-file

**Purpose** A file-placement rule blocks all CIFS access from a file before it migrates it; this is impossible if another CIFS client already has the file open. You can use the `migrate close-file` command to permit the rule to automatically close any file opened through CIFS, and hold it closed until it has finished migrating.

Use `no migrate close-file` to disable the auto-close feature for the current file-placement rule.

**Mode** gbl-ns-vol-plc

**Security Level** storage-engineer or crypto-officer

**Syntax** `migrate close-file [exclude fileset]`  
`no migrate close-file`

*fileset* (optional, 1-1024 characters) is a fileset to exclude from automatic closure. If a file in this fileset is open through CIFS, the rule places it on a retry queue instead of automatically closing it.

**Default(s)** `no migrate close-file`

**Guidelines** This command is only relevant in a managed volume that supports CIFS. It has no effect on files opened through NFS.

If a CIFS client attempts to open a file while it is held closed, the client receives a sharing violation.

You can use the `show policy files-closed` command to view any files that are currently closed by file-placement rules.

If this feature is disabled, the placement rule cannot migrate any open files. You have two commands that you can use to monitor open files and close them manually: the `show cifs-service open-files` command shows all such files, and `close cifs file` closes one from the CLI.

**Samples** `bstnA(gbl-ns-vol-plc[insur~/claims~2old])# migrate close-file`  
 allows the “2old” rule to close any open files that it needs to migrate.

`bstnA(gbl-ns-vol-plc[ns3~/vol~new2shr5])# migrate close-file exclude homedirs`  
 allows the “new2shr5” rule to close any open files *except* files in the “homedirs” fileset.

**Related Commands** `place-rule`  
`show policy files-closed`  
`show cifs-service open-files`  
`close cifs file`

## migrate hard-links

**Purpose** Some Unix files have more than one *hard link*, where each hard link is a different file name (often in a different directory) pointing to the same inode. A file-placement rule typically skips all files with multiple hard links. If your site has many such files and you are migrating a fileset off of a single [source](#) share, you can use the `migrate hard-links` command to migrate all hard links. If one of a file's hard links matches the fileset, this command causes the rule to migrate all of the file's hard links off of the source share.

Use `no migrate hard-links` to stop migrating any files with multiple hard links.

**Mode** `gbl-ns-vol-plc`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `migrate hard-links`  
`no migrate hard-links`

**Default(s)** `no migrate hard-links`

**Guidelines** This only applies to a namespace that supports NFS, where the back-end filers have Unix file systems. This has no effect in a CIFS-only namespace.

The file-placement rule must have a single [source](#) share and a fileset (identified with [from \(gbl-ns-vol-plc\)](#)) for this command to function. Additionally, no other [place-rule](#) can use the same source share. These rules minimize contention between conflicting file-placement rules, and are enforced by the CLI.

An inline event (see [inline notify](#)) is not guaranteed to trigger migration of a multi-hard-link file. To guarantee that all matching multi-link files migrate off of the source share, turn off inline notifications (with `no inline notify`), assign a [schedule \(gbl-ns-vol-plc\)](#) to the rule, and wait for the next scheduled run of the rule.

If any hard link is outside the source share on the back-end filer, the file-placement rule cannot possibly find that link. The rule skips all such external hard links.

A file-placement rule already migrates all hard links, regardless of this setting, if it is designed to drain a share or share farm. Such a rule has a setting for [source](#) but no fileset designated with [from \(gbl-ns-vol-plc\)](#).

**Sample** `bstnA(gbl-ns-vol-plc[insur~/claims~old2new])# migrate hard-links`  
allows the "old2new" rule to migrate all of a file's hard links if any of them match.

**Related Commands** [place-rule](#)  
[source](#)  
[from \(gbl-ns-vol-plc\)](#)  
[inline notify](#)

---

## migrate retain-files

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Policy rules can migrate files off of the share; to retain a copy of all migrated files in a hidden directory, use the <code>migrate retain-files</code> command.<br>Use the <code>no</code> form of the command to stop retaining copies of migrated files.                                                                                                                                                                                                                                                                                                                |
| <b>Modes</b>            | gbl-ns-vol-shr                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>           | <code>migrate retain-files</code><br><code>no migrate retain-files</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Guidelines</b>       | If this command is enabled, all files migrate off of the current share are also copied into the “~acopia_msnap” directory in the root of the share.<br><br>We recommend that you only use this before using <a href="#">remove-share migrate</a> or a <a href="#">place-rule</a> to migrate all files off of the share. You can use the directory tree as a backup in case you are dissatisfied with the results of the migration. To restore the files after a migration, you must access the filer directly (the directory is named so that the volume cannot import it). |
|                         | <p><b>◆ Important</b></p> <hr/> <p><i>Do not use this in a <a href="#">share-farm</a> with a <a href="#">balance</a> or <a href="#">auto-migrate</a> rule enabled. The policy engine may attempt to migrate files off of the share, and this command would prevent file migration from ever changing the free space on the share. This leads to the policy engine continually migrating files to other shares in the share farm.</i></p> <p>This feature cannot function if the backing share contains two or more NetApp qtrees.</p>                                       |
| <b>Sample</b>           | <code>bstnA(gbl-ns-vol-shr[wwmed~/acct~bills])# migrate retain-files</code><br>keeps a copy of any file that policy migrates off of the “bills” share.                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Guidelines</b>                   | <p>When you create a new place-rule, the CLI prompts for confirmation. Enter <b>yes</b> to create the rule. (You can use <a href="#">terminal expert</a> to eliminate confirmation prompts for creating new policy objects.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Guidelines: Simple Placement</b> | <p>This command places you in <code>gbl-ns-vol-plc</code> mode, where you choose the source files and the destination storage. This rule dynamically places chosen files and/or directories onto chosen storage devices. Use the <a href="#">from (gbl-ns-vol-plc)</a> command to select a source fileset; you have options to determine whether to match the fileset against files, directories, or both, and you can determine whether any matching directories should be promoted to “master” on the target storage. Use the <a href="#">target</a> command to select a destination share farm or share for the files.</p> <p>To start migrating the files, or to start a “tentative” simulation (described below), use the <a href="#">enable (gbl-ns-vol-plc)</a> command.</p> <p>This scans all files in the volume (or a subset of source shares), determines which files or directories belong in the fileset, and immediately migrates them to the target share or share farm. It only needs to run once if it places files based on their names or their sizes. Newly-created files are assessed at creation time and placed according to this rule. Files changed “inline” by clients are assessed when they change; if they now match the fileset, they migrate immediately after the change.</p> <p>You can use the <a href="#">show statistics migration</a> command to track all migration activity.</p> |

**Guidelines:  
Scheduling for an  
Age-Based Fileset  
(Tiering)**

If the placement rule uses a [age-fileset](#), you need a [schedule \(gbl-ns-vol-plc\)](#) to re-assess the fileset as time goes on. Each time the schedule fires, the fileset gathers a new set of files based on that scheduled time. For example, consider a fileset where files are 2 weeks old; on 9/30, those are files modified before 9/16, but on 10/1 the set includes all files modified before 9/17. A daily schedule would expand the set by one day as each day passes. A weekly schedule would expand the set by a full week as each week passes: on 9/30, the “2-week-old” set is anything modified before 9/16, on 10/1 it is still “anything modified before 9/16,” and the set remains that way until the schedule fires again on 10/6. On 10/6 the schedule fires and the fileset becomes “anything modified before 9/23” (2 weeks before 10/6).

Use this for creating tiers of storage in your volume. For example, if you want files older than 3 months to move to your Tier-2 shares, use an age-based fileset and a schedule to determine how frequently to re-assess the file ages and move them to the second tier.

**Guidelines:  
Scheduling for a  
CIFS-Attribute Fileset**

Some placement rules use a [policy-cifs-attributes-fileset](#), which checks the setting of the *offline* attribute on each file. If the attribute is set, the file is actually a stub with most of its content archived on another server. The attribute is governed by a Hierarchical Storage Management (HSM) system on the back-end filer, not by client action. The policy engine must scan the back-end filers to detect this attribute setting, and it must re-scan to see if the attribute changed. To make the rule periodically re-scan and discover any changes in this type of fileset, use a [schedule \(gbl-ns-vol-plc\)](#).

**Guidelines:  
Scheduling for Other  
Filesets**

The optional [schedule \(gbl-ns-vol-plc\)](#) command has limited uses for non age-based and non-CIFS-attribute filesets. As mentioned above, these filesets are static, and a file-placement rule migrates them to their target share(s) continuously, as they are created or modified.

You typically need a schedule only for very-large filesets of this type, filesets so large that they require days for the initial migration. For these filesets, you can use the [limit-migrate](#) command to limit the size of each migration or the [duration](#) command to limit the time.

One other occasion for a schedule is a file-placement rule with a [no inline notify](#) setting. A client creates an *inline* change by editing a file or directory. The rule software receives a notification of the change by default, and immediately migrates the changed file if its new name or size places it into the fileset. With inline notifications disabled, the volume may accumulate changed files that break the current placement rule. You can use a schedule to periodically migrate these changed files to their desired share(s).

**Guidelines:  
Configuration  
Changes in a  
Scheduled Rule**

If you make a configuration change in a rule that is running with a schedule, the configuration change is ineffective until the next time the rule runs. This includes changes to the rule’s behavior between scheduled runs, such as a change to [inline notify](#) behavior. You can make a change effective immediately by running [no enable \(gbl-ns-vol-plc\)](#) followed by [enable](#) on the rule.

**Guidelines: Draining a  
Share or Share Farm**

You can drain all files and directories from a share or share farm by specifying a [source](#) share or share farm without using the [from \(gbl-ns-vol-plc\)](#) command to specify particular files or directories. After draining all of the files off of a share, you can wait for all of the volume’s snapshot rules ([snapshot rule](#)) to age out, and then you can remove the shares from the managed volume ([remove-share nomigrate](#) or [remove-share migrate](#)).

- Guidelines: Migrating a Closed File in a CIFS Volume** The [migrate close-file](#) command enables the rule to close any file that is opened through CIFS. A rule with this setting can hold the file closed until the migration is finished. Without this setting, the rule cannot migrate an open file if it remains open for the duration of the overall migration run.
- Guidelines: Migrating Files with Multiple Hard Links** A file-placement rule typically skips files with multiple Unix hard links. To migrate hard links off of a share, use [migrate hard-links](#) together with [source](#) and [from \(gbl-ns-vol-plc\)](#). Alternatively, you can use the [source](#) command alone (without [from \(gbl-ns-vol-plc\)](#) or [migrate hard-links](#)) to drain all files off of the share, including files with multiple hard links.
- Guidelines: Other Options** To enable report-generation for each file-placement session (recommended), use the [report \(gbl-ns-vol-plc\)](#) command.
- You have the option to set [migrate retain-files](#) for the source share(s) before you enable the rule. This keeps copies of all the migrated files in a hidden directory at the root of the share(s). You can use these copies to recover from a failed migration.
- You can make the rule simulate a migration with the [tentative](#) command. This causes the rule to log all migrations to the syslog as “tentative,” without actually migrating any files. This is useful for gauging the effects of a potential file migration.
- To wait for a particular migration to finish (for example, as part of a CLI script), you can use the [wait-for migration](#) command.
- Guidelines: Minimum Free Space on Shares** You can use the [policy freespace](#) command to determine the amount of free space to maintain on a given share. If the place rule encounters a file that would break this restriction, the rule pauses until the share’s free space rises back up to a *resume-migrate* threshold (also set with the [policy freespace](#) command). The volume software probes the back-end share for available free space every 15 seconds. If some other rule migrates files away from the share until its free space rises to the *resume* level, the place rule continues migrating files onto the share.
- If the rule encounters a file big enough to fill the share while the share is still above the *resume* level, the rule skips the file and tries another file. If the next file fits, the place rule migrates the file. Otherwise, the place rule skips that file, too. This continues until the share’s free space drops below the *resume* level, or until the rule runs out of files to migrate. Once the free space is below the *resume* level, the migrations proceed as described above: a large enough file causes the rule to pause and wait for the free space to rise back up to the *resume* level.
- Guidelines: Multi-Protocol Restrictions** A directory in a multi-protocol (NFS and CIFS) share cannot migrate if it has an NFS-only name; the volume cannot access the directory through CIFS to replicate its CIFS attributes. The [nsck ... report inconsistencies ... multi-protocol](#) command finds all of the NFS-only names in a multi-protocol volume. You can access the volume through an NFS export and rename the NFS-only directory, or you can temporarily turn off [strict-attribute-consistency](#) at the destination share(s).
- Guidelines: Rule Order for Fileset Placement** It is possible to configure multiple fileset-placement rules that, to some extent, contradict one another. For example, one rule could place all .xml files onto Share A, while another places all files that have not been accessed in over a month onto share B. If a .xml file exists that has not been accessed in over a month, both placement rules are in contention for that file. By default, the first-configured rule places the file. You can view and change this rule order: use the [show policy namespace](#) command to see the current rule order, and use the [policy order-rule](#) command to change it.

---

**Sample** `bstnA(gbl-ns-vol[wwmed~/acct])# place-rule copytoNas206`  
This will create a new policy object.

Create object 'copytoNas206'? [yes/no] **yes**  
`bstnA(gbl-ns-vol-plc[wwmed~/acct~copytoNas206])# ...`  
instantiates a new placement rule, "copytoNas206," in the current namespace volume.

## policy freespace

**Purpose** Whenever a rule migrates a file to a share, it checks the share's free space against two thresholds. Each share has a threshold of free space to *maintain*, as well as another (typically larger) threshold of free space called a *resume* threshold. If the file would reduce the share's free space below the *maintain* level, the rule waits until the free space rises to the *resume* level before continuing. Use the `policy freespace` command to set these free-space thresholds for the current share.

Use `no policy freespace` to return to the defaults.

**Mode** gbl-ns-vol-shr

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy freespace maintain{k|M|G|T} resume-migrate  
resume{k|M|G|T}`

`policy freespace percent maintain-pct resume-migrate resume-pct`

`no policy freespace`

*maintain* is the amount of free space to maintain on this share.

**k|M|G|T** chooses the unit of measure: **k**ilobytes, **M**egabytes, **G**igabytes, or **T**erabytes. A kilobyte is 1,024 bytes, a megabyte is 1,024 kilobytes (1,048,576 bytes), and so on..

*resume* is a free-space level for resuming migrations to this share. The policy engine uses this value if the share has reached its *maintain* value; no rule can migrate to the share until its free space rises back to the *resume* level.

**percent** (optional) indicates that you are using disk-space percentages for these values instead of specific size measures.

*maintain-pct* (1-100) expresses the *maintain* value as a percentage of the overall share size.

*resume-pct* (1-100) is the *resume* threshold, expressed as a percentage of the share's total space.

**Default(s)** *maintain* - 1G

*resume* - 2G

**Guidelines** A rule that is migrating files to this share (such as a [place-rule](#), or a share farm’s [auto-migrate](#) directive) checks each file before migrating it. If the file would reduce the share’s free space below the level that the share is supposed to maintain, the rule pauses and sets its status to “Target Full.” The rule determines its next steps based on the share’s current level of free space.

- If the share’s space is below the *resume* level, the rule stops migrating. Instead, the rule waits for the share’s free space to rise back up to its resume-migrate level. Some other rule must migrate files off of the share to achieve this. The volume software probes the back-end share for free-space every 15 seconds.
- If the share’s space is already above the *resume* level, the rule does not wait for the share’s free space to rise; the share’s free space is already high enough to resume migrating to it. The rule skips the file and moves on to the next one. If the next file fits onto the share while maintaining the required free space, the rule migrates the file. Otherwise, the rule skips the file and moves on to another file. The rule continues migrating and/or skipping files until the share’s free space is below its resume level, or until it runs out of files to migrate. If the share’s space falls below the resume level, it follows the process above.

Detailed output from [show policy](#) shows the number of files skipped along with their total disk space. If the migrating rule is a [place-rule](#) with verbose reports enabled ([report \(gbl-ns-vol-plc\)](#)), the report lists all of the skipped files.

A share farm also follows the share’s free-space thresholds. If a share is at or below the free space that it should maintain, it cannot receive new files from a [balance](#) rule.

To run this command on every share in a namespace, volume, or share farm, you can use the macro version of this command in one of their CLI modes. See the documentation for [policy freespace \(gbl-ns, gbl-ns-vol\)](#) or [policy freespace \(gbl-ns-vol-sfarm\)](#).

**Samples** `bstnA(gbl-ns-vol-shr[medarcv~/rcrds~rx])# policy freespace 4G  
resume-migrate 5G`

makes the policy engine maintain at least 4 Gigabytes of free space on the “rx” share. If that limit is reached by clients or approached by a migration rule, the share is ineligible for any more migrations until its free space rises back up to 5 Gigabytes.

`bstnA(gbl-ns-vol-shr[medarcv~/rcrds~bulk])# no policy freespace`  
reverts the “bulk” share to the default thresholds for free space.

**Related Commands** [namespace](#) -> [volume](#) -> [share](#)  
[place-rule](#)  
[show policy](#)  
[policy freespace \(gbl-ns, gbl-ns-vol\)](#)  
[policy freespace \(gbl-ns-vol-sfarm\)](#)

## policy freespace (gbl-ns, gbl-ns-vol)

**Purpose** Whenever any rule migrates a file to a share, it checks the share's free space against two thresholds. Each share has a minimum free space to *maintain*, as well as another (typically larger) level of free space called a *resume* threshold. If the file would reduce the share's free space below the *maintain* level, the rule waits until the free space rises to the *resume* level before migrating any more files to the share. The [policy freespace](#) command sets these free-space thresholds for an ARX share. Use this [policy freespace](#) command, from `gbl-ns` or `gbl-ns-vol` mode, to set the same thresholds for every share in the current namespace or volume.

Use `no policy freespace` to return to the defaults for every share in the current namespace or volume.

**Modes** `gbl-ns`  
`gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `policy freespace maintain{k|M|G|T} resume-migrate resume{k|M|G|T}`

`policy freespace percent maintain-pct resume-migrate resume-pct`

`no policy freespace`

*maintain* is the amount of free space to maintain on these shares.

`k|M|G|T` chooses the unit of measure: **k**ilobytes, **M**egabytes, **G**igabytes, or **T**erabytes. A kilobyte is 1,024 bytes, a megabyte is 1,024 kilobytes (1,048,576 bytes), and so on..

*resume* is a free-space level for resuming migrations to any of these shares. The policy engine uses this value if one of the shares has reached its *maintain* value; no rule can migrate to such a share until its free space rises back to the *resume* level.

**percent** (optional) indicates that you are using disk-space percentages for these values instead of specific size measures.

*maintain-pct* (1-100) expresses the *maintain* value as a percentage of the overall share size.

*resume-pct* (1-100) is the *resume* threshold, expressed as a percentage of the share's total space.

**Default(s)** *maintain* - 1G  
*resume* - 2G

**Guidelines** This is a macro command for the [policy freespace](#) command in `gbl-ns-vol-shr` mode. This command invokes the individual [policy freespace](#) command for every share in the current namespace or volume. The output from [show global-config](#) shows the individual share-level [policy freespace](#) commands, not this macro command.

This is similar to the [policy freespace \(gbl-ns-vol-sfarm\)](#) command, a macro command for a share farm.

**Samples** `bstnA(gbl-ns-vol[medarcv~/rcrds])# policy freespace percent 5  
resume-migrate 6`

makes the policy engine maintain at least 5-percent free space on every share in the “medarcv~/rcrds” volume. If that limit is reached by clients or approached by a migration rule on any of these shares, the share is ineligible for any more migrations until its free space rises back up to 6 percent.

`bstnA(gbl-ns[insur])# no policy freespace`

reverts all shares in the “insur” namespace to the default free-space thresholds.

**Related Commands** [namespace](#) -> [volume](#) -> [share](#)  
[policy freespace](#)  
[policy freespace \(gbl-ns-vol-sfarm\)](#)  
[place-rule](#)  
[show policy](#)

## policy migrate-attempts

**Purpose** The policy engine tries to migrate each file a limited number of times. Use the `policy migrate-attempts` command to set the migration-attempt limit for this namespace. Use `no policy migrate-attempts` to return to the default.

**Modes** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy migrate-attempts {count | unlimited}`  
`no policy migrate-attempts`

*count* (1-1000) is the total number of attempts for a failed migration before declaring that the migration failed.

**unlimited** (optional) causes the policy engine to infinitely retry its failed migrations.

**Default(s)** 32

**Guidelines** The default is adequate for most installations. Change this only on the advice of F5 personnel.

Each file migration fails individually; if one file exhausts its `migrate-attempts`, its failure does not affect any other files in the same fileset or on the same source share. If the migration runs on a [schedule](#), the migration may succeed on the next scheduled run.

Use the [policy migrate-retry-delay](#) command to set the time between retries. If any file is waiting for the policy engine to retry its migration, it is kept in a queue until it successfully migrates; use [show policy queue](#) to see all the files in this queue.

**Samples** `bstnA(gbl-ns[medarcv])# policy migrate-attempts 100`  
allows the policy engine to attempt file migrations 100 times in the “medarcv” namespace.

`bstnA(gbl-ns[wwmed])# no policy migrate-attempts`  
allows 32 attempts for file migrations in the “wwmed” namespace.

`bstnA(gbl-ns[wwmed])# policy migrate-attempts unlimited`  
allows an infinite number of migration attempts in the “wwmed” namespace.

**Related Commands** [namespace](#)  
[policy migrate-retry-delay](#)  
[show policy queue](#)

---

# policy migrate-delay

**Purpose** The policy engine does not migrate a file that has been very-recently modified. This is because clients and client applications tend to perform writes in batches; if a write occurred very recently, a new write is likely to occur very soon. You can set the amount of time since the last write, called the *migration delay*, that a file requires to be eligible for migration. Use the `policy migrate-delay` command to set the migration delay for this namespace.

Use `no policy migrate-delay` to return to the default.

**Modes** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy migrate-delay seconds`  
`no policy migrate-delay`

*seconds* (0-1000) is the delay required after the last write. Before this time elapses, the file is ineligible for migration.

**Default(s)** 30 (seconds)

**Guidelines** The default is adequate for most installations. Change this only on the advice of F5 personnel.

If the migration fails because the delay time has not yet elapsed for the file, the policy engine periodically retries. It retries every *n* seconds, where *n* is the number that you set with this command.

**Samples** `bstnA(gbl-ns[insur])# policy migrate-delay 60`  
stops the policy engine from migrating any file that has been modified 60 seconds ago (or less than 60 seconds ago).

`bstnA(gbl-ns[medarcv])# no policy migrate-delay`  
reverts to the default migration-delay time in the “medarcv” namespace.

**Related Commands** [namespace](#)

## policy migrate-method

**Purpose** The policy engine migrates files by transferring them to a hidden staging area on the target share, and then moving the file to its final destination after the network transfer is complete. This method allows large files to migrate successfully during one or more ARX-snapshot operations. It also creates a small performance penalty, one that is more noticeable when migrating a large number of small files. You can use the `policy migrate-method direct` command to choose the direct method, which allows migrations to be severely disrupted by snapshots but offers better performance in some deployment scenarios.

The `direct` method of migration is not recommended. Use `policy migrate-method staged` (or `no policy migrate-method`) to return to the default `staged` migration method.

**Modes** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `policy migrate-method {direct | staged}`  
`no policy migrate-method`

`direct` | `staged` is a required choice.

**direct** makes the policy engine migrate all of its files directly to their destinations. If a snapshot occurs in the middle of a direct migration, the migration is cancelled and must be restarted from the beginning on any later migration attempt. If the file is large enough to require a very long migration time, regular snapshots could prevent the file from ever fully migrating. However, direct migrations are sometimes faster than staged migrations, especially in a volume that migrates large numbers of small files.

**staged** makes the policy engine migrate each file to a hidden staging area at the destination share, and then move the file to its final name and location. This method succeeds while the volume is taking snapshots, with a minor performance penalty.

**Default(s)** `staged`

**Guidelines** The default is adequate for most installations. Change this only on the advice of F5 personnel. If you use this command to change to the `direct` method, snapshots severely disrupt file migrations. (Snapshots are configured with a [snapshot rule](#) in the volume.)

The `direct` method also creates a larger problem for the following scenario:

- a file is in the middle of migrating, with the original file on the source share and a partial copy of the file on the destination share, and
- the volume has a catastrophic failure, necessitating a full rebuild (similar to a [nsck ... rebuild](#)).

After this failure, the file collides with its partial copy during the subsequent re-import. The collision either causes the re-import to fail or it causes one of the file's instances to be renamed (as determined by the [reimport-modify](#) setting).

**Sample** `bstnA(gbl-ns-vol[medarcv~/rcrds])# policy migrate-method staged`  
returns the “medarcv~/rcrds” volume to the default method for migrations,  
staged.

**Related Commands** [namespace](#) -> [volume](#)  
[snapshot rule](#)

## policy migrate-retry-delay

**Purpose** When the policy engine tries and fails to migrate a file (for example, because the file is open on the back-end CIFS share), the engine waits for a short time before it tries the migration again. Use the `policy migrate-retry-delay` command to set the delay between retries.

Use `no policy migrate-retry-delay` to return to the default delay.

**Modes** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy migrate-retry-delay seconds`  
`no policy migrate-retry-delay`

*seconds* (0-1000) is the number of seconds between migration retries.

**Default(s)** 900 (seconds, or 15 minutes)

**Guidelines** The default is adequate for most installations. Change this only on the advice of F5 personnel.

Use the `policy migrate-delay` command to set the maximum number of retries. If any file is waiting for the policy engine to retry its migration, it is kept in a queue until it successfully migrates; use `show policy queue` to see all the files in this queue.

**Samples** `bstnA(gbl-ns[medarcv])# policy migrate-retry-delay 300`  
allows 300 seconds (5 minutes) between migration retries in the “medarcv” namespace.

`bstnA(gbl-ns[insur])# no policy migrate-retry-delay`  
returns to the default migration-retry delay in the “insur” namespace.

**Related Commands** `namespace`  
`policy migrate-delay`  
`show policy queue`

---

## policy order-rule

**Purpose** All rules are given a rule priority as they are created, depending on the rule's type and creation time. If two file-placement rules contradict for a given file, the rule with the higher priority is enforced and the other rule is ignored. Use the `policy order-rule` command to change a rule's priority.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy order-rule rule1 {before | after} rule2`  
`policy order-rule rule1 {first | last}`

*rule1* (1-1024 characters) is the name of the rule to move.

**before** | **after** is a required choice; this determines if *rule1* is ordered before or after *rule2*.

*rule2* (1-1024 characters) does not move. This is used to set the new priority for *rule1*.

**first** | **last** sets an absolute priority for *rule1*.

**Default(s)** None

**Guidelines** The order/priority for most rules is set at creation time, according to the following order:

1. All [shadow-copy-rules](#).
2. All [place-rules](#) that use a share (without any fileset) as their source.
3. All [place-rules](#) that use a fileset as their source.
4. All [share-farms](#).

Within each group of rules, the individual rules are ordered by their creation times.

You can only reorder the rules in the third category, file-placement rules that use a fileset as their source. The other rules have their order permanently set. Use [show policy namespace](#) to see the current rule order.

The moving rule (*rule1*) must go to the other side of the stationary rule (*rule2*), or the order does not change. For example, if you want to move ruleA to be just before ruleD, you must phrase the command this way: **policy order-rule ruleA after ruleC**.

Nothing happens if you say **policy order-rule ruleA before ruleD** because ruleA is already before ruleD.

**Samples** `bstnA(gbl-ns-vol[ns~/])# policy order-rule mytest after archiveOldFiles`  
 moves the "mytest" file-placement rule after the "archiveOldFiles" rule.

`bstnA(gbl-ns-vol[ns~/])# policy order-rule wmv2nas3 last`  
 moves the "wmv2nas3" file-placement rule to the end of the list.

**Related Commands** [namespace](#) -> [volume](#)  
[place-rule](#)  
[shadow-copy-rule](#)  
[share-farm](#)  
[show policy](#)

---

## policy pause

**Purpose** You can use the `policy pause` command to stop all volume scans and migrations in a managed volume. This can be useful during a storage maintenance procedure, such as a volume backup.

Use the `no` form of the command to resume all scans and migrations.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `policy pause namespace namespace volume volume`  
`no policy pause namespace namespace volume volume`

*namespace* (1-30 characters) identifies the namespace.

*volume* (1-1024 characters) is the volume where you want to pause all rules.

**Default(s)** `None`

**Guidelines** This command suspends all migrations and filer scans for a volume. While policy is paused, clients may change files and/or directories so that they should be migrated according to the volume's rules; the volume software notes these changes and performs the migrations after you use `no policy pause`.

A file-placement rule causes all *new* files and directories to be created on their configured back-end shares, without performing any migrations. New files and directories therefore continue to be placed according to your rules while the volume has policy paused.

As an alternative, you can set a schedule for pausing policy in a volume. This is useful for suspending migrations during schedule backup windows, for example. Use the [policy pause \(gbl-ns-vol\)](#) command for scheduled pauses.

**Samples** `bstnA# policy pause namespace insur volume /claims`  
pauses all rules in the "insur~/claims" volume.

`bstnA# no policy pause namespace insur volume /claims`  
resumes policy processing for the same volume.

**Related Commands** [policy pause \(gbl-ns-vol\)](#)

## policy pause (gbl-ns-vol)

**Purpose** You can use this `policy pause` command to regularly pause all policy processing in the current volume, according to a fixed schedule.

Use the `no` form of the command to stop pausing policy on a scheduled basis.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy pause schedule-name`  
`no policy pause`

*schedule-name* (1-64 characters) is a schedule to use for pausing all rules.

**Default(s)** None

**Guidelines** Before you use this command, someone must create a [schedule](#) for pausing policy in the current volume. This schedule must have a [duration](#) so that policy is not paused indefinitely.

This command assigns a schedule for pausing policy in the current volume. You can use this to suspend all rules on a regular basis, perhaps so that they run during off-hours.

When policy is paused for the volume, the volume suspends all migrations and filer scans. During the pause, clients may change files and/or directories so that they should be migrated according to the volume's rules; the volume software notes these changes and performs the migrations after the [duration](#) expires in the schedule.

A file-placement rule causes all *new* files and directories to be created on their configured back-end shares, without performing any migrations. New files and directories therefore continue to be placed according to your rules while the volume has policy paused.

As an alternative, you can use the `priv-exec policy pause` command to pause policy manually.

**Samples** `bstnA(gbl-ns-vol[medarcv~/rcrds])# policy pause midday`  
assigns the "midday" schedule to control policy pauses in the "medarcv~/rcrds" volume.

`bstnA(gbl-ns-vol[ns2~/movies])# no policy pause`  
disables scheduled pauses for the rules in the "ns2~/movies" volume.

**Related Commands** [namespace](#) -> [volume](#)  
[schedule](#)  
[duration](#)  
[policy pause](#)

---

# policy treewalk-threads

**Purpose** A *treewalk* is a full examination of all files and directories in a back-end share. For performance reasons, each of the namespace's volume groups uses a small pool of software threads to perform all of its treewalks. The number of simultaneous treewalks in each volume group is equal to the number of threads in the pool; this can create a bottleneck in volume groups with many managed volumes. Use the `policy treewalk-threads` command to change the number of threads for each of the namespace's volume groups.

Use the negative form of the command, `no policy treewalk-threads`, to revert to the default number of threads.

**Modes** gbl-ns

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy treewalk-threads thread-count`  
`no policy treewalk-threads`

*thread-count* (1-10) is the number of threads to use for treewalk operations. This is the thread count for each volume group in the namespace.

**Default(s)** 4

**Guidelines** The default is adequate for most installations. Change this only on the advice of F5 personnel.

Many rules and filesets require treewalks; to preserve CPU cycles, a small pool of threads performs all treewalks for each volume group.

Each of the namespace's volume groups gets this pool of threads, to be shared among all volumes in that group. (You can use the [volume-group](#) command to assign a volume to a particular group.)

Filesets that are based on file timestamps (such as the [age-fileset](#)) require a treewalk every time a rule invokes one of them. If more than four volumes use these filesets at the same time on the same volume group, only four volumes at a time can perform their treewalks. A fifth volume's treewalk cannot begin until one of the first four treewalks is finished. Two filesets in the same volume can share the results of a single treewalk, but two filesets from different volumes cannot.

You can use this command to expand the thread pools for a namespace with many age filesets, minimizing this performance issue. This change only takes effect the next time you enable the namespace. Use [enable \(gbl-ns, gbl-ns-vol\)](#) to enable the namespace.

**Sample** `bstnA(gbl-ns[wwmed])# policy treewalk-threads 5`  
 uses 5 threads for treewalking in the "wwmed" namespace.

**Related Commands** [namespace](#)  
[enable \(gbl-ns, gbl-ns-vol\)](#)  
[policy-age-fileset](#)  
[age-fileset](#)

## remove namespace ... policy-only

**Purpose** Use the `remove namespace ... policy-only` command to remove all policy objects from a namespace or volume.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `remove namespace name [volume volume] policy-only [sync]`

*name* (1-30 characters) identifies the namespace.

*volume* (optional, 1-1024 characters) focuses on a single volume.

**policy-only** causes the command to remove rules, filesets, and all other policy objects from the namespace or volume. The volume and namespace configurations remain.

**sync** (optional) shows the operation's progress at the command line. With this option, the CLI prompt does not return until all policy components have been removed.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before removing any policy objects; enter **yes** to proceed.

By default, this command generates a report to show all of the actions it takes to remove the volume(s), in order. The CLI shows the report name after you issue the command, and then returns. You can enter CLI commands as the namespace software removes the objects in the background. Use [tail](#) to follow the report as it is written. Use [show reports file-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the `copy` or `delete` commands. Use the `sync` option to send the status to the command line instead; the command does not generate a report if you use the `sync` option.

Use [remove namespace](#) to remove an entire namespace or volume, including all policy objects. To remove a namespace and all other configuration objects dedicated to the namespace (including global servers and external filers), use [remove service](#). To remove a share from a volume, use [remove-share migrate](#) or [remove-share nomigrate](#). The `remove namespace ... volume ... exports-only` command finds all front-end exports for a volume and removes them, leaving the volume itself intact.

**Sample**

```
prtlnDA# remove namespace insur_bkup policy-only sync
```

```
Remove policy components from namespace 'insur_bkup'? [yes/no] yes
% INFO: Removing service configuration for namespace insur_bkup
% INFO: Removing CIFS browsing for namespace insur_bkup
% INFO: Removing volume policies for namespace insur_bkup
% INFO: destroy policy insur_bkup /insurShdw
```

removes all policy objects from the "insur\_bkup" namespace. This uses the `sync` option, so the progress report appears on the command line instead of a file.

remove namespace ... policy-only

**Related Commands** [remove namespace](#)  
[remove service](#)  
[remove namespace ... volume ... exports-only](#)  
[remove-share migrate](#)  
[remove-share nomigrate](#)

## report (gbl-ns-vol-plc)

**Purpose** Use this command to enable progress reports for the current file-placement rule.  
Use `no report` to prevent progress reports.

**Mode** gbl-ns-vol-plc

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `report file-prefix [verbose] [delete-empty|error-only]`  
`no report`

*file-prefix* (1-1024 characters) sets a prefix for all file-placement reports. Each report has a unique name in the following format:

*prefixYearMonthDayHourMinute.rpt*

For example, `wmv2sol_200403031200.rpt` could be the name for one report with the “`wmv2sol_`” prefix.

**verbose** (optional) enables verbose data in the reports.

**delete-empty | error-only** (optional) are mutually exclusive.

**delete-empty** causes the rule to delete any reports that contain no migrated files or errors.

**error-only** causes the rule to delete any reports that contain no errors.

**Default(s)** no report

**Guidelines** Every time the file-placement rule fires and migrates files to the target storage, the rule can generate a report to show the details of the migration. The reporting feature is disabled by default; we recommend that you enable reporting for all file-placement rules, to keep track of file migrations between your back-end filers.

The rule only generates a report if at least one existing file is migrated. It does not report on placement of new files, created by clients through the VIP.

Use [show reports](#) for a list of reports, or `show reports file-name` to show the contents of one report.

**Samples** `bstnA(gbl-ns-vol-plc[medarcv~/rcrds~dailyArchive])# report  
daily_archive`

enables reports for the file-placement rule, “dailyArchive.” See [Figure 27.2 on page 27-35](#) for sample output.

`bstnA(gbl-ns-vol-plc[archives~/etc~wmv2sfarm1])# report wmv2sf1 verbose`  
enables verbose reports for the file-placement rule, “wmv2sfarm1.”

`bstnA(gbl-ns-vol-plc[ns3~/usr~mp30ff])# no report`  
disables reports for the “mp30ff” rule.

**Related Commands** [place-rule](#)

---

# show policy

**Purpose** Use the show policy command to view policy configurations.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator

**Syntax** `show policy [details]`  
`show policy namespace namespace [details]`  
`show policy namespace namespace volume volume [details]`  
`show policy namespace namespace volume volume rule rule-name`

**details** (optional) changes the output into a detailed view of each rule and share farm. If you omit this, the output is one line per rule or share farm.

**namespace** (1-30 characters) focuses the command on a single namespace.

**volume** (1-1024 characters) narrows the scope of the command to one volume in the namespace.

**rule-name** (1-1024 characters) narrows the scope even further, to one rule or share farm in the volume. This expands the output to show detailed information and statistics about the rule or share farm.

**Guidelines** This shows all namespace policies. Use [show policy](#) to show all globally-defined filesets, and use [show schedule](#) to show all globally-defined schedules. To see the history of policy-related events for a volume, rule, or share farm, use [show policy history](#). The [show policy queue](#) command shows all files currently waiting to be migrated, if any.

**Guidelines: Output** The simplest syntax, `show policy`, outputs tables of the rules and share farms in each volume. Each volume has its own table with the following labels:

Namespace and

Volume.

Each rule or share farm appears on a separate line in the volume's table, with the following fields:

Rule (the name of the rule or share farm),

Type (Place for a [place-rule](#), Share Farm for a [share-farm](#), Snapshot for a [snapshot rule](#), Replica Snapshot for a [snapshot replica-snap-rule](#), Shadow Copy for a [shadow-copy-rule](#), AutoDiagnostics for an [auto-diagnostics](#) rule, Config Replication for a [config-replication](#) rule, and Notification for a [notification rule](#)), and

Status for the rule. For most rules, this is either Enabled or Disabled. For Place, Share Farm, and Shadow Copy, this shows the volume-scan status. For Place and Share Farm, this also shows the current file-migration status.

If you use `show policy details`, the output shows the full details of every rule and share farm on the system. These details are described below, in the sections about rules, share farms, and volume-level filesets.

**Guidelines: Namespaces** The `show policy namespace` command shows only the rules and share farms in the given namespace. This output contains a **Namespace Migration Configuration** table, followed by tables of the namespace's rules.

The **Namespace Migration Configuration** table contains the following fields:

**Migrate-Attempts** is the number of times that a rule attempts to migrate a file before it declares a failed migration. You can change this with the `policy migrate-attempts` command.

**Migrate-Delay** is the number of seconds that a rule waits after a file has changed before the rule attempts to migrate the file. Changes often occur in batches, so this delay prevents repetitive migrations for a file that is being rewritten. You can use the `policy migrate-delay` command to reset this delay.

**Migrate-Retry-Delay** is the delay after a failed migration before the rule retries. The `policy migrate-retry-delay` command controls this setting.

Each volume has a separate table with all of its rules. These tables are similar to the one in the summary output, with the addition of the **Rule Priority** field. If two rules contradict for a given file, the higher-priority rule is enforced and the other rule is ignored. For example, if Rule 3 migrates a file to share A and Rule 6 migrates the same file to share B, Rule 3 is enforced and the file migrates to share A.

Rules are prioritized in groups as follows: shadow-copy rules (`shadow-copy-rule`) are the highest priority, followed by file-placement rules (`place-rule`) that only use a share or share farm as their source (`source`), followed by file-placement rules that use a source fileset (`from (gbl-ns-vol-plc)`), followed by share farms (`share-farm`) at the lowest priority. The only rules that can possibly contradict one another are the third group: file-placement rules that move a fileset (as opposed to draining a share). To change the order of these rules, you can use `policy order-rule`.

A “`drain_share_rule`” is created as the by-product of the `remove-share migrate` command. This is prioritized in the second group (file-placement rules that use a source share) while it is running. The policy engine demotes it to the third group (lower-priority file-placement rules) after the share is removed.

Within their categories, rules are prioritized in the order that they are created.

The `details` view shows the full details of every rule and share farm in this namespace.

**Guidelines: Volumes** The `show policy namespace ... volume` command focuses on the snapshot configuration, free space, share farms, and rules in a single volume. This is a series of summary tables unless you use the `details` flag.

---

**Guidelines: Volume  
Snapshot  
Configuration**

The show policy namespace ... volume command shows the volume-level configuration for snapshots. These settings are only relevant in a volume that has at least one snapshot rule configured. This section contains the following fields:

**Point-in-Time Consistency** is “Enabled” or “Disabled,” depending on whether or not the volume uses snapshot fencing. The VIP fence, if enabled, blocks all client access to the volume while the filers take their coordinated snapshots. Use the [snapshot consistency](#) command to allow or disallow this fence.

**Management Command Timeout** is the number of seconds that the volume software waits for any filer to respond to a command. If this time expires, the command times out. This is almost always 80 seconds.

**CIFS Directory Name** only appears if the volume supports CIFS. This is the pseudo directory that well-informed CIFS clients (administrators) can use to access their snapshots. You can use the [snapshot directory cifs-name](#) command to change this name.

**NFS Directory Name** only appears if the volume supports NFS. This is the pseudo directory that well-informed NFS clients (administrators) can use to access their snapshots. You can use the [snapshot directory nfs-name](#) command to change this name.

**Directory Display** is “All Exports” (clients see the ~snapshot/.snapshot directory in any front-end CIFS share or NFS export) or “Volume Root” (clients only see the directory only in a front-end share of the volume’s root directory), or “None.” You can use the [snapshot directory display](#) command to change this.

**Hidden File Attribute** only appears if the volume supports CIFS. This is “Yes” if the special ~snapshot directory has its “hidden” DOS attribute raised. Use an optional argument in the [snapshot directory display](#) command to control this setting. This has no effect on NFS clients.

**Restricted Access Configured** also only appears for a volume that supports CIFS. This is “Yes” if a Windows-Management Authorization (WMA) group restricts the CIFS clients that can access snapshots. Use the [snapshot privileged-access](#) command to control this setting. As above, this has no effect on NFS clients.

**VSS Mode** only appears for a volume that supports CIFS. This field indicates the client-machine versions for which the volume supports the Volume Shadowing Service (VSS). VSS is an intuitive interface that clients can use to access their snapshots. This is “Windows XP” (the volume supports VSS for Windows-XP and newer client machines), “Pre-Windows XP” (the volume also supports VSS for Windows-2000 clients), or “None.” Direct volumes do not support VSS. For managed volumes, use the [snapshot vss-mode](#) command to change this setting. This does not affect NFS clients.

**Guidelines: Share  
Free Space**

The `show policy namespace ... volume` command also shows the free-space thresholds and status from each of its shares. This is a table with the following columns:

**Share Name** identifies the share in the volume.

**Free Space Thresholds** shows the two thresholds that you can set with the `policy freespace` command:

- **Maintain** is the amount of free space to preserve on the share. The policy engine prevents any migrations from reducing the free space below this value.
- **Resume** is the amount of free space that is required on the share before it is eligible for migrations. The policy engine uses this value when the share has reached its **Maintain** value; it pauses all migrations to the share until the share's free space rises back up to this value.

**Free Space Status** displays the current state of free space on each share:

- **Free** is the current amount of free space,
- **Size** is the total size of the back-end share, and
- **Pct Free** is the percentage of free space remaining on the share.

**Guidelines: Share  
Farms**

A section for each share farm appears if you focus on the volume (`show policy namespace ... volume`) or focus on the share farm itself (`show policy namespace ... volume ... rule share-farm-name`). The output has a table of shares for a share farm, followed by a “New File Placement” rule for the share farm. The first table of shares has the following columns:

**Placement Frequency** shows the percentage of new files that the `balance` rule sends to this share. This also shows the numbers used to calculate that percentage.

**Freespace Status** shows the free space at the share.

The second section describes a “New File Placement” rule with the same name as the share farm. This is an implicit rule for every share farm. Its output is described below.

---

**Guidelines: New File Placement Rules and Place Rules**

A section for each file-placement rule appears if you focus on the volume (`show policy namespace ... volume`) or focus on the rule itself (`show policy namespace ... volume ... rule`). The output for file-placement rules and new-file-placement rules contains the following tables of settings and statistics:

**Configuration** shows all of the administrative settings for this rule or share farm.

**Status** displays the current status of volume scans and file migrations, which happen periodically. This also shows the status of new-file placement, which occurs as clients create new files.

**Cumulative Statistics** are the numbers of files migrated, migration failures, and migration retries since the share farm was created. This only appears if the rule or share farm is configured to perform migrations. You can use the `policy migrate-attempts`, `policy migrate-delay`, and `policy migrate-retry-delay` commands to control the migration-retry behavior. One field refers to “Inline Overflow” errors, which indicate that the placement rule received more inline-notification events (see `inline notify`) than it could record in its database; contact F5 Support if any such errors appear.

**Queue Statistics** counts the files where an initial attempt at migration failed (perhaps because the file was locked), so the file was placed into a queue for a later migration attempt.

**Last Scan Statistics** describes the last full scan of the volume. This does not appear until the first scan is complete.

**Current Scan Statistics** describes the current scan of the volume, which may not have started yet or may be currently running. This does not appear while the rule is idle.

**Guidelines: Snapshot Rules**

A section for each snapshot rule appears if you focus on the volume (`show policy namespace ... volume`) or focus on the rule itself (`show policy namespace ... volume ... rule`). Each section describes one [snapshot rule](#). The output contains the following tables:

**Configuration** shows all of the administrative settings for this snapshot rule.

**Archive Configuration** appears for a snapshot rule that is recording its volume’s configuration (and, typically, its metadata) in a [file-history archive](#). If the snapshot rule regularly records this data, you can query the archive later to find the back-end location of any file at any given time. This is useful for backups.

**Cumulative Statistics** shows the number of snapshots attempted, successful snapshot runs, failed runs, and the overall success rate. If the snapshot sends its data to a file-history archive, there are also statistics for metadata and volume configurations that were archived.

**Last Snapshot Statistics** describes the results of the rule’s most-recent snapshot. If the snapshot rule sends data to a file-history archive, this also includes archiving results.

**Snapshots** is a table of the rule’s currently-retained snapshots. These are the snapshots that are accessible to the volume’s clients. These snapshots are all managed by this snapshot rule, and do not include any snapshots invoked at the filer itself.

**Guidelines: Replica  
Snapshot Rules**

A section for each replica-snapshot rule appears if you focus on the volume (`show policy namespace ... volume`) or focus on the rule itself (`show policy namespace ... volume ... rule`). Each section describes one [snapshot replica-snap-rule](#). The output contains the following tables:

`Configuration` shows all of the administrative settings for this replica-snapshot rule.

`Cumulative Statistics`,

`Last Snapshot Statistics`, and

`Snapshots` are the same tables that also appear for standard snapshots. These are described above.

**Guidelines:  
Notification Rules**

A section for each notification rule appears if you focus on the volume (`show policy namespace ... volume`) or focus on the rule itself (`show policy namespace ... volume ... rule`). Each section describes one [notification rule](#), which takes regular snapshots to support the ARX API. The output contains the following tables:

`Configuration` shows all of the administrative settings for this notification rule.

`Cumulative Statistics`,

`Last Snapshot Statistics`, and

`Snapshots` are the same tables that also appear for standard snapshots. These are described above.

**Guidelines:  
Shadow-Copy Rules**

Each shadow-copy rule has a section in the detailed output, too. This contains the following tables:

`Configuration` shows all of the administrative settings for this shadow-copy rule.

`Status` shows the overall status of the most-recent shadow-copy run. A status of “Complete” indicates that the volume copied all files and directories successfully.

**Guidelines: Volume  
Filesets**

For each fileset in the volume, a single `Configuration` table shows all of the administratively-set parameters for the fileset. To see all filesets defined in `gbl` mode, use [show policy](#).

- Samples** `bstnA# show policy`  
shows all policy information. See [Figure 27.3 on page 27-43](#) for sample output.
- `prtlnA# show policy namespace nemed`  
on a different switch, shows policy information for the namespace named “nemed.” See [Figure 27.4 on page 27-44](#) for sample output.
- `prtlnA# show policy namespace nemed details`  
shows details for every rule and share farm in “nemed.” See [Figure 27.5 on page 27-44](#) for sample output.
- `prtlnA# show policy namespace nemed volume /acctShdw`  
shows policy information for the volume named “nemed~/acctShdw.” See [Figure 27.6 on page 27-45](#) for sample output.
- `bstnA# show policy namespace wwmed volume /acct rule docs2das8`  
shows the details for one rule. See [Figure 27.7 on page 27-45](#) for sample output.

## show policy files-closed

**Purpose** A file-placement rule can automatically close an open file and hold it closed until the rule finishes migrating the file. (This only applies to files opened by CIFS clients.) Use the `show policy files-closed` command to view all files that have been auto-closed by a particular volume.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show policy files-closed namespace namespace volume vol-path [rule rule-name]`

*namespace* (1-30 characters) is the CIFS-supporting namespace,

*vol-path* (1-1024 characters) identifies a managed volume by its path name, and

*rule-name* (optional, 1-1024 characters) is a particular file-placement rule. You can use `show policy namespace vol-path` for a list of all rules in a volume. If you omit this, the output shows the files closed by all file-placement rules in the volume.

**Guidelines** The `migrate close-file` command makes a file-placement rule close open files automatically. This command shows files that have been automatically closed by a rule, not files that are closed by CIFS clients.

The output shows the **Namespace** and **Volume** in its top two fields. The **Rule** field shows the name of the rule. If the rule is a file-placement rule, a table appears below it with one row for every auto-closed file. Each row shows the exact time the file was closed (in UTC, not local time) and the virtual path to the file. The virtual path starts at the root of the managed volume.

**Sample** `bstnA# show policy files-closed namespace medarcv volume /rcrds`  
shows all files that have been automatically closed by the “medarcv~/rcrds” rule. See [Figure 27.8](#) for sample output.

**Related Commands** [migrate close-file](#)  
[show policy](#)

## source

**Purpose** A file-placement rule moves files onto chosen storage. You can also use a file-placement rule to drain all files off of a share or shares. Use the `source` command to select a source share or a source share farm for a file-placement rule.

**Mode** `gbl-ns-vol-plc`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `source share share-name`  
`source share-farm share-farm-name`  
`no source`

*share-name* (1-64 characters) is the name of a source share in the current volume. This causes the placement rule to select its files from a single share.

*share-farm-name* (1-64 characters) is a share farm in the current volume. This causes the placement rule to select its files from the chosen share farm.

**Default(s)** `no source`

**Guidelines** This command restricts a file-placement rule to a particular source share or share farm. It is designed for draining all files from a share or share farm, usually to prepare for removing the share(s) from the volume. You can drain the shares, wait for all of the volume's [snapshot rules](#) to age out, and then use [remove-share migrate](#) to remove them.

This is *not* recommended for a volume with Tiered storage, where file-placement rules migrate new files to Tier-1 shares and older files to Tier-2 shares. Those file-placement rules should select their files from every share in the managed volume.

**Samples** The following example selects the “`archives~/etc~rh1`” as a source share:

```
bstnA(gbl-ns-vol[archives~/etc])# place-rule empty
bstnA(gbl-ns-vol-plc[archives~/etc~empty])# source share rh1
bstnA(gbl-ns-vol-plc[archives~/etc~empty])# ...
```

This example selects an entire share farm:

```
bstnA(gbl-ns-vol[insur~/claims])# place-rule drainFm
bstnA(gbl-ns-vol-plc[insur~/claims~drainFm])# source share-farm archival
bstnA(gbl-ns-vol-plc[insur~/claims~drainFm])# ...
```

**Related Commands** [place-rule](#)  
[snapshot rule](#)  
[remove-share migrate](#)

## tentative

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | You can set a file-placement rule to run simulations instead of actually migrating files. This can be useful for projecting the effects of a file-placement rule on your back-end filers. Use the <b>tentative</b> command to disable actual migrations in the current rule. Use <b>no tentative</b> to activate migrations in the current file-placement rule.                                                                 |
| <b>Mode</b>             | gbl-ns-vol-plc                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Syntax</b>           | <b>tentative</b><br><b>no tentative</b>                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default(s)</b>       | disabled                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Guidelines</b>       | A tentative rule logs its proposed migrations in the syslog without actually migrating any files. This allows you to see the results of the rule without actually committing to it. The log component, POLICY_ACTION, creates the syslog messages. Use the <a href="#">show logs syslog</a> (or <a href="#">grep logs pattern syslog</a> ) command to see the results that would have occurred had the rule been fully enabled. |
| <b>Samples</b>          | <pre>bstnA(gbl-ns-vol-plc[archives~/docs~2bkup])# tentative</pre> makes the current file-placement rule, “2bkup,” a tentative rule. The next time it runs, it does not perform any migrations.<br><br><pre>bstnA(gbl-ns-vol-plc[archives~/docs~2bkup])# no tentative</pre> takes the “2bkup” rule out of the tentative state. The next time the rule runs, it performs actual file migrations.                                  |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | By default, a file-placement rule finds its source files by monitoring all new files as they are created, monitoring client changes as they happen ( <i>inline</i> ), <i>and</i> scanning the volume for existing files. Use the <b>no volume-scan</b> command to disable volume scans and work with new and changed files only.<br><br>Use the <b>volume-scan</b> command to re-enable volume scans for the current rule. |
| <b>Mode</b>             | gbl-ns-vol-plc                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Security Level</b>   | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Syntax</b>           | <b>no volume-scan</b><br><b>volume-scan</b>                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Default(s)</b>       | <b>volume-scan</b>                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Guidelines</b>       | This can be useful for situations where shares already have current files distributed correctly. Note that these situations are somewhat rare. With volume scans disabled, all new and edited files are placed appropriately and no time is wasted examining back-end shares.<br><br>You can also stop the rule from receiving client-change notifications; use <b>no inline notify</b> command.                           |
| <b>Sample</b>           | <pre>bstnA(gbl-ns-vol-plc[wwmed~/acct~toNas23])# no volume-scan</pre> disables volume scans for the current rule on the '/acct' volume.                                                                                                                                                                                                                                                                                    |
| <b>Related Commands</b> | <a href="#">place-rule</a><br><a href="#">inline notify</a>                                                                                                                                                                                                                                                                                                                                                                |

## wait-for migration

**Purpose** Use the `wait-for migration` command to wait for a file-placement rule to finish migrating files from a source to a target.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, and operator

**Syntax** `wait-for migration namespace name volume vol-path rule rule [timeout timeout]`

*name* (1-30 characters) is the name of the namespace.

*vol-path* (1-1024 characters) identifies the volume.

*rule* (1-2096 characters) is the name of the rule that is migrating files (such as a place rule).

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - none, wait indefinitely

**Guidelines** A file-placement rule (created with the [place-rule](#) command) may take a long time to migrate a very-large fileset. You can use the `wait-for migration` command to wait for the operation to finish.

If you set a *timeout* and it expires before all files have finished migrating, the command exits with a warning. To interrupt the `wait-for migration` command, press `<Ctrl-C>`.

This can be useful for CLI scripts, which you can copy onto the switch (with [copy ftp](#), [copy scp](#), [copy {nfs/cifs}](#), or [copy tftp](#)), and [run](#).

**Sample** `bstnA# wait-for migration namespace medarcv volume /rcrds rule  
dailyArchive timeout 30`

waits up to 30 seconds for the “dailyArchive” rule to finish a file migration.

**Related Commands** [place-rule](#)

| <b>Guidelines</b>       | <p>The <code>auto-migrate</code> command allows the share farm to migrate files away from any of its shares who get too low on free space. The <code>policy freespace</code> command sets the minimum free space to maintain at a given share. The policy engine migrates files off of the share to other shares in the same share farm, until the share's free space reaches or exceeds the <code>resume-migrate</code> threshold you set with the same <code>policy freespace</code> command.</p> <p>This command migrates files that already exist in the share farm. To balance the distribution of newly-created files, use the <code>balance</code> command. This command only functions with <code>balance capacity</code>, which takes a share's free space into consideration when it distributes new files. This command cannot function in a share farm where <code>constrain-files</code> or <code>constrain-directories</code> are active; the constraints make auto migration impossible.</p> <p>The share farm cannot migrate a file that is open through CIFS and holding an exclusive-write lock. The <code>show cifs-service open-files</code> command shows all such files, and <code>close cifs file</code> closes one from the CLI.</p> <p>Use the <code>show statistics migration</code> command to monitor the file-migration activity in this share farm.</p> <p>If an automatic migration fails, the policy engine waits 300 seconds (five minutes) and retries the migration.</p> |
| <b>Sample</b>           | <pre>bstnA(gbl-ns-vol-sfarm[wwmed~/acct~fm1])# auto-migrate</pre> <p>starts auto migration away from any share in the "fm1" farm whose free space drops below the <code>policy freespace</code> setting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## balance

**Purpose** Use the **balance** command to balance all newly-created files amongst the shares in a share farm.

**Modes** gbl-ns-vol-sfarm

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **balance {capacity | latency | round-robin}**

**capacity** distributes files to each share based on the share's current free space (capacity). If share A has twice as much free space as share B, it gets twice as many new files.

**latency** places more files in shares with low latency than shares with higher latency. Share *latency* is the average round-trip time from the ARX to the share; low latency is a sign of more available bandwidth between the switch and the share.

**round-robin** uses manually-configured weights to guide the distribution. If share A has a weight that is twice as high as share B's weight, share A gets twice as many new files. You assign weight to a share when you add it to the share farm with [share \(gbl-ns-vol-sfarm\)](#).

**Default(s)** **balance round-robin**

**Guidelines** Any unavailable shares are removed from the new-file balancing rotation automatically. A share also drops out of the rotation if its free space drops too far; use the [policy freespace](#) command to set the minimum free space to maintain on a share.

To stop the distribution of new files, you can use [constrain-files](#) to constrain any new file to the same share as its parent directory. Additionally, you can use [constrain-directories](#) to keep directories with their parents. These **constrain** commands disable the effects of any **balance** command.

To activate balancing for the current share farm, use the [enable \(gbl-ns-vol-sfarm\)](#) command at the end of the command sequence. To stop balancing for the current share farm, use the **no** [enable \(gbl-ns-vol-sfarm\)](#) command, or invoke one of the **constrain** commands discussed above.

The [auto-migrate](#) command moves existing files off of a share if its free space drops too far. The **auto-migrate** command only functions if **balance capacity** is set, and you cannot set any other balance option if **auto-migrate** is enabled in this share farm.

**Samples**

```
bstnA(gbl-ns-vol-sfarm[wwmed~/acct~fm1])# balance capacity
```

  
balances new files for the 'acct~fml' share farm based on share capacity.

```
bstnA(gbl-ns-vol-sfarm[ns12~/usr~fm5])# share sh15 weight 40
bstnA(gbl-ns-vol-sfarm[ns12~/usr~fm5])# share sh16 weight 40
bstnA(gbl-ns-vol-sfarm[ns12~/usr~fm5])# balance round-robin
```

  
configures round-robin distribution in the "/usr~fm5" share farm. Two shares in the farm have equal weights, so the policy engine assigns them the same number of new files.

| <b>Purpose</b>                                                     | Use the <code>constrain-directories</code> command to keep any newly-created directory on the same share as its parent. That is, the share that holds the parent's master directory, for situations where the parent is striped on multiple shares in the volume.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                                                                    | <p><i>depth</i> (optional, integer 0-100) is the maximum depth of new directories that the share farm is allowed to <code>balance</code>. Below this directory depth, any new directory stays on the same share as its parent. This tends to preserve cohesive directory trees on back-end filers. For example, consider a volume that contains three directory trees, <code>/a</code>, <code>/b</code>, and <code>/c</code>: a share-farm with a depth of 1 could distribute the three directories to three separate shares, then keep the lower-level directories with their parents.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Default(s)</b>                                                  | <code>no constrain-directories</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Guidelines</b>                                                  | <p>This limits or entirely disables the <code>balance</code> rule, which balances the placement of new files.</p> <p>Use the <code>constrain-files</code> command to keep new files with their parent directories, too. If new files are not constrained and a client creates multiple files in the same directory, the <code>balance</code> rule is likely to distribute the files to multiple shares; to hold those files, it must replicate the directory in each share. This is called directory <i>striping</i>. In this situation, the <code>constrain-directories</code> command is choosing the share with the first (master) copy of the directory, but more copies are likely to exist.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Guidelines:<br/>Share-Farm Mirroring<br/>in a Tiered Volume</b> | <p>Many installations use <code>place-rules</code> and <code>age-filesets</code> to implement tiered storage in a managed volume. For example, files modified in the past quarter are placed onto tier 1, and files that have gone unmodified for more than a quarter migrate down to tier 2. The tiers can be individual shares or they can be share farms. If they are share farms where <code>constrain-files</code> or <code>constrain-directories</code> is active, the volume uses an algorithm called <i>share-farm mirroring</i> to determine which share in the destination share farm gets the migrated subdirectory.</p> <p>The share-farm mirroring technique finds a share for a directory when its parent's master directory is on another share farm. For example, suppose the master directory for <code>/home/jsmith</code> is on share farm A, the tier 1 share farm, but one of its subdirectories should migrate to share farm B. The mirroring technique finds the right share to receive the constrained subdirectory. The volume mirrors the share farms by mapping the first shares in each farm to each other, the second shares in each farm to each other, and so forth. If the master resides on share 2 in share farm A, all other share farms constrain their stripes to share 2. If <code>/home/jsmith</code> is on share 3 in the tier 1 share farm, the stripes for <code>/home/jsmith</code> reside on share 3 of the tier 2 farm and share 3 of the tier 3 farm. The constraints keep the directory on the same share in each farm, together with its constrained subdirectories.</p> <p>Share farm mirroring requires all tiers to be share farms; do not mix a tier 1 share with a tier 2 share farm. Also, the mirroring algorithm works best if all share farms have the same number of shares.</p> |

**Samples** `bstnA(gbl-ns-vol-sfarm[ns2~/usr~fm4])# constrain-directories`  
forces all new directories in the ns2~/usr~fm4 share farm to remain in their parent directories in the share farm.

`bstnA(gbl-ns-vol-sfarm[ns2~/usr~fm4])# constrain-directories below 1`  
forces all new directories in the ns2~/usr~fm4 share farm to be constrained to their parent directories when the new directories are below the first subdirectory level.

**Related Commands** [namespace](#) -> [volume](#) -> [share-farm](#)  
[balance](#)  
[constrain-files](#)

## constrain-files

**Purpose** Use the `constrain files` command to specify that new files be placed in the same shares as their parent directories. This reduces directory striping in the share farm; the share that has the master directory is typically the only share with any instance of the directory at all.

Use the `no` form of the command to remove the restriction and allow the `balance` rule to distribute files evenly throughout the current share farm.

**Modes** `gbl-ns-vol-sfarm`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `constrain-files`  
`no constrain-files`

**Default(s)** `no constrain-files`

**Guidelines** This command enables you to restrict new-file placement to the same share as the parent directory. It disables the `balance` command with respect to files. This has no effect on the auto-migration of existing files, which is done to relieve a share that is running low on free space (see [auto-migrate](#)). Note that an auto migration has the side effect of creating stripe directories on other shares, but only when free space is running low.

You can also use the `constrain-directories` command to keep directories on the same share as their parents.

**Guidelines:  
Share-Farm Mirroring  
in a Tiered Volume**

Many installations use `place-rules` and `age-filesets` to implement tiered storage in a managed volume. For example, files modified in the past week are placed onto tier 1, files modified last week are on tier 2, and files that have not been modified any time in the past 2 weeks are placed on tier 3. The tiers can be individual shares or they can be share farms. If they are share farms where `constrain-files` or `constrain-directories` is active, the volume uses an algorithm called *share-farm mirroring* to determine which share gets a file.

The share-farm mirroring technique finds a share for a file when its parent's master directory is on another share farm. For example, suppose the master directory for `/home/jdoe` is on share farm A, the tier 1 share farm, but one of its files should migrate to share farm B. The mirroring technique finds the right share to receive the constrained file. The volume mirrors the share farms by mapping the first shares in each farm to each other, the second shares in each farm to each other, and so forth. If the master resides on share 4 in share farm A, all other share farms constrain their stripes to share 4. If `/home/jdoe` is on share 2 in the tier 1 share farm, the stripes for `/home/jdoe` reside on share 2 of the tier 2 farm and share 2 of the tier 3 farm. The constraints keep the directory on the same share in each farm, together with its constrained files.

Share farm mirroring requires all tiers to be share farms; do not make a stand-alone share into tier 1 and a share farm into tier 2. Also, we recommend that all share farms have the same number of shares.

**Sample** `bstnA(gbl-ns-vol-sfarm[ns~/vol~fm])# constrain-files`  
causes all new files in the `"ns~/vol~fm"` share farm to remain in the same shares as their parent directories.

**Related Commands** [namespace](#) -> [volume](#) -> [share-farm](#)  
[balance](#)  
[constrain-directories](#)

## enable (gbl-ns-vol-sfarm)

**Purpose** Use the `enable` command to enable the current rule. A new rule is disabled by default, and the policy engine ignores disabled rules.

Use `no enable` to disable the current rule.

**Modes** `gbl-ns-vol-sfarm`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `enable`  
`no enable`

**Default(s)** `no enable`

**Guidelines** You must enable a share farm for the policy engine to enforce any of its policies (such as those set with `balance` or `auto-migrate`).

**Sample** `bstnA(gbl-ns-vol-sfarm[archives~/multimedia~minSpace])# no enable`  
disables all rules in the “minSpace” share farm.

**Related Commands** `namespace` -> `volume` -> `share-farm`  
`auto-migrate`  
`balance`

---

## policy freespace (gbl-ns-vol-sfarm)

**Purpose** Whenever any rule migrates a file to a share, it checks the share's free space against two thresholds. Each share has a minimum free space to *maintain*, as well as another (typically larger) level of free space called a *resume* threshold. If the file would reduce the share's free space below the *maintain* level, the rule waits until the free space rises to the *resume* level before migrating any more files to the share. The [policy freespace](#) command sets these free-space thresholds for an ARX share. Use this [policy freespace](#) command, from gbl-ns-vol-sfarm mode, to set the same thresholds for every share in the current share farm.

Use `no policy freespace` to return to the defaults for every share in the current share farm.

**Mode** gbl-ns-vol-sfarm

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `policy freespace maintain{k|M|G|T} resume-migrate resume{k|M|G|T}`

`policy freespace percent maintain-pct resume-migrate resume-pct`

`no policy freespace`

*maintain* is the amount of free space to maintain on these shares.

**k|M|G|T** chooses the unit of measure: **k**ilobytes, **M**egabytes, **G**igabytes, or **T**erabytes. A kilobyte is 1,024 bytes, a megabyte is 1,024 kilobytes (1,048,576 bytes), and so on..

*resume* is a free-space level for resuming migrations to any of these shares. The policy engine uses this value if one of the shares has reached its *maintain* value; no rule can migrate to such a share until its free space rises back to the *resume* level.

**percent** (optional) indicates that you are using disk-space percentages for these values instead of specific size measures.

*maintain-pct* (1-100) expresses the *maintain* value as a percentage of the overall share size.

*resume-pct* (1-100) is the *resume* threshold, expressed as a percentage of the share's total space.

**Default(s)** *maintain* - 1G

*resume* - 2G

**Guidelines** This is a macro command for the [policy freespace](#) command in gbl-ns-vol-sfarm mode. This command invokes the individual [policy freespace](#) command for every share in the current share farm. The output from [show global-config](#) shows the individual share-level [policy freespace](#) commands, not this macro command.

This is similar to the [policy freespace \(gbl-ns, gbl-ns-vol\)](#) command, a macro command for namespaces and volumes.

**Samples** `bstnA(gbl-ns-vol-sfarm[wwmed~/acct~fm1])# policy freespace 3G  
resume-migrate 4G`

makes the policy engine maintain at least 3 Gigabytes of free space on every share in the “fm1” share farm. If that limit is reached by clients or approached by a migration rule on any of these shares, the share is ineligible for any more migrations until its free space rises back up to 4 Gigabytes.

`bstnA(gbl-ns-vol-sfarm[wwmed~/acct~fm1])# no policy freespace`

reverts all shares in the above share farm to the default free-space thresholds.

**Related Commands** [namespace](#) -> [volume](#) -> [share-farm](#)  
[policy freespace](#)  
[policy freespace \(gbl-ns, gbl-ns-vol\)](#)  
[place-rule](#)  
[show policy](#)

---

## share (gbl-ns-vol-sfarm)

**Purpose** Use the `share` command from `gbl-ns-vol-sfarm` mode to add a managed volume share to the current share farm.

Use the `no` form of the command to delete a share from the share farm.

**Mode** `gbl-ns-vol-sfarm`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `share name [weight weight]`  
`no share name`

*name* (1-64 characters) is the name of a share in the current managed volume. Use the `show global-config namespace` command for a list of configured shares.

*weight* (0 - 100) is the new-file-placement weight for the share. This number is proportional to other shares in the share farm; if one share has a 60 weight and another share has 30, the first share gets twice as many new files as the second. This weight is used with the `balance` round-robin rule; it is ignored for any other `balance` setting.

**Default(s)** None.

**Guidelines** You can add as many shares as desired. A share can only belong to one share farm.

The `no share` command from `gbl-ns-vol-sfarm` mode does not delete the share's configuration; it only deletes the share from the share farm.

The order in which you invoke this command determines the ID of the share within the share farm. The first-added share has an ID of 1, the second has an ID of 2, and so forth. The share IDs are used for *share-farm mirroring* in a tiered volume; if a file migrates to a tier 3 share farm, its parent's master directory is in the tier 1 share farm, and it is constrained to the same share as its parent's master directory, the file goes to the share with the same ID as the parent's master directory. The documentation for `constrain-files` and `constrain-directories` provides further details on share-farm mirroring.

If you remove the last share from the share farm with `no share`, other rules (such as a `place-rule`) can no longer use the share farm as a target for file migrations. The CLI prompts for confirmation if you attempt to remove the last share from the farm; enter `yes` to proceed.

**Samples** `bstnA(gbl-ns-vol-sfarm[archives~/multimedia~gold])# share lun77`  
 adds the `lun77` share to the gold share farm.

`bstnA(gbl-ns-vol-sfarm[archives~/multimedia~gold])# no share lun70`  
 deletes the `lun70` share from the "gold" share farm.

**Related Commands** `namespace` -> `volume` -> `share-farm`  
`show global-config namespace`  
`constrain-files`  
`constrain-directories`

## share-farm

**Purpose** A share farm is a group of shares in a managed volume. You can balance the new files that are created in a share farm, and you can auto-migrate files off of a share that is low on free space. Use the `share-farm` command to create a new share farm, or to edit an existing one.

Use the `no` form of the command to delete a share farm.

**Mode** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `share-farm name`  
`no share-farm name`

*name* (1-1024 characters) is the name you choose for the share farm.

**Default(s)** None

**Guidelines** When you create a new share farm, the CLI prompts for confirmation. Enter `yes` to create the share farm. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.)

This places you in `gbl-ns-vol-sfarm` mode, where you must use the [share \(gbl-ns-vol-sfarm\)](#) command to add at least one share to the farm. You can optionally use [auto-migrate](#) to migrate files off of any share that falls below a minimum amount of free space. The [balance](#) command distributes new files amongst the shares in the farm; you can weight this distribution based on current free space at each share (shares with more space get more new files), current latency at each share (shares with more bandwidth get more new files), or according to the weights you set with the [share \(gbl-ns-vol-sfarm\)](#) command. The latter form of the [balance](#) rule is active by default. To stop balancing new files, use the [constrain-files](#) and/or [constrain-directories](#) commands to keep any new file and/or directory on the same share as its parent directory.

Use [show policy](#) for details about a share farm and its policies. Use the [show statistics migration](#) command to monitor all migrations in the share farm.

Deleting a share farm has no effect on the farm's shares, other than to invalidate any of the share farm's policies.

**Samples** `bstnA(gbl-ns-vol[archives~/multimedia])# share-farm gold`

This will create a new share farm.

```
Create share farm 'gold'? [yes/no] yes
bstnA(gbl-ns-vol-sfarm[archives~/multimedia~gold])#
 creates a share farm named "gold" in the current volume.
```

```
bstnA(gbl-ns-vol[archives~/multimedia])# no share-farm platinum
 deletes the "platinum" farm.
```

Shadow Volume

---

# bandwidth-limit

**Purpose** You can use the `bandwidth-limit` command to set a bandwidth ceiling for the current shadow-copy rule. Each run of the rule abides by this limit.  
Use `no bandwidth-limit` to remove any limit on bandwidth.

**Modes** `gbl-ns-vol-shdwcp`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `bandwidth-limit rate[K|M|G|T]`  
`no bandwidth-limit`

*rate* (100,000-4,000,000,000,000, or 1M-4T) is maximum bandwidth that you choose for the current shadow-copy rule.

**K|M|G|T** (optional) chooses the units. These are Kbps, Mbps, Gbps, or Tbps. They are 10-based: 1 Kbps is 1,000 bps, 1 Mbps is 1,000,000 bps, and so forth. Do not include any space between the *rate* and this unit: **100G** is correct, but **100 G** is not. If you omit this, the units are bits-per-second (bps).

**Default(s)** `no bandwidth-limit`

**Guidelines** Each run of the current shadow-copy rule abides by this bandwidth limit.

**Sample** `bstnA(gbl-ns-vol-shdwcp[wmed~/acct~SVrule])# bandwidth-limit 750000`  
allows the 'SVrule' rule to use up to 750,000 BPS for its file transfers.

**Related Commands** [shadow-copy-rule](#)

## cifs-8dot3-resolution

**Purpose** File systems that support CIFS also support an *alternate name* for its files and directories. A file or directory whose name does not fit the old-style “8.3” pattern gets an alternate name from its back-end filer. If a file on the source volume has a primary name that matches another file’s alternate name, the shadow-copy rule cannot copy the file to the target volume. To enable the rule to safely perform this copy operation, use the `cifs-8dot3-resolution` command.

Use `no cifs-8dot3-resolution` to return to the default; this is not recommended.

**Modes** `gbl-ns-vol-shdwc`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `cifs-8dot3-resolution`  
`no cifs-8dot3-resolution`

**Default(s)** `no cifs-8dot3-resolution`

**Guidelines** The `no` form of this command implies that it is impossible for a client to create an 8.3 name that matches the alternate name of a different file. While this event is rare, it is possible at any site that supports CIFS. We recommend enabling this feature for all shadow-copy rules in all CIFS-supporting volumes.

**Sample** `bstnA(gbl-ns-vol-shdwc[insur~/claims~insurSV])# cifs-8dot3-resolution`  
sets the ‘insurSV’ rule to support copies of 8.3 names.

| <b>Syntax</b>           | <code>database-location volume</code><br><code>database-location metadata-share</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default(s)</b>       | <code>database-location metadata-share</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>       | <p>You must rebuild the shadow volume (with <code>nsck ... rebuild</code>) before you can use the <code>database-location volume</code> command. This is not required for moving the database to the recommended metadata share.</p> <p>If the shadow-copy rule runs out of disk space for its database, the database may be corrupted or the rule could hang indefinitely. A corrupted database causes a full scan of the source volume. The re-scan occurs on the next run of the rule, and it is time-consuming if the source volume is large. We recommend storing this on the metadata share for the volume. The volume's storage shares can expand unpredictably, according to the changing habits of the source volume's clients, and may unexpectedly run low on space. Volume metadata is generally smaller and grows at a regular pace. Furthermore, the ARX carefully monitors the disk space on a metadata share, issuing SNMP traps whenever space runs low.</p> |
| <b>Sample</b>           | <pre>bstnA(gbl-ns-vol-shdwcp[wmed~/acct~SVrule])# database-location metadata-share</pre> <p>places the shadow-copy database for "SVrule" onto its target volume's metadata share.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Related Commands</b> | <a href="#">shadow-copy-rule</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## delta-threshold

**Purpose** When a source file changes, a shadow-copy rule transfers only the file's changed portion (delta) to the shadow volume. Files that are considered "too small" are transferred in their entirety. Use `delta-threshold` to set the minimum file size to trigger a delta transfer, so that a file is always copied whole if it is smaller than the threshold.

Use `no delta-threshold` to revert to the default delta threshold.

**Modes** `gbl-ns-vol-shdwcp`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `delta-threshold file-size[k|M|G|T]`  
`no delta-threshold`

*file-size* (1-18,446,744,073,709,551,615) is the minimum size of a file that is eligible for delta transfers.

**k|M|G|T** (optional) specifies units; **k** for KiloBytes (1024 bytes), **M** for MegaBytes (1024\*1024 bytes), **G** for GigaBytes (1024\*1024\*1024), and **T** for TeraBytes (1024\*1024\*1024\*1024). Do not put any space between the number and this unit (for example, **100k** is valid but **100 k** is not). The default is bytes.

**Default(s)** `100M`

**Guidelines** A delta-transfer uses lower bandwidth than a full transfer, but requires more computation time on both the source volume and the shadow volume. This threshold saves the computation time for small files, which would not require a great deal of bandwidth if the rule always transfers the whole file. This is intended for networks with higher bandwidth, or for installations where the source and shadow volumes are on the same switch.

**Samples** `bstnA(gbl-ns-vol-shdwcp[wwmed~/acct~SVrule])# delta-transfer 1G`  
allows delta transfers only for files larger than 1 GigaByte.

`bstnA(gbl-ns-vol-shdwcp[archives~/etc~shdw])# no delta-transfer`  
returns to the default threshold.

## enable (gbl-ns-vol-shdwcp)

|                         |                                                                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>enable</code> command to enable the current shadow-copy rule.<br>Use <code>no enable</code> to disable the rule.                                                                                   |
| <b>Modes</b>            | <code>gbl-ns-vol-shdwcp</code>                                                                                                                                                                                   |
| <b>Security Role(s)</b> | <code>storage-engineer</code> or <code>crypto-officer</code>                                                                                                                                                     |
| <b>Syntax</b>           | <code>enable</code><br><code>no enable</code>                                                                                                                                                                    |
| <b>Default(s)</b>       | <code>no enable</code>                                                                                                                                                                                           |
| <b>Guidelines</b>       | You must enable the shadow-copy rule for the policy engine to use it. Once enabled, the shadow-copy rule follows its assigned schedule and copies its fileset from the source volume to the shadow volume.       |
| <b>Samples</b>          | <code>bstnA(gbl-ns-vol-shdwcp[archives~/etc~shdw])# enable</code><br>enables the “shdw” rule.<br><br><code>prt1ndA(gbl-ns-vol-shdwcp[nemed~/acct~SV2])# no enable</code><br>disables the “SV2” shadow-copy rule. |
| <b>Related Commands</b> | <a href="#">shadow-copy-rule</a>                                                                                                                                                                                 |

## from fileset (gbl-ns-vol-shdwcp)

**Purpose** Use the `from fileset` command to select the source fileset for the current shadow-copy rule. The shadow-copy rule periodically copies the fileset from the source volume to the shadow volume.

**Mode** `gbl-ns-vol-shdwcp`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `from fileset fileset-name [match {files | all}]`

*fileset-name* (1-1024 characters) identifies the fileset.

`match {files | all}` (optional) determines whether the fileset matches files only or files and directories.

**Default(s)** `match - files` only (and the directories that contain the matching files)

**Guidelines** You can use a single fileset as your source. All files in this fileset will be copied to the shadow volume, which you configure with the [target \(gbl-ns-vol-shdwcp\)](#) command.

If a single fileset is too restrictive, use the [union-fileset](#) command to join multiple filesets into one.

The [policy-cifs-attributes-fileset](#) is not compatible with shadow-copy rules. This command returns an error if you use a [policy-cifs-attributes-fileset](#) or a container fileset that includes one. (Container filesets are [intersection-filesets](#) and [union-filesets](#)).

**Sample** The following example selects the “worthSaving” source fileset for the shadow-copy rule, “SVrule:”

```
pvtIhdA(gbl-ns-vol-shdwcp[wmed~/acct~SVrule])# from fileset worthSaving
```

**Related Commands** [shadow-copy-rule](#)

# inline-notify

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | A shadow-copy rule keeps track of all source-volume directories where at least one change occurred. Each time the shadow-copy rule runs, it only examines and copies from the set of changed directories. Use <b>no inline-notify</b> to stop tracking source-volume changes, thus forcing a full tree-walk of the source volume for every shadow-copy run.<br><br>Use the <b>inline-notify</b> command track all source-volume changes. |
| <b>Modes</b>            | gbl-ns-vol-shdwcp                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Syntax</b>           | <b>no inline-notify</b><br><b>inline-notify</b>                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default(s)</b>       | <b>inline-notify</b>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>       | The default improves performance by keeping track of changed directories since the previous shadow copy. The policy engine performs a tree-walk (a complete scan) of the directories that changed, not wasting any cycles on directories that remained the same. You should only turn off inline notifications on advice from F5 Support.                                                                                                |
| <b>Sample</b>           | <pre>bstnA(gbl-ns-vol-shdwcp[ns3~/vol~betaSV])# <b>no inline-notify</b></pre> <p>disables inline notification for “betaSV.”</p>                                                                                                                                                                                                                                                                                                          |
| <b>Related Commands</b> | <a href="#">shadow-copy-rule</a>                                                                                                                                                                                                                                                                                                                                                                                                         |

## prune-target

**Purpose** By default, the first run of a shadow-copy rule ends by pruning all extraneous files and directories from the shadow volume. These are files and/or directories that were imported into the shadow volume but that have no counterparts in the source volume. The rule prunes these files and directories to ensure that the source and shadow are identical from the start. If the two volumes are already known to be identical, you can use `no prune-target` to avoid the unnecessary pruning phase.

Use the `prune-target` command to enable initial target pruning on the shadow (target) volume.

**Modes** `gbl-ns-vol-shdwcp`

**Security Level** `storage-engineer` or `crypto-officer`

**Syntax** `no prune-target`  
`prune-target`

**Default(s)** `prune-target`

**Guidelines** The `prune-target` command allows enabling or disabling of initial pruning on the target volume.

Even if the source and target volumes are identical, millions of files can consume time as the rule compares the two directory trees. The `no` form of this command is useful when performance is an issue.

This command has no effect on the rule's ability to synchronize deletions. If a client deletes a file or directory on the source volume, the shadow-copy rule always deletes its counterpart on the shadow volume. This command only affects files and directories that are unique to the shadow volume.

**Sample** `bstnA(gbl-ns-vol-shdwcp[wwmed~/acct~SVrule])# no prune-target`  
disables pruning of shadow volume target volumes for the 'SVrule' rule.

**Related Commands** [shadow-copy-rule](#)

---

# publish

**Purpose** A shadow-copy rule copies each file individually, publishing the file in the client-visible directory tree immediately after a successful transfer to a staging area. Some applications require all files to successfully transfer as a group. Use **publish group** to publish all of the files as a single group, after all files transfer without errors. Use **publish individual**, to return to the default: publish each file after a successful transfer.

**Modes** gbl-ns-vol-shdwcp

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **publish {group | individual}**

**group | individual** is a required choice:

**group** publishes all files as a group, after they have all successfully transferred to the shadow volume's staging area.

**individual** publishes each file individually, as it is transferred.

**Default(s)** **publish individual**

**Guidelines** The group publishing phase is designed for applications that require all shadow files to be present and consistent, such as a CAD project. If any part of the file-transfer fails, none of the changed files are published.

The **publish individual** method is intended for shadow volumes where file consistency is less important. For example, an installation with /home directories may prefer to have all the latest files as soon as possible, not allowing one failed transfer to prevent the publication of thousands of other files.

Some CIFS applications block all access to a file when the file is open, making it impossible for the shadow volume to copy the file. To prevent open CIFS files from stopping the entire transfer, use **publish individual**.

**Samples** `bstnA(gbl-ns-vol-shdwcp[wmed~/acct~SVrule])# publish group`  
reinstates the group-publishing phase for "SVrule."

`prtIndA(gbl-ns-vol-shdwcp[nemed~/acct~SV2])# publish individual`  
removes the group-publishing phase; each file is published directly after a successful transfer.

**Related Commands** [shadow-copy-rule](#)

## report (gbl-ns-vol-shdwcp)

**Purpose** Use this command to enable progress reports for the current shadow-copy rule.  
Use `no report` to prevent progress reports.

**Mode** `gbl-ns-vol-shdwcp`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `report file-prefix [verbose] [list-identical] [delete-empty]`  
`no report`

*file-prefix* (1-1024 characters) sets a prefix for all shadow-copy reports. Each report has a unique name in the following format:

*prefixYearMonthDayHourMinute.rpt*

For example, `home_backup200403031200.rpt` could be the name for one report with the “home\_backup” prefix.

**verbose** (optional) enables verbose data in the reports.

**list-identical** (optional) includes all files that are identical on both the source and shadow volumes. These files are not copied, so they are unlisted by default.

**delete-empty** (optional) causes the rule to delete any reports that contain no data. Empty reports are created when the source fileset did not change since the previous shadow copy.

**Default(s)** `no report`

**Guidelines** Every time the shadow-copy rule fires and duplicates the source fileset, the rule can generate a report to show the details of the copy session. The reporting feature is disabled by default; we recommend that you enable reporting for all shadow-copy rules, to keep a log of all shadow-copy sessions.

Use [show reports](#) for a list of reports, or `show reports file-name` to show the contents of one report.

**Samples** `prt1ndA(gbl-ns-vol-shdwcp[wwmed~/acct~SVrule])# report SVetc`  
enables reports for the shadow-copy rule, “SVrule.” For a sample report, see [Figure 29.1](#).

`bstnA(gbl-ns-vol-shdwcp[archives~/etc~shdw])# report etc verbose list-identical`  
enables verbose reports for the shadow-copy rule, “shdw.” The reports also include any files that were found to be identical on both the source and shadow volumes.

`bstnA(gbl-ns-vol-shdwcp[ns3~/usr~cdn])# no report`  
disables reports for the “cdn” rule.

## retry attempts

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | If a shadow-copy rule fails to transfer any files to the shadow volume, the rule makes multiple attempts to transfer the failed files. This retry mechanism can help a shadow-copy operation to succeed during a transient network failure, or during a failover at the target-volume site. Use the <code>retry attempts</code> command to set the retry limit for this rule.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Modes</b>            | <code>gbl-ns-vol-shdwcp</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Syntax</b>           | <code>retry attempts <i>count</i></code><br><br><i>count</i> (0-2,147,483,647) is the total number of retries for a failed shadow copy before waiting for the next rule run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default(s)</b>       | 5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Guidelines</b>       | <p>The shadow-copy rule keeps a list of all directories with failed files as it runs. After the run is complete, the rule checks the list and retries any directories that are in it. The rule repeats this process as often as you dictate with this command. If there are still failed transfers after the final retry attempt, the rule declares the run a failure.</p> <p>The <a href="#">retry delay</a> command sets the delay between these retry attempts. You can use these commands to compensate for transient network issues between your source and target sites.</p> <p>Each retry attempt creates a separate shadow-copy report. The report shows the results of the retry operation. (Use the <a href="#">report (gbl-ns-vol-shdwcp)</a> command to make the shadow-copy rule generate reports.)</p> |
| <b>Sample</b>           | <pre>bstnA(gbl-ns-vol-shdwcp[insur~/claims~insurSV])# <b>retry attempts 10</b></pre> <p>sets the shadow-copy rule, "SVrule," to retry up to 10 times if it encounters any file-transfer failures.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## retry delay

|                         |                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | When a shadow-copy run fails to transfer one or more of its files, the rule pauses for a period of time before retrying the failed file(s). You can use the <code>retry delay</code> command to set the length of this pause.                                               |
| <b>Modes</b>            | <code>gbl-ns-vol-shdwcp</code>                                                                                                                                                                                                                                              |
| <b>Security Role(s)</b> | <code>storage-engineer</code> or <code>crypto-officer</code>                                                                                                                                                                                                                |
| <b>Syntax</b>           | <code>retry delay <i>seconds</i></code><br><br><i>seconds</i> (60-7200) is the number of seconds between retries.                                                                                                                                                           |
| <b>Default(s)</b>       | 300 (seconds)                                                                                                                                                                                                                                                               |
| <b>Guidelines</b>       | The <code>retry attempts</code> command sets the number of retry attempts. Use these commands to compensate for transient network issues between your source and target sites.<br>After the connection is re-established, the rule resumes at the last-completed directory. |
| <b>Sample</b>           | <code>bstnA(gbl-ns-vol-shdwcp[insur~/claims~insurSV])# retry delay 120</code><br>causes the shadow-copy rule, "insurSV," to pause for two minutes (120 seconds) between each retry attempt.                                                                                 |
| <b>Related Commands</b> | <code>shadow-copy-rule</code><br><code>retry attempts</code>                                                                                                                                                                                                                |

## schedule (gbl-ns-vol-shdwcp)

**Purpose** Use this `schedule` command to assign a schedule to the current shadow-copy rule.  
Use `no schedule` to remove the rule's schedule.

**Mode** gbl-ns-vol-shdwcp

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `schedule name`  
`no schedule`

*name* (1-64 characters) identifies the schedule. Use `show schedule` for a list of configured schedules.

**Default(s)** None.

**Guidelines** A shadow-copy rule copies its fileset from the source volume to the shadow volume; each shadow-copy session occurs on a schedule. This command determines which schedule to use.

To create a schedule, use the gbl-mode `schedule` command.

You cannot use a schedule with a fixed `duration`; a shadow-copy rule must always run to completion in order to succeed.

**Sample** `prt1ndA(gbl-ns-vol-shdwcp[wmed~/acct~SVrule])# schedule hourly`  
assigns the "hourly" schedule to the shadow-copy rule, "SVrule."

**Related Commands** `shadow-copy-rule`  
`schedule`  
`show schedule`

# shadow

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <b>shadow</b> command to transform a standard volume into a read-only shadow volume. A <i>shadow volume</i> is a target for a shadow-copy.<br><br>Use <b>no shadow</b> to make the volume ineligible as a shadow-copy target, and to make it writable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Mode</b>             | gbl-ns-vol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Security Role(s)</b> | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Syntax</b>           | <b>shadow</b><br><b>no shadow</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default(s)</b>       | <b>no shadow</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Guidelines</b>       | <p>The volume must be disabled (no <a href="#">enable (gbl-ns, gbl-ns-vol)</a>) before you can use either <b>shadow</b> or <b>no shadow</b>.</p> <p>A Shadow volume is typically created on a different switch from its source volume(s). To add a volume at a different switch, log into the CLI at that switch and add the volume from there.</p> <p>A shadow volume does not keep its imported files; it uses its shares as repositories for the shadowed fileset(s). Therefore, the shadow volume deletes all extraneous files on its shares as soon as the shadow-copy rule first runs. The CLI prompts for confirmation before allowing this; to create the shadow volume, answer <b>yes</b> at the prompt.</p> <p>The <b>no shadow</b> command issues a similar warning, indicating that shadow copies in progress are aborted if you continue. This means removal of some interim files and databases, possibly affecting the shadow volume. The source volume is unaffected. Again, answer <b>yes</b> to continue.</p> <p>Clients can only have read access to the shadow volume. (Writes would corrupt the shadow copy.)</p> |

**Guidelines:** A volume cannot be used as a shadow volume if it contains any imported NetApp share with multiple qtrees. This is not an issue if each NetApp share is a single qtree, or if none of the NetApp shares contain any qtrees.

**Configuration Rules** The [shadow-copy-rule](#) must write to the volume's metadata when it copies files; use [modify](#) to allow this.

Choose a shadow volume with at least as much disk capacity as its source volume(s), or some shadow-copy operations may fail.

A [direct](#) volume (also known as a presentation volume) cannot be used as a shadow volume.

CIFS subshares are not supported on the filers behind a shadow volume. Some filers do not allow the shadow-copy rule to delete a directory under a subshare, and this is necessary if the same directory was deleted at the source volume. For more information on CIFS subshares and how a managed volume supports them, see the documentation for the [filer-subshares](#) command.

A shadow volume must support all of the protocols for its source volume(s). For example, an NFSv3 and CIFS volume can be a shadow for another volume with both of those protocols, or for a CIFS-only volume, or for an NFSv3 volume. It cannot be the target for an NFSv2 volume.

**Samples** `prtlndA(gbl-ns-vol[archives~/cdn])# shadow`

This will cause all the shares in the volume to be erased.

Are you sure you want to remove all data? [yes/no] **yes**  
changes the "/cdn" volume into a shadow volume.

```
prtlndA(gbl-ns-vol[nemed~/testvol])# no enable
prtlndA(gbl-ns-vol[nemed~/testvol])# no shadow
```

This will cause any un-published files and shadow databases to be erased.

Are you sure you want to proceed? [yes/no] **yes**  
reverts the "/testvol" volume back to a managed volume.

**Related Commands** [namespace](#) -> [volume](#)  
[no enable](#) (gbl-ns, gbl-ns-vol)  
[modify](#)

---

# shadow-copy-rule

**Purpose** Use the `shadow-copy-rule` command to instantiate a shadow-copy rule in the current volume. A *shadow-copy rule* regularly copies a fileset from the current volume to a read-only *shadow volume*.

Use the `no` form of the command to delete the rule.

**Modes** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `shadow-copy-rule name`  
`no shadow-copy-rule name`

*name* (1-1024 characters) is the name you choose for the rule.

**Default(s)** `None`

**Guidelines** When you first create a shadow-copy rule, a prompt asks for confirmation; enter **yes** to continue.

This command puts you into `gbl-ns-vol-shdwcp` mode, where you have various configuration commands for configuring the shadow-copy rule. Use the [from fileset \(gbl-ns-vol-shdwcp\)](#) command to select a fileset to copy. Use the [target \(gbl-ns-vol-shdwcp\)](#) command to choose a shadow volume as a destination for the file copies. The shadow volume must reside in the current RON; use [show ron](#) for a list of ARXes in the current RON. The [schedule \(gbl-ns-vol-shdwcp\)](#) command determines the schedule for making the shadow copies. Use the [enable \(gbl-ns-vol-shdwcp\)](#) command to start the rule.

If there are any network disconnects during a rule run, the rule pauses and retries to establish the connection. You can use the [retry attempts](#) and [retry delay](#) commands to manipulate the number of attempts and the length of time between them.

If a CIFS client has a file open on the source volume, the client must have opened the file with “shared read” access for the file to be shadow copied. Otherwise, the shadow copy fails for the current run of the rule. No application (including the shadow-copy rule) can open a file that is already opened, unless the first application opened with “shared read” access.

A volume cannot support a shadow-copy rule if it contains any imported NetApp share with multiple qtrees. This is not an issue if each NetApp share is a single qtree, or if none of the NetApp shares contain any qtrees.

**Guidelines: CIFS  
Options (Local  
Groups and “8.3”  
Names)**

If the filers behind the source volume use any Windows Local Groups or Local users, you may want to translate CIFS Security IDs (SIDs) between the source and shadow volumes. The [sid-translation \(gbl-ns-vol-shdwcp\)](#) command tells the rule to translate SIDs. This only applies to source/shadow volumes that support CIFS.

File systems that support CIFS also support an *alternate name* for any file or directory with a long file or directory name. The alternate-name support is for older Windows applications that only support “8.3” names. An 8.3 name is one with up to 8 characters and an optional extension with up to 3 characters. If a source-volume file has a primary name that matches a target-volume file’s alternate name, the source-volume file could overwrite the target-volume file. This causes the shadow copy to fail for the given file or directory, unless you set [cifs-8dot3-resolution](#) for this rule. This is a recommended setting.

**Guidelines: Options**

The `gbl-ns-vol-shdwcp` mode contains some additional, optional commands:

- The [report \(gbl-ns-vol-shdwcp\)](#) command enables the shadow-copy rule to generate a report every time a shadow copy occurs. Reports are recommended, to keep a running log of all shadow copies.
- The optional [delta-threshold](#) command changes the minimum size of a file to be *delta-transferred* (as opposed to entirely transferred) to the shadow volume.
- You can use the [publish group](#) command to back out any shadow copy where any of its files fails to transfer properly.
- The optional [bandwidth-limit](#) command sets a limit on the amount of bandwidth used when the rule runs.
- After the initial run of the rule, it goes through a pruning phase to find extra files and directories at the target and remove them. If you are sure that the target has no extra files or directories, you can use the `no prune-target` command to avoid this extra processing.

**Guidelines:  
Shadow-Volume  
Targets**

To create a shadow volume, use the `gbl-ns-vol shadow` command at the target switch. This command changes a standard volume into a shadow volume.

To copy a source volume to multiple shadow-volume targets, configure one `shadow-copy-rule` for each target.

**Guidelines: Schedule**

To create a schedule to be applied to the shadow-copy rule, use the `gbl schedule` command at the source switch. The rule fires as dictated by its schedule: if the schedule has a start time that is earlier than now, the first shadow copy begins as soon as you enable the rule.

If you make a configuration change when the rule is running on a schedule, the configuration change is ineffective until the next time the rule runs. This includes changes to the rule’s behavior between scheduled runs, such as a change to [inline-notify](#) behavior. You can make the change take effect immediately by using `no enable \(gbl-ns-vol-shdwcp\)` followed by `enable` on the rule.

**Guidelines: Reports**

As mentioned above, we recommend that you use the shadow-copy `report` feature to keep a detailed log of all shadow copies. The reports appear on the source switch: the `show reports` command shows all reports on the switch, including shadow-copy reports. You can use the standard file-management commands with these reports: `delete`, `rename`, `show reports file-name`, `tail`, and/or `grep`.

---

**Sample** `prtlnA(gbl-ns-vol[wwmed~/acct])# shadow-copy-rule SVrule`  
This will create a new policy object.

Create object 'SVrule'? [yes/no] **yes**  
`prtlnA(gbl-ns-vol-shdwcp[wwmed~/acct~SVrule])#`  
instantiates a new shadow-copy rule, "SVrule," for the current volume.

## show shadow

**Purpose** Use the `show shadow` command to see the current status of one or more shadow-copy rules.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show shadow`  
`show shadow namespace`  
`show shadow namespace vol-path`  
`show shadow namespace vol-path rule-name`

*namespace* (1-30 characters) identifies the namespace with the source volume.

*vol-path* (1-1024 characters) focuses on one source volume in the namespace.

*rule-name* (1-1024 characters) focuses on one rule.

**Guidelines** Each rule starts with the following fields, for identification:

Namespace

Source Volume

Shadow Rule

Report File, where the prefix is chosen by the `report (gbl-ns-vol-shdwcp)` command.

Fileset, which is chosen by the `from fileset (gbl-ns-vol-shdwcp)` command.

Delta Threshold shows the minimum size for a file to qualify for delta-transfers. A delta transfer is a copy of only the changed portions of a file. This is set with the `delta-threshold` command.

Publishing Mode indicates whether or not all of the files are published together as a “group” if (and only if) all of them are successfully transferred. This can be “group” or “individual,” as set by the `publish` command.

CIFS SID Translation is “Fail on Errors,” “Ignore Errors,” or “Disabled.” If either of the first two options, the shadow-copy rule translates CIFS Security IDs (SIDs) from source-volume filers to their equivalent SIDs at the shadow-volume filers. This enables local-group support at both filers. “Fail on Errors” indicates that the rule refuses to copy any file or directory where the SID translation fails. You control this with the `sid-translation (gbl-ns-vol-shdwcp)` command.

Shared Access Allowed indicates that the shadow-copy rule allows other applications to write to a file during the copy operation. This makes it possible for the rule to copy an open file.

Inline Notifications appears if the shadow-copy rule monitors the source volume for inline changes. An *inline change* is one that occurs due to a client operation, such as a file rename. If the rule tracks these changes, it can avoid a full scan of the source volume the next time the rule runs. Use the `inline-notify` command to set this.

Prune Target only appears if the rule prunes empty directories from the target volume after a successful shadow copy. Use the `prune-target` command to determine this.

---

**Guidelines (Cont.)**

**Bandwidth Limit** only appears if it was set with the [bandwidth-limit](#) command.

**Retry Attempts** shows the number of retries the rule makes if a shadow-copy run is interrupted by a network disconnect. This only applies to a rule with a target volume on another ARX. Use the [retry attempts](#) command to change this number.

**Retry Delay** shows the number of seconds between retry attempts. Use the [retry delay](#) command to change this time.

**Database Location** is either “metadata-share” or “volume.” This indicates where the shadow-copy rule keeps its database. A setting of “metadata-share” is recommended. Use the [database-location](#) command to change this setting.

**CIFS 8dot3 Resolution** appears if the rule can copy files with “8.3” names that collide with other files at the shadow volume. This is recommended for all shadow-copy rules in volumes that support CIFS. Use the [cifs-8dot3-resolution](#) command to set this.

These are followed by three fields to show the latest run time and status for the rule:

**Processing Started** states the date and time.

**Processing Completed** only appears when the shadow copy has concluded.

**Elapsed Time** is stated in hours, minutes, seconds.

The next several fields describe the shadow-copy run at a high level:

**Operating Mode** is “Full tree walk” (examine the full source-volume tree with every shadow-copy session) or “Inline notification” (keep track of directories that change between shadow copies, and only examine the changed directories on the next shadow copy). Use the [inline-notify](#) command to change the mode.

**Tree Walk Reason** is present if the shadow volume rule is performing a full tree walk of the source volume (instead of using inline notification of changes) and indicates why the tree walk is being performed. Possible reasons include:

- **Initial run** means that it is the first run of the rule, so a tree walk is necessary.
- **Initial run (resumed)** is caused by the ARX rebooting before the first tree-walk completes.
- **Rule started** indicates the rule was disabled and then re-enabled.
- **Rule modified** indicates the rule parameters changed.
- **Publishing database rebuild** is caused by an [nsck ... rebuild](#) of the source or target volume requiring the target’s publishing database to be rebuilt.
- **Inline notification overflow** occurs if a large number of notification events were generated and the database used to store these events overflowed.
- **Previous run failed** indicates the previous run of the rule encountered an error.
- **Inline notification disabled** indicates that someone used no [inline-notify](#) to disable inline notification.

**Source Status** appears if there is a problem with the source volume. The problem is summarized here.

**Current Phase** shows the phase of the current shadow-copy run. See [Guidelines: Shadow-Copy Phases](#) for a list of all possible settings in this field.

### Guidelines (Cont.)

Target Information lists the target for the current shadow-copy rule. This shows the status of the most-recent (or current) shadow copy to the target volume. See [Guidelines: Target Status](#) for a list of all possible status settings.

Copy Phase Information shows details about the copy phase. This is when the rule copies all files from the source volume to the shadow volume. If **publish group** is in effect, all files must copy successfully before going into “Publishing” phase, below.

Publishing Phase Information shows the files that have moved to the final locations. If **publish group** is in effect, this phase does not start until the Copy Phase ends. If the rule is set to **publish individual**, this table updates in tandem with the Copy Phase table.

Pruning Phase Information appears only for the first run of the shadow-copy rule, if at all. In this phase, the shadow volume scans its directory tree and prunes away all files and directories that are not on the source volume, too. For cases where the source and shadow volumes are known to be identical from the outset, you can disable this phase with **no prune-target**.

Cleaning Phase Information also appears very rarely. This means removing empty directories and files that the shadow-copy rule created in the staging area. This is only necessary in a limited number of cases.

### Guidelines: Shadow-Copy Phases

Current Phase goes through the following settings, in order:

- **Inactive** - The rule is enabled, but has not yet run.
- **Initializing** - The rule is starting.
- **Connecting** - The source switch is connecting to the target switch.
- **Opening Database** - The rule is opening a database at the target switch.
- **Reindexing Database** only occurs rarely, after a software upgrade or a failure at the target site. The rule is writing an index file for fast access to the target database.
- **Copying then Publishing, or Copying/Publishing** - The Copying phase is when the rule copies files from the source volume to a *staging area* on the shadow volume. All files must copy successfully before the rule enters its Publishing phase. During the Publishing phase, the rule moves the files from the staging area to their final locations. These two phases occur when **publish group** is in effect. If **publish** is set to **individual**, this phase is **Copying/Publishing**; each file is copied to the staging area and then immediately moved to its final location.
- **Pruning** appears only for the first run of the shadow-copy rule, if at all. In this phase, the shadow volume scans its directory tree and prunes away all files and directories that are not on the source volume, too. For cases where the source and shadow volumes are known to be identical from the outset, you can disable this phase with the **no prune-target** command.
- **Cleaning** also appears very rarely. This means removing empty directories and files from a staging area behind the target volume. This is only necessary in a limited number of cases.
- **Closing Database** is the final step before a completed run.
- **Completed** - The operation is finished. Success or failure is indicated under **Target Information**, below.

Some phases may go by too quickly for you to ever see them on this screen. If the phase is **Unknown**, there may be a system anomaly. **Disabled** appears if the shadow-copy rule is disabled.

---

|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Guidelines: Target Status</b> | <p>The Target Information field shows the status of the most-recent (or current) shadow copy to the target volume:</p> <ul style="list-style-type: none"><li>• <b>Successful</b> indicates that the shadow-copy run finished and completely succeeded.</li><li>• <b>Error(s) detected</b> means that some problem occurred. Details appear in the shadow-copy report for the run. The <a href="#">show reports</a> command shows all reports on the switch, including shadow-copy reports.</li><li>• <b>Unable to establish connection</b> indicates that the remote switch is unreachable through the Resilient Overlay Network (RON). Use <a href="#">show ron</a> to view the status of your RON connections.</li><li>• <b>Error(s) detected, Connection failed</b> shows that the RON connection with the remote switch was lost after the shadow-copy run started. As above, use <a href="#">show ron</a> to view the status of your RON connections.</li><li>• <b>Target volume is offline</b> indicates a problem at the remote ARX. Use <a href="#">show namespace</a> at the remote ARX to find the status of the shadow volume.</li><li>• <b>Target is not a shadow volume</b> means that the shadow-copy rule has the wrong <a href="#">target (gbl-ns-vol-shdwcp)</a>, or that the target volume itself is not configured as a shadow volume. To convert a managed volume to a shadow volume, use the <a href="#">shadow</a> command.</li><li>• <b>Target volume is no modify</b> shows that the shadow volume has the <a href="#">no modify</a> setting. This prevents the shadow-copy rule from writing to the shadow volume. At the target switch, you can use the <a href="#">modify</a> command in the shadow volume to allow write access.</li><li>• <b>Target volume has insufficient space</b> indicates that the file servers behind the shadow volume do not have enough space to hold a replica of the source volume. Consider using a larger share behind the shadow volume, or adding additional shares.</li><li>• <b>Target host does not exist,</b></li><li>• <b>Target namespace does not exist, and</b></li><li>• <b>Target volume does not exist</b> all indicate a bad target in the shadow-copy rule. Use the <a href="#">target (gbl-ns-vol-shdwcp)</a> command to change the shadow-volume target.</li><li>• <b>Target volume is unavailable</b> indicates a problem at the remote ARX. Use <a href="#">show namespace</a> at the remote ARX to find the status of the shadow volume.</li><li>• <b>Target host is not reachable</b> indicates that the remote switch is unreachable through the network. Use the <a href="#">ping</a> command and/or <a href="#">expect traceroute</a> to check the connection to the remote ARX.</li><li>• <b>Target version not supported</b> means that the software release on the target ARX is incompatible with the release on the source ARX. From either CLI, use <a href="#">show version</a> to see the currently-running release of software. You can install new software through the CLI; refer to the <a href="#">ARX CLI Maintenance Guide</a> for software-upgrade instructions.</li></ul> |
| <b>Sample</b>                    | <pre>bstnA# show shadow wwmed</pre> <p>shows the status of all shadow copies from the wwmed namespace. See <a href="#">Figure 29.2 on page 29-28</a> for sample output.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## sid-translation (gbl-ns-vol-shdwcp)

**Purpose** Behind either the source or the shadow volume, one of the back-end CIFS filers may be configured for *Local Groups*. These filers use local Security IDs (SIDs) for their group names instead of those issued by a Domain Controller (DC). You can configure a shadow-copy rule to translate all local SIDs to their corresponding names at the source filer, then translate the names back to SIDs at the target filer. This preserves local-group privileges, so that members of a local group at the source filer can access copies of their files and directories at the shadow volume. Use the `sid-translation` command to enable SID translation for the current rule. Use `no sid-translation` to disable SID translation for this shadow-copy rule.

**Mode** gbl-ns-vol-shdwcp

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `sid-translation [fail-on-errors]`  
`no sid-translation`

`fail-on-errors` (optional) causes the rule to abort any file or directory copy where the SID translation fails. Translation failures can occur if a local group on the source filer does not exist on the target filer. For SID translation to reliably succeed, all local groups on the source volume's filers must be duplicated on the shadow volume's filers. If SID translation fails and you omitted this option, the rule copies the SID to the shadow volume without translating it; the Access-Control Entry (ACE) is therefore unusable while on the shadow volume, though it *will* be usable if someone later copies the file back to the source volume.

**Default(s)** `no sid-translation`

**Guidelines** This command does not apply to a rule in an NFS-only namespace.

While SID translation is enabled, the rule translates each SID to a group name (at the source volume), then translates the group name back to a SID (at the target volume). This ensures that the final SID is one that is properly configured at the shadow volume.

SID translations are only needed if

- any filers behind the source volume have local groups defined, and
- CIFS clients in those local groups require read access to the files at the shadow volume.

Before you enable SID translations, all filers behind both volumes should support all of each other's local-group names. These are the filers behind the source volume *and* the shadow volume. If a file tagged with local-group name, "staff", is copied to remote filer without any definition for a "staff" group, the shadow-copy rule copies the SID for "staff" verbatim; this SID will be unusable at the destination filer. To avoid these translation failures, duplicate all local group names and user names on all of the filers behind both volumes.

The gbl-ns-vol-shr [ignore-sid-errors](#) command is designed for filers that return an error for an unknown SID but accept the file or directory anyway. If this is set for a share in the shadow volume, the shadow-copy rule ignores SID errors from that filer, even if you used [fail-on-errors](#) in the [sid-translation](#) command.

If the source and shadow volume are in two different Windows domains, your site may require additional preparation. Contact F5 Support if you want to configure SID translation for an inter-domain shadow-copy rule.

Use the gbl-ns-vol-shr [sid-translation](#) command to perform SID translations for file migrations within the volume.

**Sample**

```
bstnA(gbl-ns-vol-shdwcpc[wwmed~/acct~SVrule])# sid-translation
```

  
enables SID translation for the rule named "SVrule."

## target (gbl-ns-vol-shdwcp)

**Purpose** Use the `target` command to choose a shadow-volume target for the current shadow-copy rule. A shadow-copy rule copies a fileset from the current volume to a shadow volume.

**Mode** gbl-ns-vol-shdwcp

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `target [hostname host [namespace name]] volume shadow [path sub-path]`

**hostname *host*** (optional, 1-32 characters) identifies the host for the shadow volume. The shadow volume must reside on the current switch or another ARX in the same RON. Use the `show ron` command to view all hosts in the RON.

**namespace *name*** (optional, 1-30 characters) identifies the shadow volume's namespace.

***shadow*** (1-256 characters) identifies the shadow volume itself.

**path *sub-path*** (optional, 1-1024 characters) selects a subdirectory in the shadow volume.

**Default(s)** *host* - the local switch  
*name* - the current namespace

**Guidelines** This command sets a storage target for the current shadow-copy rule.

A target volume must be configured as a shadow volume; use the `gbl-ns-vol shadow` command to change a standard volume into a read-only shadow volume. To use another switch as the host for the shadow volume, log into the CLI on that switch and add the volume from there.

To consolidate multiple shadow copies into a single volume, use the optional **path** argument. Multiple volumes can use the same shadow volume as a target, where each source volume is copied to a unique path. For example, the `/etc` volume can have a target volume and path of `/shadow/etc` while the `/var` volume has a target and path of `/shadow/var`. Both source volumes are thereby copied to the `/shadow` volume. This simplifies backups for the two volumes.

If you use paths, do not overlap them. For example, you cannot use a target of `/shadow/var` for one source volume in addition to `/shadow/var/log` for another.

A target volume must support all of the protocols for its source volume(s). For example, an NFSv3 and CIFS volume can be a shadow target for another volume with both of those protocols, or for a CIFS-only volume, or for an NFSv3 volume. It cannot be the target for an NFSv2 volume.

If the volume contains any imported NetApp share with multiple qtrees, it cannot be used as the source or target of a shadow-copy rule. This is not an issue if each NetApp share is a single qtree, or if none of the NetApp shares contain any qtrees.

**Samples** `bstnA(gbl-ns-vol-shdwcp[wmed~/acct~SVrule])# target hostname prtlnA namespace nemed volume /acctShadow`  
uses /acctShadow as the target for “SVrule.” This shadow volume resides on a remote switch, “prtlnA,” in the same RON.

`bstnA(gbl-ns-vol-shdwcp[archives~/usr~buUsers])# target namespace allBackups volume /bu path /usr`  
uses “allBackups~/bu/usr” as the target for the “buUsers” rule.

`bstnA(gbl-ns-vol-shdwcp[archives~/log~buLogs])# target namespace allBackups volume /bu path /log`  
uses “allBackups~/bu/log” as the target for the “buLogs” rule.

**Related Commands** [shadow-copy-rule](#)

Snapshots

---

---

---

# clear statistics snapshot

**Purpose** Volumes keep statistics on all of their snapshot operations. A *snapshot* is a full copy of the volume at a particular moment in time. A *snapshot rule* determines the names for a set of snapshots, the number of snapshots to retain, and (optionally) a schedule for taking snapshots. Use this command to clear the cumulative statistics for a particular snapshot rule.

**Mode** priv-exec

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `clear statistics snapshot namespace volume snapshot-rule`

*namespace* (1-30 characters) identifies a namespace.

*volume* (1-1024 characters) is a volume that supports snapshots.

*snapshot-rule* (1-1024 characters) is the rule whose statistics should be cleared.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before clearing any snapshot statistics. Enter **yes** to proceed.

The [show policy ... details](#) command shows cumulative statistics for snapshot operations. Use this command to clear the statistical counters for one snapshot rule.

**Sample** `bstnA# clear statistics snapshot medarcv /lab_equipment dailySnap`

Confirming this command causes all historic statistical data for the snapshot rule to be reset.

Proceed? [yes/no] **yes**

clears all snapshot statistics for the “dailySnap” rule.

**Related Commands** [show policy](#)

## enable (gbl-ns-vol-...snap)

|                         |                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | <p>A <i>snapshot rule</i> is the basic configuration object for taking snapshots, or point-in-time copies, of an ARX volume. ---

## exclude

**Purpose** You can use the `exclude` command to exclude a particular volume share from the current snapshot or replica-snap rule.  
Use `no exclude` to return to including a share in this volume's coordinated snapshots.

**Mode** `gbl-ns-vol-snap`  
`gbl-ns-vol-replica-snap`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `exclude share-name`  
`no exclude share-name`

*share-name* (1-64) identifies the share to exclude. This is the share name from the ARX-volume configuration, not the filer configuration.

**Default(s)** `no exclude`

**Guidelines** The `no manage snapshots` command excludes an entire filer from any ARX-snapshot operations, typically because the filer does not support ARX snapshots. That command is sufficient for most installations. Use this command, `exclude`, only under the advisement of F5 Support; it creates sparse snapshots that may be an issue later if clients need files restored. It is intended for filers where a particular back-end volume or file system is near capacity, but others on the same filer are not.

By default, a snapshot rule creates snapshots on all of the back-end shares that support them. You configure a filer to support snapshots with some external-filer commands, such as `filer-type` and `manage snapshots`. For back-end volumes that are currently nearing their full capacity, you can use this command to exclude them from this rule's snapshots. The negative form of the command, `no exclude`, can later re-instate the share for inclusion in ARX snapshots.

Files in an excluded share do not appear in the volume's coordinated snapshot(s). For example, if the excluded share contains "`\bigDir\bigFile.wmv`," clients cannot recover "`bigFile.wmv`" from the ARX view of the snapshot. If this is a concern at your site, you can use one or more [place-rules](#) to control which files reside on your excluded shares. We recommend that you contact F5 Support for specific guidance.

**Guidelines: Snapshot Rules and Replica-Snap rules** A [snapshot rule](#) coordinates the snapshots on your standard back-end shares, and a [snapshot replica-snap-rule](#) coordinates snapshots on special [replica-snap](#) shares. A replica-snap share is a replica of one of the managed-volume's standard shares on a cheaper filer; the cheaper filer creates and stores an ever-growing collection of snapshots from that replicated share. From the perspective of an ARX client, standard snapshots are interleaved with replica snaps, and the two snapshot types are indistinguishable.

A snapshot rule always excludes all replica-snap shares, and a replica-snap rule always excludes all standard snapshot shares. The `exclude` command cannot change these rules. For example, you can exclude a replica-snap share from a replica-snap rule, but you cannot exclude the same share from a standard snapshot rule; it is already excluded by definition.

**Sample** `bstnA(gbl-ns-vol-snap[access~/G~daily])# exclude ronin4`  
excludes the “ronin4” share from the snapshot rule named “daily.”

**Related Commands** [namespace](#) -> [volume](#) -> [snapshot rule](#)  
[namespace](#) -> [volume](#) -> [snapshot replica-snap-rule](#)

---

## report (gbl-ns-vol-...snap)

**Purpose** Use this command to enable progress reports for the current snapshot or replica-snap rule.

Use `no report` to prevent progress reports.

**Mode** gbl-ns-vol-snap  
gbl-ns-vol-replica-snap

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `report file-prefix`  
`no report`

*file-prefix* (1-1024 characters) sets a prefix for all snapshot reports. We recommend starting all of your snapshot-report prefixes with a common string, such as “snap\_”; this commonality helps you to prepare for snapshot reconstitution (described below). Each report has a unique name in the following format:

*file-prefix\_0\_create\_YearMonthDayHourMinuteSecondsMilliseconds.rpt*

For example, `snap_nightly_0_create_20070930130022142.rpt` could be the name for one report with the prefix, “snap\_nightly.”

**Default(s)** `no report`

**Guidelines** Every time a snapshot or replica-snap rule fires and creates a coordinated snapshot, the rule can generate a report to show the details of the snapshot-create operation. This includes details about each snapshot at each of the volume’s back-end filers. The reporting feature is disabled by default; we recommend that you enable reporting for all snapshot and replica-snap rules, to diagnose any problems that occur with snapshots and to make snapshot reconstitution possible.

Use [show reports](#) for a list of reports, or `show reports file-name` to show the contents of one report.

See [Figure 30.1 on page 30-9](#) for a sample snapshot-create report.

**Guidelines: Preparing  
for Snapshot  
Reconstitution**

There are situations that require a transfer of coordinated snapshots from one ARX to another, such as the transfer from the ARX at a primary site to another at a disaster-recovery site (see [cluster-name](#) and [activate configs](#) for details about site-to-site failovers). A challenge for this task is mapping multiple back-end snapshots to each ARX snapshot. The process of *snapshot reconstitution* meets this challenge by parsing snapshot reports and producing a CLI script of [snapshot manage](#) commands. Each `snapshot manage` command in the CLI script pulls one back-end snapshot into its corresponding ARX snapshot.

To prepare for snapshot reconstitution, save a copy of every snapshot report and replica-snap report. Use the `at` command together with [copy ftp](#), [copy scp](#), [copy tftp](#), or [copy smtp](#) to regularly copy snapshot reports off of the ARX. Use the common string for all of your snapshot reports, together with an “\*” or other wildcard. The report repository should always hold the latest snapshot reports, so that they have the latest back-end snapshot names. For example, this command copies all reports starting with “snap” to an external IP each morning:

```
bstnA(cfg)# at 01:19:18 every 1 day do "copy reports snap*
ftp://ftpusers:ftpusers@172.16.100.183//var/arxSnapRpts/ format xml"
```

The scheduled execution time for CLI command is: 3/30/09 1:19 AM.

You also need a copy of the “snap-recon.pl” script from the “software” directory on the ARX:

```
bstnA# copy software snap-recon.pl
ftp://ftpusers:ftpusers@172.16.100.183//var/arxSnapRpts/
```

Choose a filer with a large amount of free space, or monitor the filer’s space frequently and remove outdated snapshot reports. Every snapshot report has a timestamp in its name, so it is unique.

The filer should be able to run Perl scripts, and requires the XML::Simple module. You can download this Perl module from CPAN (<http://search.cpan.org>) if your system does not already have it.

**Guidelines:  
Reconstituting ARX  
Snapshots**

You can perform snapshot reconstitution if you have the `snap-recon.pl` script and the latest set of snapshot reports on a host that supports Perl. Start by running the `snap-recon.pl` script on that host. This produces a CLI script with a sequence of [snapshot manage](#) commands. By default, the output script is named, “`snapRecon.cli`.” This script has several options; execute the command without any options to get a complete list. You must use the “`--report-dir directory`” clause to specify the *directory* that holds the reports. For example, this command sequence lists the files on “`client2:/var/arxSnapRpts`,” runs `snap-recon.pl` on the reports in the current directory (`.`), and then shows the new file in the directory:

```
juser@client2:/var/arxSnapRpts$ ls
snap_daily_0_create_20090330010418883.xml snap_hourly_0_create_20090330010652616.xml
snap_daily_0_create_20090330010454303.xml snap_hourly_0_create_20090330010723024.xml
snap_daily_0_create_20090330010524663.xml snap-recon.pl
snap_daily_2_remove_20090330010612220.xml
juser@client2:/var/arxSnapRpts$./snap-recon.pl --report-dir .
juser@client2:/var/arxSnapRpts$ ls
snap_daily_0_create_20090330010418883.xml snap_hourly_0_create_20090330010652616.xml
snap_daily_0_create_20090330010454303.xml snap_hourly_0_create_20090330010723024.xml
snap_daily_0_create_20090330010524663.xml snapRecon.cli
snap_daily_2_remove_20090330010612220.xml snap-recon.pl
juser@client2:/var/arxSnapRpts$
```

**Guidelines:** You have the option to edit the CLI script before you run it on the ARX. For example, the ARX volumes at a disaster-recovery site may have different names than those at the primary site. The `snapRecon.cli` script has several options for substituting these names; you can use these to rebuild the CLI script, or you can manually edit the CLI script.

**Reconstituting ARX Snapshots (Cont.)**

Once the CLI script is ready, you can download it to the ARX and run it. Use `copy ftp`, `copy {nfs|cifs}`, or `copy scp` for the download, and use `run` to run it.

A large, complex CLI script may contain errors. If you discover any back-end snapshots that are mismatched with their ARX counterparts, you can use the `snapshot clear` command to remove the ARX snapshot (not the rule) from the configuration. Then you can edit and re-run the script, or you can use `snapshot manage` to manually incorporate the back-end snapshots into the correct ARX snapshots.

**Samples** `bstnA(gbl-ns-vol-snap[access~/G~nightly])# report snap_G`  
enables reports for the snapshot rule, “nightly.”

`bstnA(gbl-ns-vol-snap[access~/G~fileHist])# report fh_G error-only`  
enables reports for the snapshot rule, “fileHist.” This rule, presumably designed to record file-history information, only generates reports for snapshots with errors.

CIFS Share: xraysScanners  
Reason: Snapshots were not supported on this type of back-end filer.

---

## retain

**Purpose** Each snapshot rule retains some maximum number of *snapshots*, or point-in-time copies, of its volume's files. Use this command to set the number of retained snapshots for the current rule.

Use `no retain` to revert to the default retention count.

**Modes** `gbl-ns-vol-snap`  
`gbl-ns-vol-replica-snap`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `retain snap-count`  
`no retain`

*snap-count* (1-1024) is the maximum number of snapshots for this rule to retain.

**Default(s)** 3

**Guidelines** Whenever the snapshot rule runs, it creates a new snapshot "0" (zero). The former snapshot "0" becomes snapshot "1," the former snapshot "1" becomes snapshot "2," and so on. The rule deletes the oldest snapshot if keeping it would exceed the retain count. For example, if the rule retains 5 snapshots, it only keeps snapshots 0-4. It removes the older snapshots from client presentations as well as the back-end filers. This prevents wasted snapshot space on the filers.

If you increase the retention count in a rule that already has a full count of snapshots, the rule does not delete any snapshots until it exceeds the count again. For example, if the retain count increases from three to four, the next time the rule runs it moves snapshot "3" to "4" and does not delete any snapshots. On the following run of the rule, it deletes snapshot "4" to avoid exceeding the retain count.

If you decrease the retain count in a rule that has already reached it, the volume removes all excess snapshots the next time the rule runs. The CLI prompts for confirmation before accepting this directive.

**Guidelines: Snapshot Rules and Replica-Snap rules** A [snapshot rule](#) coordinates the snapshots on your standard back-end shares, and a [snapshot replica-snap-rule](#) coordinates snapshots on special [replica-snap](#) shares. A [replica-snap](#) share is a replica of one of the managed-volume's standard shares on a cheaper filer; the cheaper filer creates and stores an ever-growing collection of snapshots from that replicated share. From the perspective of an ARX client, standard snapshots are interleaved with replica snaps, and the two snapshot types are indistinguishable.

The replica-snap filer(s) are designed to hold larger numbers of snapshots than standard shares, so we recommend a much higher retain count for a [snapshot replica-snap-rule](#) than a [snapshot rule](#).

**Sample** `bstnA(gbl-ns-vol-snap[access~/G~nightly])# retain 7`  
retains seven snapshots for the rule named "nightly."

**Related Commands** `namespace -> volume -> snapshot rule`  
`namespace -> volume -> snapshot replica-snap-rule`

## schedule (gbl-ns-vol-...snap)

|                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                                           | Use this <code>schedule</code> command to assign a schedule to the current snapshot (or replica-snap) rule.<br>Use <code>no schedule</code> to remove the rule's schedule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Mode</b>                                              | <code>gbl-ns-vol-snap</code><br><code>gbl-ns-vol-replica-snap</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Security Role(s)</b>                                  | storage-engineer or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>                                            | <code>schedule name</code><br><code>no schedule</code><br><br><i>name</i> (1-64 characters) identifies the schedule. Use <code>show schedule</code> for a list of configured schedules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default(s)</b>                                        | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Guidelines</b>                                        | A snapshot rule can take <i>snapshots</i> (point-in-time copies) of an ARX volume on a regular schedule. This command determines which schedule to use, if any.<br>Whether or not a schedule is assigned to the snapshot (or replica-snap) rule, you can manually invoke snapshots with the <code>snapshot create</code> command.<br>To create a schedule, use the gbl-mode <code>schedule</code> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Guidelines: Snapshot Grouping</b>                     | If more than one volume uses the same schedule, the ARX aggregates all of the filer snapshots at once. This is called <i>snapshot grouping</i> . By grouping the filer snapshots, the ARX avoids any duplicate snapshots on a given back-end volume.<br>Snapshot grouping may create a problem for volumes backed by EMC Celerra servers, which serialize their snapshots. Consider a site with 10 volumes backed by 10 different back-end volumes on a single EMC server. If all 10 ARX volumes use the same snapshot schedule, each ARX snapshot must wait for all 10 EMC checkpoints to finish, one after the other.<br>Each ARX volume must use the same schedule (by name) for snapshot grouping to occur. If you use schedules with different names but the same dates and times, the ARX volumes independently perform their snapshot operations. This could result in duplicate snapshots on the same back-end volume, but it avoids the EMC-serialization issue. |
| <b>Guidelines: Snapshot Rules and Replica-Snap rules</b> | A <code>snapshot rule</code> coordinates the snapshots on your standard back-end shares, and a <code>snapshot replica-snap-rule</code> coordinates snapshots on special <code>replica-snap</code> shares. A replica-snap share is a replica of one of the managed-volume's standard shares on a cheaper filer; the cheaper filer creates and stores an ever-growing collection of snapshots from that replicated share. From the perspective of an ARX client, standard snapshots are interleaved with replica snaps, and the two snapshot types are indistinguishable.<br>We recommend using a different schedule (by name) for a replica-snap rule than you use for a standard snapshot rule. The snapshot grouping (above) should be different between snapshot shares and replica-snap shares.                                                                                                                                                                        |

---

**Samples** `bstnA(gbl-ns-vol-snap[access~/G~nightly])# schedule daily4am`  
uses a schedule named “daily4am” for the “nightly” snapshot rule.

`bstnA(gbl-ns-vol-snap[medarcv~/lab_equipment~test_snap])# no schedule`  
removes any schedule from the “test\_snap” rule.

**Related Commands** [namespace](#) -> [volume](#) -> [snapshot rule](#)  
[namespace](#) -> [volume](#) -> [snapshot replica-snap-rule](#)  
[snapshot create](#)  
[schedule](#)  
[show schedule](#)

## show snapshots

**Purpose** Use the `show snapshots` command to see the current status of one or more snapshot rules. This shows snapshots that have been created by a [snapshot rule](#), not snapshots created at the back-end filer.

**Mode** (any)

**Security Role(s)** operator or backup-operator (any)

**Syntax** `show snapshots`  
`show snapshots namespace`  
`show snapshots namespace vol-path`  
`show snapshots namespace vol-path snapshot-rule`

*namespace* (1-30 characters) identifies the namespace with the snapshot rule(s).

*vol-path* (1-1024 characters) focuses on one volume in the namespace.

*snapshot-rule* (1-1024 characters) focuses on one snapshot rule. This changes the output to a detailed view of the rule.

**Guidelines: Summary View** The simplest output shows a summary of all selected *snapshots*, or point-in-time copies of an ARX volume. For each volume, this contains a table with one line per snapshot. Each line contains the following fields:

**Rule** identifies the rule.

**Type** is the particular type of snapshot rule: Snapshot ([snapshot rule](#)), Replica ([snapshot replica-snap-rule](#)), or Notification ([notification rule](#)).

**Name** is the name of the particular ARX snapshot. This is typically the rule name with an integer ID that indicates the order of the snapshots (“0” is the newest, “1” is the next-newest, and so on).

**Created** indicates the time when the final filer finished its snapshot. If a snapshot is currently underway, or if the most-recent snapshot incurred an error, the current status appears in this field:

- **Requested** means that someone issued a [snapshot create](#) command, or that the rule’s schedule just invoked a new snapshot.
- **In Progress** indicates that a snapshot is currently underway at the back-end filers.
- **Incomplete** means that the fencing timeout expired before the snapshot finished on all of its included back-end filers. This implies that [snapshot consistency](#) is enabled, causing the volume’s VIP(s) to put up a *fence* against client access until the snapshots finish.
- **Fence failed** also implies that [snapshot consistency](#) is enabled, and means that the VIP failed to raise its fence against client access. This indicates an internal-software error; contact F5 Support if you see this.
- **Policy pause failed** indicates another internal-software error, and should not appear during normal operation. As above, contact F5 Support if you see this.

**Guidelines: Summary View (Cont.)**

- **Failed** indicates that the snapshot operation failed at one or more back-end filers or servers. Check the snapshot report (available in the detailed output) for more details.

Source is “Schedule” or “Manual.”

- **Schedule** indicates that the snapshot was invoked by the snapshot rule’s [schedule \(gbl-ns-vol-...snap\)](#), and
- **Manual** means that an administrator manually invoked a snapshot with the [snapshot create](#) command.

**Guidelines: “Snapshot Rule Summary” in Detailed View**

The detailed view of a snapshot rule appears when you specify the rule in the command. This shows two tables: “Snapshot Rule Summary” and “Snapshot Properties.”

The “Snapshot Rule Summary” table summarizes the rule configuration:

Namespace Name,

Volume Name, and

Snapshot Rule Name are defined by the [snapshot rule](#) command.

**Guidelines: “Snapshot Properties”**

The “Snapshot Properties” Table provides details about the snapshot configuration:

**Snapshots Enabled** is “Yes” or “No,” depending on the setting for [enable \(gbl-ns-vol-...snap\)](#).

**Guarantee Consistency** is “Enabled” or “Disabled,” depending on whether or not the volume uses VIP fencing for its snapshots. The VIP fence, if enabled, blocks all client access to the volume while the filers take their coordinated snapshots. Use the [snapshot consistency](#) command to allow or disallow this fence.

**Retain Count** is the number of snapshots to retain for this rule. If the volume has this many snapshots when it takes a new one, it moves all of the snapshots to the next slot down and then deletes the oldest snapshot. For example, it creates a new “nightly\_0” snapshot, moves the old “nightly\_0” to “nightly\_1,” and so on, until it reaches the retain count; then it deletes any remaining snapshots. You can control this with the [retain](#) command.

**Schedule** is the name of the schedule for the snapshot rule, if any. Use the [schedule \(gbl-ns-vol-...snap\)](#) command to assign a schedule to the snapshot rule.

**CIFS Directory Name** only appears if the volume supports CIFS. This is the pseudo directory that well-informed CIFS clients (administrators) can use to access their snapshots. You can use the [snapshot directory cifs-name](#) command to change this name.

**NFS Directory Name** only appears if the volume supports NFS. This is the pseudo directory that well-informed NFS clients (administrators) can use to access their snapshots. You can use the [snapshot directory nfs-name](#) command to change this name.

**Directory Display** is “All Exports” (clients see the ~snapshot/.snapshot directory in any front-end share), “Volume Root Only” (clients only see the directory only in a front-end share of the volume’s root directory) or “None.” You can use the [snapshot directory display](#) command to change this.

**Guidelines:  
“Snapshot  
Properties” (Cont.)**

**Hidden File Attribute** only appears if the volume supports CIFS. This is “Set” if the special `~snapshot` directory has its “hidden” DOS attribute raised, or “Not Set” otherwise. Use an optional argument in the [snapshot directory display](#) command to control this setting. This does not hide the `~snapshot` directory from NFS clients.

**Restricted Access Configured** also only appears if the volume supports CIFS. This is “Yes” or “No” depending on whether or not someone used the [snapshot privileged-access](#) command. If this is “Yes,” a small set of privileged CIFS clients can access the volume’s snapshots. These clients are members of a Windows-Management-Authorization (*WMA*) group with permission to monitor snapshots. These privileged clients are typically administrators. This does not limit access by NFS clients in any way.

**VSS Mode** only appears if the volume supports CIFS. This field indicates the client-machine versions for which the volume supports the Volume Shadow-copy Service (*VSS*). VSS is an intuitive interface that Windows clients can use to access their snapshots. This is “Windows XP” (the volume supports VSS for Windows XP client machines, as well as newer machines), “Pre-Windows XP” (the volume also supports VSS for Windows-2000 clients), or “None.” Use the [snapshot vss-mode](#) command to change this setting. Direct volumes do not support VSS, and NFS clients are unaffected by it.

**Contents** is relevant to a snapshot rule that sends its snapshots to a [file-history archive](#). This shows the **contents** of this snapshot. Each of these fields shows one possible type of content with a “Yes” or “No:”

- **Metadata** is the volume’s metadata,
- **Volume Configuration** is the volume-specific data from [show global-config](#), and
- **User Snapshots** are the standard back-end snapshots. For a non-archive snapshot, this is the only content in the snapshot.

**Archive** is also relevant to a snapshot rule that sends its snapshots to a [file-history archive](#). These field show high-level statistics for the rule’s archiving operations.

**Guidelines:  
“Snapshot Summary -  
snapshot-name”**

After the rule has run at least once, additional tables appear for each snapshot. The first table, “Snapshot Summary - *snapshot-name*” summarizes the ARX’s coordinated snapshot. This table contains the following fields:

**Snapshot Name** is the name of the coordinated snapshot.

**Time Requested** is the last date and time that someone issued an ARX command (such as [snapshot create](#) or [snapshot verify](#)) for this coordinated snapshot.

**Time Created** shows the date and time that the last filer behind the volume completed its snapshot or checkpoint operation. “In progress” appears if a snapshot is currently underway.

**Last Time Verified** is the last time someone ran [snapshot verify](#) against this ARX snapshot.

**Guidelines:**  
**“Snapshot Summary -  
 snapshot-name”**  
**(Cont.)**

Request shows the currently-active request for this ARX snapshot. This is one of the following:

- **Idle** indicates that no command is currently running on this snapshot.
- **Create** means the rule is currently creating a coordinated snapshot. This indicates either a scheduled snapshot or a snapshot invoked by the [snapshot create](#) command.
- **Manage** shows that the rule is incorporating an existing snapshot to an ARX snapshot. This means that someone invoked the [snapshot manage](#) command.
- **Delete** indicates that filer snapshots are being removed from behind this rule. This request comes from the [snapshot remove](#) command.
- **Remove** indicates that someone invoked `no snapshot rule` to delete the current snapshot rule.
- **Verify** shows that someone invoked [snapshot verify](#) to verify the integrity of all filer snapshots behind this ARX snapshot.
- **Cleanout** indicates that a snapshot operation failed and the snapshot software is removing filer snapshots that are inconsistent with one another. This should be rare. If you see this, you can use the [show cores](#) command to check for core-memory files from the snapshot software. The clean-out operation generates a snapshot report that you can see with the [show reports](#) command.

**Snapshot State** shows the results of the most-recent snapshot operation. This is either “Complete,” “Sparse,” or “Incomplete.” “Complete” indicates a successful snapshot on all of the volume’s shares. “Sparse” means that at least one of the volume’s shares is excluded from the volume snapshot, either administratively (through `no manage snapshots` or `exclude`) or because the share failed to create its snapshot. An “Incomplete” state only applies to a [snapshot verify](#) operation: this indicates that one of the included shares is now missing its back-end snapshot or checkpoint.

**Snapshot Origin** is “Schedule” or “Manual.” This has the same possible values as the **Source** field in the summary view:

- **Schedule** indicates that the snapshot was invoked by the snapshot rule’s [schedule \(gbl-ns-vol-...snap\)](#), and
- **Manual** means that an administrator manually invoked a snapshot with the [snapshot create](#) command.

**Report Name** identifies the report for the snapshot’s most-recent action. You can use [show reports report-name](#) to view this report.

**Guidelines: “Included Shares”**

A separate table appears under the “Included Shares” heading for each of the shares in this snapshot. These are the component snapshots for the ARX snapshot described above. These snapshots are only the ones created by the ARX snapshot rule or imported into the rule with the `snapshot manage` command; they do not include any snapshots created independently on the filer.

Each table contains the following fields to describe the snapshot on a particular filer:

**Share Name** is the name of the share in the ARX volume, defined by the `share` command.

**Filer** is a header for the remaining fields.

**Name** is the external-filer name, defined with the `external-filer` command.

**NFS Share** is the name of the NFS export at the filer.

**CIFS Share** is the name of the share at the filer.

**Volume** is the name of the filer volume behind the above filer share.

**Volume Snapshot** is the name of the filer snapshot.

**Guidelines: “Excluded Shares” and “Offline Shares”**

If any of the volume’s shares were administratively excluded from the snapshot, an “Excluded Shares” section appears to describe them. You can use `no manage snapshots` to exclude all shares on a filer, or `exclude` to exclude a particular share from the snapshot rule. These tables contain the same fields that are in the “Included Shares” tables, except the fields to describe the back-end snapshot.

If the snapshot operation failed at any of the volume’s back-end share, an “Offline Shares” section appears to describe them. These share tables contain the same fields as those in the “Excluded Shares” section.

**Samples**

`bstnA# show snapshots`

shows a summary of all snapshots on the ARX. See [Figure 30.2](#), below, for sample output.

`bstnA# show snapshots medarcv /lab_equipment hourlySnap`

shows details for the “hourlySnap” rule. See [Figure 30.3 on page 30-19](#) for sample output.

```

## snapshot clear

**Purpose** An ARX volume creates *snapshots*, or point-in-time copies, by coordinating snapshots and/or checkpoints at its back-end filers. Under rare circumstances, you may perform a *snapshot reconstitution* operation to connect (or re-connect) back-end snapshots to ARX snapshots. If the snapshot reconstitution causes a mismatch between the back-end snapshots and their ARX counterparts, you can use the **snapshot clear** command to remove the ARX snapshot(s).

**Modes** priv-exec

**Security Role(s)** storage-engineer, backup-operator, or crypto-officer

**Syntax** **snapshot clear namespace [vol-path [snap-rule [snapshot snap-instance [share share-name]]]]**

*namespace* (1-30 characters) identifies a namespace with one or more snapshot rules.

*vol-path* (optional, 1-1024 characters) is one volume with snapshots. If you omit this, the command removes the configurations for all ARX snapshots in the namespace.

*snap-rule* (optional, 1-1024 characters) is a snapshot rule. This focuses in the snapshots in the chosen rule.

*snap-instance* (optional, 1-255 characters) identifies a particular ARX snapshot. Snapshots are typically named *snap-rule\_n*, where *n* is 0 (zero) for the newest snapshot, 1 for the next-newest, 2 for the snapshot before 1, and so on.

*share-name* (optional, 1-64 characters) focuses on a single ARX share in the above volume. This removes the rule's references to snapshots on this share.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before clearing any snapshots from the ARX configuration; enter **yes** to proceed.

This command is designed for situations where filer snapshots are incorporated into the wrong ARX snapshots. This can occur after a snapshot reconstitution with errors. (For details on snapshot reconstitution, see the Guidelines for the [snapshot rule](#) command.) You can use this command to clear the mismatched ARX snapshots, then you can edit the `snapRecon.cli` script and re-run it. Alternatively, you can use [snapshot manage](#) to re-incorporate one back-end snapshot at a time.

This command is not recommended for many other situations. The [snapshot remove](#) command removes the back-end snapshots behind one or more ARX snapshots, and the `no snapshot rule` command removes the snapshot rules.

**Sample** `bstnA# snapshot clear medarcv /lab_equipment hourlySnap snapshot hourlySnap_2 share backlots`

Confirmation of this command results in the clearing of snapshot 'hourlySnap\_2' for share 'backlots' associated with snapshot rule 'hourlySnap' in namespace 'medarcv' volume '/lab\_equipment'. This command does not remove the snapshot from the filer in the volume.

Proceed? [no] **yes**

clears the record for one snapshot on one back-end share. This applies to the “hourlySnap\_2” snapshot in the ARX configuration; the command clears its reference to a snapshot on the “backlots” volume. This prevents the volume’s clients from accessing any files in that back-end snapshot.

**Related Commands** [snapshot rule](#)  
[snapshot manage](#)  
[snapshot remove](#)

## snapshot consistency

**Purpose** A *snapshot* is a complete, point-in-time copy of an ARX volume. The ARX volume coordinates snapshots at each of its back-end filers; you can use the `snapshot consistency` command to put up a *VIP fence* until the filers finish. Clients cannot access the volume's VIP(s) while the fence is up, so the snapshots are guaranteed to be consistent.

Most installations do not require strict snapshot consistency. Use `no snapshot consistency` to stop using the VIP fence for future snapshots.

**Modes** `gbl-ns-vol`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `snapshot consistency`  
`no snapshot consistency`

**Default(s)** `no snapshot consistency`

**Guidelines** The VIP fence prevents any changes to the volume, which could result in an ARX snapshot that contains redundant or inconsistent files. For example, two filers may take their snapshots at slightly-different times, thus creating slight inconsistencies between the snapshots on each filer. The VIP fence prevents all inconsistencies between filer snapshots; the `snapshot consistency` command causes the volume to use the VIP fence.

### ◆ Important

---

*The consistency fence blocks all access to the volume's VIP or VIPs. It also stops access to the other volumes behind the VIP(s), if there are any, until the fence comes back down.*

The VIP fence stops when the final back-end filer finishes its snapshot, or after a timeout. The ARX snapshot times out after 1 minute, plus 80 seconds for each back-end snapshot. If this volume uses the same snapshot `schedule (gbl-ns-vol-...snap)` as another volume, their snapshots are grouped and this timeout increases by 80 seconds for each additional back-end snapshot. If the timeout expires before all filers have finished their snapshots, the ARX rolls back all filer snapshots.

To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the `snapshot rule` command.

**Samples** `bstnA(gbl-ns-vol[medarcv~/lab_equipment])# snapshot consistency`  
enables VIP fencing in the “medarcv~/lab\_equipment” volume.

`bstnA(gbl-ns-vol[access~/G])# no snapshot consistency`  
disables VIP fencing in the “access~/G” volume. Future snapshots in this volume may have inconsistencies from one back-end snapshot to another.

**Related Commands** [snapshot rule](#)

---

# snapshot create

**Purpose** A *snapshot* is a full copy of a virtual volume at one point in time. A *snapshot rule* defines a name for the snapshots, the maximum number of snapshots to retain under that name, and an optional schedule. Use the `snapshot create` command to manually invoke a snapshot rule, creating a coordinated snapshot at the current point in time.

**Modes** priv-exec

**Security Role(s)** storage-engineer, backup-operator, or crypto-officer

**Syntax** `snapshot create namespace vol-path snapshot-rule [snapshot-instance]`

*namespace* (1-30 characters) identifies the namespace.

*vol-path* (1-1024 characters) is the name of the volume.

*snapshot-rule* (1-1024 characters) is the snapshot rule to invoke.

*snapshot-instance* (optional; 1-68 characters) specifies a name for the snapshot. If you omit this, the name defaults to “*snapshot-rule\_0*” (for example, “nightly\_0” for a snapshot rule named “nightly”). You cannot choose the name of an existing snapshot.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation after you enter this command. Enter **yes** to proceed.

This is not generally recommended for a scheduled [snapshot rule](#), except to replace a scheduled snapshot that failed. If the rule has reached its maximum [retain](#) count, this deletes the oldest snapshot after creating the new one. A manual snapshot also disrupts the continuity of the snapshot schedule: for example, a Tuesday-morning snapshot may not be useful in a rule that takes weekly snapshots every Sunday night. Use [show global-config namespace namespace volume](#) to determine whether or not the rule has a schedule.

This command makes a snapshot-create report to show the configuration and progress of the snapshot operation. The name of the report appears on the command line after you confirm the command. See [Figure 30.1 on page 30-9](#) for a sample snapshot-create report.

This command creates filer snapshots asynchronously, allowing you to continue entering CLI commands while the operation proceeds. You can use the [tail reports report-name follow](#) command to follow the progress of the snapshot creation. You can also use [wait-for snapshot create](#) to wait for all snapshots to finish on the back-end filers; this is especially useful in CLI scripts.

Some filers may remove their snapshots to conserve space. To verify that all filer snapshots are still available behind a snapshot rule, use the [snapshot verify](#) command. To remove filer snapshots from behind a snapshot rule yourself, use [snapshot remove](#).

**Sample** prtlnDA# `snapshot create nemed /vol144 COB`

Snapshot rule 'COB' in namespace 'nemed' volume '/vol144' has a schedule associated with it. Running this rule may cause existing snapshots to be removed if the retain count is exceeded by this request.  
Proceed? [yes/no] **yes**

Starting snapshot operation in volume /vol144, report name:  
snap\_cob\_0\_create\_200707180325.rpt

invokes the “COB” rule and creates a snapshot of the “nemed~/vol144” volume.

**Related Commands** [snapshot rule](#)  
[schedule \(gbl-ns-vol-...snap\)](#)  
[retain](#)  
[wait-for snapshot create](#)  
[snapshot verify](#)  
[snapshot remove](#)

---

## snapshot directory cifs-name

**Purpose** An ARX volume can periodically take *snapshots*, or point-in-time copies, of all of its contents. CIFS administrators can access the volume's snapshots through hidden pseudo directories, called "~snapshot" by default. This directory exists under every directory in the volume. Use the `snapshot directory cifs-name` command to rename this directory for CIFS clients.

Use `no snapshot directory cifs-name` to return to the default name for the container directory.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `snapshot directory cifs-name container-directory`  
`no snapshot directory cifs-name`

*container-directory* (1-32 characters) is the CIFS name you choose for the pseudo directory that contains snapshots. This directory exists under every directory in the volume. Do not use any characters that are illegal in CIFS names: the illegal characters are any control character, /, \, :, \*, >, <, ", |, or ?. Also, avoid any name that a client might use for a standard file or directory.

**Default(s)** ~snapshot

**Guidelines** The snapshot directory exists under every directory in the volume, but does not appear by default. For example, if drive "M:" maps to an ARX volume with snapshots and has two subdirectories, lab1 and lab2, all of the following snapshot directories exist: M:\~snapshot, M:\lab1\~snapshot, and M:\lab2\~snapshot. The ~snapshot directory does not appear when you type `dir` in M:\lab1, or in the Windows Explorer view of that directory, but a well-informed client can access it by name (for example, by entering `cd M:\lab1\~snapshot` in a DOS shell). You can use this command to change the name of the ~snapshot directory in all directories of the volume.

This is the name of the directory as seen by CIFS clients, not NFS clients. To control the directory name seen by NFS clients, use the [snapshot directory nfs-name](#) command.

To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the [snapshot rule](#) command.

The [snapshot privileged-access](#) command makes snapshots accessible only to a privileged group of CIFS clients that you can create on the ARX. This applies to the snapshot directory as well as access through Properties -> Previous Versions in Windows Explorer. If this is set, clients without privileges can not enter or read any snapshot directories in the volume. If this is disabled, all clients can access the snapshot directories as long as they are aware of the directory name.

You can use the [snapshot directory display](#) command to control the volume exports that display this directory. You can choose to display the special directory only in exports of the volume-root directory, in exports of any directory in the volume, or in no exports of the volume.

**Samples** `bstnA(gbl-ns-vol[access~/G])# snapshot directory cifs-name ~ckpt`  
creates a sub directory named “~ckpt” under every directory in the “access~/G” volume. CIFS clients can access any directory’s snapshots from the directory’s “~ckpt” subdirectory.

`bstnA(gbl-ns-vol[medarcv~/lab_equipment])# no snapshot directory cifs-name`  
reverts to the default snapshot-directory name (as seen through CIFS) in the “medarcv~/lab\_equipment” volume.

**Related Commands** [snapshot rule](#)  
[snapshot directory nfs-name](#)  
[snapshot privileged-access](#)  
[snapshot directory display](#)

---

# snapshot directory display

**Purpose** A well-informed client can access a volume's *snapshots*, or point-in-time copies, through an undisplayed pseudo directory. The client must know the name of the pseudo directory (typically “~snapshot” for CIFS and “.snapshot” for NFS) to access it; the name does not appear in directory listings. You can use the `snapshot directory display` command to display the pseudo directory in all of the volume's front-end exports. You can also use this command to limit the display to exports of the volume's root directory, so that exports of lower-level directories do not display “~snapshot.”

Use `no snapshot directory display` to stop displaying the snapshot directory in any export of the volume. With this setting, clients need to know the name of the directory to `cd` to it.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `snapshot directory display {all-exports | volume-root-only} [hidden]`

`no snapshot directory display`

**all-exports | volume-root-only** is a required choice. This selects the type of front-end export that displays the `~snapshot/.snapshot` directory:

**all-exports** means to display the special directory in the root of any front-end export. For example, the `/users` volume would display the snapshot directory in an export of `/users/jsmith` or in an export of the volume root (`/users`).

**volume-root-only** displays the `~snapshot/.snapshot` directory only in front-end exports of the volume root (`/users` in the previous example), not in exports of a lower-level directory (such as `/users/tjefferson`). This is useful for a site where most clients use exports below the volume root, and only administrators use an export at the root.

**hidden** raises the DOS “hidden” attribute for the `~snapshot` directory. This limits the display to CIFS clients that are configured to override the “hidden” attribute. It has no effect on NFS clients.

**Default(s)** `no snapshot directory display`

**Guidelines** For CIFS clients, this command is often used in conjunction with the `no snapshot vss-mode` command, which stops snapshot access through the VSS interface. VSS (or Volume Shadowing Service) allows Windows clients to click on a file or directory in Windows Explorer, pull up the **Properties** pop-up, and access snapshots for the file or directory through the **Previous Versions** tab. This intuitive interface is designed for the vast majority of CIFS clients, whereas the `~snapshot` directory is designed for well-informed CIFS administrators.

Direct volumes and NFS-only volumes do not support VSS, so the `~snapshot/.snapshot` directory is the only means of snapshot access for direct-volume clients and NFS clients.

**Guidelines (Cont.)** Administrative clients can access the pseudo directory whether or not you display it with this command; for example, a Windows administrator can use **cd M:\users\~snapshot** in a DOS shell to enter the ~snapshot directory under \users, or a Unix administrator can use **cd /home/.snapshot**. You can use the [snapshot directory cifs-name](#) command to change the directory name seen by CIFS clients, and you can use [snapshot directory nfs-name](#) to change the NFS name. If the volume uses [snapshot privileged-access](#), only privileged CIFS clients can access the volume's snapshots, either through VSS or through the ~snapshot directory. (The [snapshot privileged-access](#) command has no effect on NFS clients.)

This change is visible to CIFS clients the next time they issue the **dir** command, or on the next refresh of their graphical view. For NFS clients, the directory appears on the next **ls** command. That is, the snapshot directory seems either appear or vanish from the volume's front-end exports.

To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the [snapshot rule](#) command.

**Samples** `bstnA(gbl-ns-vol[medarcv~/lab_equipment])# snapshot directory display all-exports`

shows the snapshot-container directory in all exports of the "medarcv~/lab\_equipment" volume.

`bstnA(gbl-ns-vol[access~/G])# no snapshot directory display`  
stops the display of the snapshot-container directory in exports of "access~/G."

# snapshot directory nfs-name

**Purpose** An ARX volume can periodically take *snapshots*, or point-in-time copies, of all of its contents. NFS clients can access the volume's snapshots through hidden pseudo directories, called ".snapshot" by default. This directory exists under every directory in the volume. Use the `snapshot directory nfs-name` command to rename this directory for NFS clients.

Use `no snapshot directory nfs-name` to return to the default name for the container directory.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `snapshot directory nfs-name container-directory`  
`no snapshot directory nfs-name`

*container-directory* (1-32 characters) is the NFS name you choose for the pseudo directory that contains snapshots. This directory exists under every directory in the volume. Avoid any name that a client might use for a standard file or directory.

**Default(s)** .snapshot

**Guidelines** The snapshot directory exists under every directory in the volume, but does not appear by default. For example, if the directory "/mnt/arx" is mounted to an ARX volume with snapshots and has two subdirectories, lab1 and lab2, all of the following snapshot directories exist: /mnt/.snapshot, /mnt/lab1/.snapshot, and /mnt/lab2/.snapshot. The .snapshot directory does not appear when you type `ls` in /mnt/lab1, but a well-informed client can access it by name (for example, by entering `cd /mnt/lab1/.snapshot` in a Unix shell). You can use this command to change the name of the .snapshot directory in all directories of the volume.

This is the name of the directory as seen by NFS clients, not CIFS clients. To control the directory name seen by CIFS clients, use the [snapshot directory cifs-name](#) command.

To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the [snapshot rule](#) command.

You can use the [snapshot directory display](#) command to control the volume exports that display this directory. You can choose to display the special directory only in exports of the volume-root directory, in exports of any directory in the volume, or in no exports of the volume.

**Sample** `bstnA(gbl-ns-vol[access~/G])# snapshot directory nfs-name .ckpt`  
 creates a directory name of ".ckpt" under every directory in the "access~/G" volume. NFS clients can access their snapshots from any instance of the ".ckpt" directory.

[snapshot directory cifs-name](#)  
[snapshot privileged-access](#)  
[snapshot directory display](#)

## snapshot manage

**Purpose** Use the `snapshot manage` command to incorporate a filer snapshot into an ARX snapshot.

**Modes** `priv-exec`

**Security Role(s)** `backup-operator`, `storage-engineer`, or `crypto-officer`

**Syntax** `snapshot manage namespace vol-path share rule filer-snap  
created-on date-time [report-prefix prefix] [verbose]`

*namespace* (1-30 characters) identifies the ARX namespace.

*vol-path* (1-1024 characters) is the name of the ARX volume.

*share* (1-64 characters) is the name of the ARX share.

*rule* (1-1024 characters) is the snapshot rule to receive the filer snapshot.

*filer-snap* (1-255 characters) identifies the snapshot to incorporate from the back-end filer.

*date-time* is the date and time that the ARX snapshot was created, in `mm/dd/yyyy:HH:MM:SS` format. This identifies the specific ARX snapshot to include the *filer-snap*. You can find this in the output of `show snapshots`. If you enter a time when no snapshot was previously taken, this creates a new ARX snapshot.

*prefix* (optional, 1-64 characters) is the prefix for a report file. The CLI logs its output to a report file named as follows:

`prefix-namespace-volume-rule-yyyymmddHHMM.rpt`

where *prefix*, *namespace*, *volume*, and *rule* are all chosen in this command, and `yyyymmddHHMM` is the current date and time.

**verbose** (optional) forces a report even for a successful operation; by default, the command only produces a report if there is an error.

**Default(s)** *prefix* - "snapshot-manage"

**Guidelines** This command incorporates the snapshot synchronously, before returning to the next CLI prompt. If the snapshot fails, or if you entered the **verbose** keyword, a report name appears. You can use `show reports report-name` to view the report's contents.

You can use the `snapshot clear` command to clear one or more snapshots from the ARX configuration. The `snapshot clear` command disconnects back-end snapshots from the ARX configuration, but does not remove any snapshot rules or back-end snapshots.

Use the `snapshot rule` command to create a snapshot rule for the ARX volume. The snapshot rule is required for incorporating an existing snapshot; it defines the schedule for creating future snapshots (if any) and the number of snapshots to retain.

**Sample** `prt1ndA# snapshot manage nemed /vol17 vol2exp daily daily.0 created-on  
2008/06/05:01:04:54`  
incorporates an existing filer snapshot, "daily.0," into the "nemed~/vol17" volume.

| <b>Syntax</b>                                      | <code>snapshot privileged-access</code><br><code>no snapshot privileged-access</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default(s)</b>                                  | <code>no snapshot privileged-access</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Guidelines</b>                                  | <p>This command has no effect on NFS clients.</p> <p>You can use this command to select a privileged set of CIFS clients with access to snapshots. CIFS clients outside the namespace's WMA group(s) cannot access the volume's snapshots by any method.</p> <p>The <code>no</code> form of this command opens up snapshot access to all CIFS clients.</p> <p>Use the <code>windows-mgmt-auth</code> command to create a WMA group, <code>permit snapshot monitor</code> (<code>permit (gbl-mgmt-auth)</code>) to authorize the group for snapshot access, and <code>windows-mgmt-auth (gbl-ns)</code> to assign the WMA group to the current namespace. If no such WMA groups are assigned to the namespace, this command disables snapshot access for all clients.</p> <p>To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the <code>snapshot rule</code> command.</p> |
| <b>Guidelines: Methods for Accessing Snapshots</b> | <p>CIFS clients have two methods for accessing snapshots. The most intuitive method is through the Windows Explorer interface: select a desired file or directory, pull up <b>Properties</b>, and click the <b>Previous Versions</b> tab. This is called the Microsoft Volume-Shadowing Service (<i>VSS</i>) interface. The second method is designed primarily for CIFS administrators: access snapshots through a pseudo directory named <code>~snapshot</code>, which is not displayed by default. This is the only interface supported by direct volumes, and it is the only way NFS clients can access their snapshots. (For NFS clients, the directory name is <code>“.snapshot”</code>.)</p>                                                                                                                                                                                                                                                                           |

**Guidelines:  
Alternatives for  
Controlling Snapshot  
Access**

If snapshot privileged-access is enabled, CIFS clients within the right WMA group(s) can access snapshots. If not, all CIFS clients can access snapshots. In either case, clients with snapshot access are subject to restrictions from these commands:

- You can use `no snapshot vss-mode` to stop all snapshot access through VSS. This only applies to CIFS clients.
- You can `snapshot directory display` to control the visibility of the `~snapshot/.snapshot` directory. By default, the volume does not display the directory; well-informed CIFS or NFS clients must enter its exact path to access its snapshots.
- You can use the `snapshot directory cifs-name` command to change the name of the snapshot-container directory, as seen by CIFS clients. You can also use `snapshot directory nfs-name` to change the name seen by NFS clients.

If this command, `snapshot privileged-access`, is enabled, no CIFS client *outside* the namespace's WMA groups can access snapshots at all. As mentioned above, this command has no effect on NFS clients.

**Samples**

```
bstnA(gbl-ns-vol[medarcv~/lab_equipment])# snapshot privileged-access
 makes snapshots in "medarcv~/lab_equipment" accessible to only a small group
 of CIFS clients: the properly-authorized members of the namespace's WMA
 group(s).
```

```
bstnA(gbl-ns-vol[access~/G])# no snapshot privileged-access
 ignores WMA groups in the "access~/G" volume.
```

[snapshot directory display](#)  
[snapshot directory cifs-name](#)  
[snapshot directory nfs-name](#)  
[export \(gbl-cifs\)](#)

## snapshot remove

**Purpose** An ARX volume creates *snapshots*, or point-in-time copies, by coordinating snapshots and/or checkpoints at its back-end filers. A [snapshot rule](#) establishes the name of the ARX snapshots, the number of snapshots to retain under that name, and an optional schedule for taking snapshots. You can use the `snapshot remove` command to remove the filer snapshots behind a snapshot rule, without removing the rule itself.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer`, `backup-operator`, or `crypto-officer`

**Syntax** `snapshot remove namespace vol-path snapshot-rule [snapshot-instance]`

*namespace* (1-30 characters) identifies the namespace.

*vol-path* (1-1024 characters) is the name of the volume.

*snapshot-rule* (1-1024 characters) is the snapshot rule.

*snapshot-instance* (optional, 1-68) identifies a particular snapshot created by the snapshot rule.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before removing any snapshots from any filers. Enter `yes` to continue.

This command produces a separate removal report for each ARX snapshot. Each report shows the configuration of the snapshot rule, a summary status for the each ARX snapshot, and removal details about the filer snapshots for each ARX snapshot. See [Figure 30.5 on page 30-54](#) for a sample removal report.

To remove the rule configuration itself, use the `no snapshot rule` command. If you want to remove the snapshot rule without leaving any of its filer snapshots behind, use this command first.

This command removes filer snapshots asynchronously, allowing you to continue entering CLI commands while the operation proceeds. You can use the `tail reports report-name follow` command to follow the progress of each snapshot removal. You can also use [wait-for snapshot remove](#) to wait for all snapshot removals to finish; this is especially useful in CLI scripts.

You can use the [snapshot create](#) command to manually create a new snapshot behind an existing snapshot rule.

---

**Sample** bstnA# `snapshot remove medarcv /lab_equipment hourlySnap`

Confirmation of this command results in the removal all snapshots associated with snapshot rule 'hourlySnap' in namespace 'medarcv' volume '/lab\_equipment'. The snapshot rule is not deleted.

Proceed? [yes/no] **yes**

Starting snapshot operation in volume /lab\_equipment, report name: snap\_hourly\_0\_remove\_20120229040753550.rpt

---

## snapshot replica-snap-rule

**Purpose** A *snapshot* is a copy of all files and directories in an ARX volume at a particular point in time. A standard [snapshot rule](#) determines the schedule for taking snapshots and the number snapshots to retain; these snapshots reside on the same back-end shares that store the volume's files. A *replica-snap rule* takes snapshots only on special [replica-snap](#) shares behind the volume. A filer-replication program (such as SnapMirror or RoboCopy) replicates a primary share to the replica-snap share regularly and independently. The server with the replica-snap share is presumed to have enough disk space for a large number of snapshots. You can use a replica-snap rule to take regular snapshots on the replica-snap share(s). This eases the storage burden on the filer behind the primary share(s). Use this command, `snapshot replica-snap-rule`, to start configuring a replica-snap rule.

Use the `no` form of the command to remove the replica-snap rule without removing any of the snapshots behind it.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `snapshot replica-snap-rule name`  
`no snapshot replica-snap-rule name`

*name* (1-1024 characters) is a name you choose for the replica-snap rule.

**Default(s)** None

**Guidelines: Filer Preparation** Before you begin, you must prepare the filers behind the volume. The volume must have one or more [replica-snap](#) shares, where each replica-snap share is backed by NetApp filers, EMC Celerra servers, EMC Data Domain systems, and/or Windows servers that support snapshots. In the case of Windows servers, WinRM must also be installed so that the ARX can invoke snapshots through its management API.

Each replica-snap share holds an updated duplicate of the files and directories in another share. The source share and the replica-snap share are both in the same managed volume. The managed volume presents the source share's files and directories to its clients, along with any snapshots in the replica-snap share. It may also present the source share's snapshots if you configure a standard [snapshot rule](#) for the volume.

The ARX volume creates a coordinated snapshot by issuing CLI commands to the back-end filer(s) that host its replica-snap shares. The ARX therefore needs information and credentials for accessing each filer's CLI. From `gbl-filer` mode, use the `filer-type` command to identify the filer vendor, use `proxy-user (gbl-filer)` to identify a proxy user with proper management-login credentials, and use `manage snapshots` to declare that the filer supports snapshots. You can use the `ip address ... management` command to designate the management-IP address at that station (by default, the ARX logs into the CLI through an external filer's primary-IP address, set with the simplest syntax for the `ip address` command).

**Guidelines: Some  
Filer-Replication  
Applications  
Overwrite ARX  
Snapshots**

Some filer-replication applications are volume-level, and copy the entire contents of the back-end share to the replica-snap share, including the filer snapshots. This would overwrite any snapshots that the ARX takes at the replica-snap share, and defeat the purpose of this rule. Do not use volume-level replication to copy the source share's contents to the replica-snap share.

**Guidelines**

An enabled replica-snap rule is the basis for managing replica snapshots on the ARX. You can apply a schedule to the rule so that it takes regular snapshots, or you can invoke the rule manually with the [snapshot create](#) command. This type of rule only creates snapshots on [replica-snap](#) shares, and ignores standard shares; use the [snapshot rule](#) command to create snapshots on standard shares, too.

When you create a new replica-snap rule, the CLI prompts for confirmation. Enter **yes** to create the rule. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.)

This command places you in `gbl-ns-vol-replica-snap` mode, where you enable the rule and where you have some options that you can apply to it. By default, a replica-snap rule retains three snapshots; whenever it successfully creates a new snapshot, it deletes the oldest snapshot so that there are never more than three. You can use the optional [retain](#) command to change the number of retained snapshots; a high retention count is typical for a replica-snap rule, since it only takes disk space on the replica-snap shares. You can set a regular schedule for the replica snapshots with the [schedule \(gbl-ns-vol-...snap\)](#) command; we recommend a different schedule from the one used for the volume's standard snapshots. To enable report-generation for each snapshot, use the [report \(gbl-ns-vol-...snap\)](#) command. You must use the [enable \(gbl-ns-vol-...snap\)](#) command enable this rule to take any snapshots at all, even manually.

A replica-snap rule has no effect in a direct volume, which cannot contain any replica-snap shares.

You can use [snapshot manage](#) to incorporate existing filer snapshots from the replica-snap shares into the replica-snap rule.

Each ARX snapshot has one or more component snapshots on its back-end filers. You can use the [snapshot verify](#) command to verify that all of the component snapshots still exist behind a replica-snap rule.

To see the current state of snapshots, including replica snapshots, use the [show snapshots](#) command.

**Guidelines: Snapshot Presentation to Clients**

By default, CIFS clients can access their snapshots with Windows Explorer. They select a file or directory, pull up its **Properties**, and find a list of snapshots for the file or directory in the **Previous Versions** tab. CIFS clients can use this interface to find and restore previous versions of their files and directories. Microsoft calls this the Volume Shadowing Service, or *VSS*, for Shared Folders. Managed volumes support VSS for Shared Folders, but direct volumes do not and NFS clients do not use VSS.

**◆ Note**

*If CIFS clients were connected to the volume before you create your first snapshot-related rule (snapshot rule, notification rule, or this rule), the clients must shut down and restart all instances of Windows Explorer before they can see the Previous Versions tab. Windows Explorer only checks for snapshot support when it first connects to the share.*

The snapshots from a replica-snap rule appear interleaved with any snapshots from a standard [snapshot rule](#).

Some filer-replication applications may drop file attributes, such as Windows Security Descriptors. If this occurs, the replica snapshots do not include these attributes. The managed-volume software cannot detect or correct this issue.

For installations where only administrators are allowed to access snapshots, you have commands for controlling VSS access:

- You can use [snapshot privileged-access](#) to select a limited number of CIFS clients (the site administrators) who can access snapshots.
- You can also (or alternatively) stop VSS access altogether with no [snapshot vss-mode](#). Administrators can continue to access snapshots through a special pseudo directory, `~snapshot`, that is not displayed by default.

Both of the above options affect CIFS clients only; they have no effect on NFS clients.

You can use [snapshot directory cifs-name](#) to change the name of the `~snapshot` directory. This is the name seen by CIFS clients only; you can use [snapshot directory nfs-name](#) to provide a different name for NFS clients. You can also control the display of the directory based on the export: use the [snapshot directory display volume-root-only](#) command to display this directory only in exports from the root of the volume, not in exports of the volume's subdirectories. These commands affect NFS clients as well as CIFS clients.

**Guidelines: Data Domain Servers and Presentation Through NFS**

EMC Data Domain servers provide a unique presentation to NFS clients; they are only accessible from volume root's `.snapshot` directory. The `.snapshot` directory under each lower directory may or may not include the Data Domain snapshots.

This limitation does not apply to CIFS clients, who can access the Data-Domain snapshots in every `~snapshot` directory.

**Guidelines:** Each EMC or NetApp snapshot has a unique name to distinguish it as a backing snapshot for a particular ARX. The snapshot names use the following format

**Filer-Snapshot Names**

`acopia_id_time-stamp_uuid_filer-volume`

where

- *id* is an integer that the snapshot software uses internally.
- *time-stamp* is in `yyyymmddHHMM` format. This is the time that the snapshot was created.
- *uuid* is the Universally-Unique ID that identifies the ARX. In a redundant pair, this is the UUID for the peer that was originally configured as senior/active, no matter which peer is currently active. You can find an ARX's UUID in the output of [show running-config](#).
- *filer-volume* is the name of the filer's volume.

Windows servers use a UUID in curly braces ({} ) to identify each snapshot. This does not change for ARX-generated snapshots.

**Guidelines:**  
**Configuration**  
**Changes in a**  
**Scheduled Rule**

If you make a configuration change in a replica-snap rule that is running with a schedule, the configuration change is ineffective until the next time the rule runs.

**Guidelines: Removing**  
**the Replica-Snap Rule**

The `no` form of the command removes the replica-snap rule without removing any snapshots from the back-end filers. To remove the snapshots from the filers, use the [snapshot remove](#) command *before* you remove the rule. This is an efficient method for cleaning all of the supporting snapshots behind the rule. If supporting snapshots remain when you invoke `no snapshot replica-snap-rule`, the CLI lists all remaining snapshots when it prompts for confirmation.

**Guidelines: Snapshot**  
**Reconstitution**

An accidental replica-snap-rule removal would separate the back-end snapshots from the ARX configuration, requiring a *reconstitution* of the coordinated snapshot. There are other situations where you may require snapshot reconstitution, too, such as a site-to-site failover: if a filer mechanism duplicates all of the filer snapshots from Site A over to Site B, and each site is managed by its own ARX pair, the snapshots at Site B need to be reconstituted in Site B's ARX pair (see [cluster-name](#) and [activate configs](#) for details about site-to-site failovers). The snapshot-reconstitution process requires some preparation when you start adding snapshot and replica-snap rules to the configuration. These guidelines show the high-level process for preparing your snapshots, along with the process for reconstituting snapshots in the event of an issue.

**Guidelines: Preparing for Snapshot Reconstitution**

After you add your first snapshot or replica-snap rule, choose an external repository to hold all of the latest snapshot reports. Choose a filer with a large amount of free space, or monitor the filer's space frequently and remove outdated snapshot reports. Every snapshot report has a timestamp in its name, so it is unique.

The filer should be able to run Perl scripts, and requires the XML::Simple module. You can download this Perl module from CPAN (<http://search.cpan.org>) if your system does not already have it.

Use the `at` command together with `copy ftp`, `copy scp`, `copy {nfs|cifs}`, or `copy smtp` to regularly copy snapshot reports from the ARX to your chosen filer. Use the common string for all of your snapshot reports, together with an "\*" or other wildcard. The report repository should always hold the latest snapshot reports, so that they have the latest back-end snapshot names. For example, this command copies all reports starting with "snap" to an external IP each morning:

```
bstnA(cfg)# at 01:19:18 every 1 day do "copy reports snap*
ftp://ftpuser:ftpuser@172.16.100.183//var/arxSnapRpts/ format xml"
```

The scheduled execution time for CLI command is: 3/30/09 1:19 AM.

You also need a copy of the "snap-recon.pl" script from the "software" directory on the ARX:

```
bstnA# copy software snap-recon.pl
ftp://ftpuser:ftpuser@172.16.100.183//var/arxSnapRpts/
```

**Guidelines: Reconstituting ARX Snapshots**

You can perform snapshot reconstitution if you have the snap-recon.pl script and the latest set of snapshot reports on a host that supports Perl. Start by running the snap-recon.pl script on that host. This produces a CLI script with a sequence of [snapshot manage](#) commands. By default, the output script is named, "snapRecon.cli." This script has several options; execute the command without any options to get a complete list. You must use the "--report-dir *directory*" option to specify the *directory* that holds the reports. For example, this command sequence lists the files on "client2:/var/arxSnapRpts," runs snap-recon.pl on the reports in the current directory (.), and then shows the new file in the directory:

```
juser@client2:/var/arxSnapRpts$ ls
snap_daily_0_create_20090330010418883.xml snap_hourly_0_create_20090330010652616.xml
snap_daily_0_create_20090330010454303.xml snap_hourly_0_create_20090330010723024.xml
snap_daily_0_create_20090330010524663.xml snap-recon.pl
snap_daily_2_remove_20090330010612220.xml
juser@client2:/var/arxSnapRpts$./snap-recon.pl --report-dir .
juser@client2:/var/arxSnapRpts$ ls
snap_daily_0_create_20090330010418883.xml snap_hourly_0_create_20090330010652616.xml
snap_daily_0_create_20090330010454303.xml snap_hourly_0_create_20090330010723024.xml
snap_daily_0_create_20090330010524663.xml snapRecon.cli
snap_daily_2_remove_20090330010612220.xml snap-recon.pl
juser@client2:/var/arxSnapRpts$
```

**Guidelines:**  
**Reconstituting ARX**  
**Snapshots (Cont.)**

You have the option to edit the CLI script before you run it on the ARX. For example, the ARX volumes at a disaster-recovery site may have different names than those at the primary site. The `snapRecon.cli` script has several options for substituting these names; you can use these to rebuild the CLI script, or you can manually edit the CLI script.

Once the CLI script is ready, you can download it to the ARX and run it. Use `copy ftp`, `copy {nfs|cifs}`, or `copy scp` for the download, and use `run` to run it.

A large, complex CLI script may contain errors. If you discover any back-end snapshots that are mismatched with their ARX counterparts, you can use the `snapshot clear` command to remove the ARX snapshot (not the rule) from the configuration. Then you can edit and re-run the script, or you can use `snapshot manage` to manually incorporate the back-end snapshots into the correct ARX snapshots.

**Samples**

```
bstnA(gbl-ns-vol[access~/G])# snapshot rule nightly
This will create a new policy object.
```

```
Create object 'nightly'? [yes/no] yes
bstnA(gbl-ns-vol-snap[access~/G~nightly])# ...
instantiates a new snapshot rule, "nightly," in the current namespace volume.
```

```
bstnA(gbl-ns-vol[medarcv~/lab_equipment])# no snapshot rule hourlySnap
```

The following snapshots are being managed by the rule 'hourlySnap':

```
hourlySnap_0(acopia_27_200707170500_501f705c-8735-11d8-8936-a58a9e4556
df_datavol2)
```

```
hourlySnap_2(acopia_25_200707170300_501f705c-8735-11d8-8936-a58a9e4556
df_datavol2)
```

```
hourlySnap_1(acopia_26_200707170400_501f705c-8735-11d8-8936-a58a9e4556
df_datavol2)
```

If this command is confirmed, the rule is deleted and all associated data related to the aforementioned snapshots will be removed from the switch. The snapshots on the filers will not be removed.

```
Proceed? [yes/no] yes
bstnA(gbl-ns-vol-snap[medarcv~/lab_equipment])# ...
removes a snapshot rule with some existing snapshots remaining on one of its
back-end filers.
```

## snapshot rule

**Purpose** A *snapshot* is a copy of all files and directories in an ARX volume at a particular point in time. A snapshot rule determines the schedule for regular snapshots (if any) and the number snapshots to retain. Use this command to start configuring a snapshot rule.

Use the **no** form of the command to remove the snapshot rule without removing any of the snapshots behind it.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **snapshot rule** *name*  
**no snapshot rule** *name*

*name* (1-1024 characters) is a name you choose for the snapshot rule.

**Default(s)** None

**Guidelines: Filer Preparation** Before you begin, you must prepare the filers behind the volume. The volume must be backed by NetApp filers, EMC Celerra servers, EMC Data Domain systems, and/or Windows servers that support snapshots. In the case of Windows servers, WinRM must also be installed so that the ARX can invoke snapshots through its management API.

The ARX volume creates a coordinated snapshot by issuing CLI commands to each of its back-end filers. The ARX therefore needs information and credentials for accessing each filer's CLI. From gbl-filer mode, use the **filer-type** command to identify the filer vendor, use **proxy-user (gbl-filer)** to identify a proxy user with proper management-login credentials, and use **manage snapshots** to declare that the filer supports snapshots. You can use the **ip address ... management** command to designate the management-IP address at that station (by default, the ARX logs into the CLI through an external filer's primary-IP address, set with the simplest syntax for the **ip address** command).

---

**Guidelines** An enabled snapshot rule is the basis for managing snapshots on the ARX. You can apply a schedule to the rule so that it takes regular snapshots, or you can invoke the rule manually with the [snapshot create](#) command.

When you create a new snapshot rule, the CLI prompts for confirmation. Enter **yes** to create the rule. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.)

This command places you in `gbl-ns-vol-snap` mode, where you enable the rule and where you have some options that you can apply to it. By default, a snapshot rule retains three snapshots; whenever it successfully creates a new snapshot, it deletes the oldest snapshot so that there are never more than three. You can use the optional [retain](#) command to change the number of retained snapshots. You can set a regular schedule for the snapshots with the [schedule \(gbl-ns-vol-...snap\)](#) command. To enable report-generation for each snapshot, use the [report \(gbl-ns-vol-...snap\)](#) command. You must use the [enable \(gbl-ns-vol-...snap\)](#) command enable this rule to take any snapshots at all, even manually. To exclude one of the volume's shares from the coordinated snapshot (under the advisement of F5 Support), you can use the [exclude](#) command.

You can configure a snapshot rule in a managed volume or a direct volume. The snapshot rule does not require any metadata, so a direct volume can support it.

You can use [snapshot manage](#) to incorporate existing filer snapshots into the snapshot rule.

Each ARX snapshot has one or more component snapshots on its back-end filers. You can use the [snapshot verify](#) command to verify that all of the component snapshots still exist behind a snapshot rule.

To see the current state of snapshots, use the [show snapshots](#) command.

**Guidelines:  
Coexistence with  
Replica-Snap Rules**

If your back-end file servers replicate one or more of your tier-1 shares on a cheaper server, where you create and store a growing collection of snapshots, you can declare that server's shares as special [replica-snap](#) shares. A [snapshot replica-snap-rule](#) makes coordinated snapshots of all replica-snap shares in the current volume, and a [snapshot rule](#) (described here) makes coordinated snapshots of all the other shares in the current volume. ARX clients see the snapshots from a [replica-snap rule](#) interleaved with the snapshots from a standard [snapshot rule](#).

**Guidelines: VIP  
Fencing**

During a snapshot-create operation, clients can access the volume and possibly make changes, rendering the filer snapshots inconsistent from one another. For most sites, this inconsistency is rarely an issue. For sites where consistency is important, you can use the [snapshot consistency](#) command to put up a *VIP fence* for snapshots. This fence prevents client access to any VIP that supports this volume. This may affect multiple volumes. The fence stays up until the last filer completes its snapshot or checkpoint, or until a timeout expires.

**Guidelines: Snapshot  
Presentation to  
Clients**

By default, CIFS clients can access their snapshots with Windows Explorer. They select a file or directory, pull up its **Properties**, and find a list of snapshots for the file or directory in the **Previous Versions** tab. CIFS clients can use this interface to find and restore previous versions of their files and directories. Microsoft calls this the Volume Shadowing Service, or **VSS**, for Shared Folders. Managed volumes support VSS for Shared Folders, but direct volumes and NFS-only volumes do not.

◆ **Note**

---

*If CIFS clients were connected to the volume before you create your first snapshot-related rule (**snapshot replica-snap-rule**, **notification rule**, or **this rule**), the clients must shut down and restart all instances of Windows Explorer before they can see the **Previous Versions** tab. Windows Explorer only checks for snapshot support when it first connects to the share.*

For installations where administrators are the only CIFS clients allowed to access snapshots, you have commands for controlling VSS access:

- You can use **snapshot privileged-access** to select a limited number of CIFS clients (the site administrators) who can access snapshots.
- You can also (or alternatively) stop VSS access altogether with **no snapshot vss-mode**. Administrators can continue to access snapshots through a special pseudo directory, **~snapshot**, that is not displayed by default.

Both of the above options affect CIFS clients only; they have no effect on NFS clients.

You can use **snapshot directory cifs-name** to change the name of the **~snapshot** directory that CIFS clients see. To change the directory name seen by NFS clients, use **snapshot directory nfs-name**. You can also control the display of the directory based on the export: use the **snapshot directory display volume-root-only** command to display this directory only in ARX exports from the root of the volume, not in exports of the volume's subdirectories. These commands apply to NFS clients as well as CIFS clients.

Clients only see the snapshots that were invoked by the ARX rule or added to the rule with **snapshot manage**. Snapshots made independently on the back-end filer are not shown.

**Guidelines: Data  
Domain Servers and  
Presentation Through  
NFS**

EMC Data Domain servers provide a unique presentation to NFS clients; they are only accessible from volume root's **.snapshot** directory. The **.snapshot** directory under each lower directory does not include the Data Domain snapshots.

This limitation does not apply to CIFS clients, who can access the Data-Domain snapshots in every **~snapshot** directory.

You can avoid this NFS limitation if every directory on the Data Domain server(s) is striped to another filer type. To ensure universal striping, migrate all directories in the volume to a share from a different vendor and promote them to "master:"

- create a **filename-fileset** that recursively matches everything in the volume (using **path exact /** and **recurse**),
- create a **place-rule**, and
- use the **from (gbl-ns-vol-plc)** command to have that fileset match directories and promote them.

In a tiered volume, you can use this place rule to migrate all master directories to a Tier 1 share. This is a best practice for tiered volumes.

---

**Guidelines:** Each EMC or NetApp snapshot has a unique name to distinguish it as a backing snapshot for a particular ARX. The snapshot names use the following format

**Filer-Snapshot Names** `acopia_id_time-stamp_uuid_filer-volume`

where

- *id* is an integer that the snapshot software uses internally.
- *time-stamp* is in `yyyymmddHHMM` format. This is the time that the snapshot was created.
- *uuid* is the Universally-Unique ID that identifies the ARX. In a redundant pair, this is the UUID for the peer that was originally configured as senior/active, no matter which peer is currently active. You can find an ARX's UUID in the output of [show running-config](#).
- *filer-volume* is the name of the filer's volume.

Windows servers use a UUID in curly braces ({} ) to identify each snapshot. This does not change for ARX-generated snapshots.

**Guidelines:** If you make a configuration change in a snapshot rule that is running with a schedule, the configuration change is ineffective until the next time the rule runs.

**Configuration Changes in a Scheduled Rule**

**Guidelines: Removing the Snapshot Rule** The `no` form of the command removes the rule without removing any snapshots from the back-end filers. To remove the snapshots from the filers, use the [snapshot remove](#) command *before* you remove the rule. This is an efficient method for cleaning all of the supporting snapshots behind the rule. If supporting snapshots remain when you invoke `no snapshot rule`, the CLI lists all remaining snapshots when it prompts for confirmation.

**Guidelines: Snapshot Reconstitution** An accidental snapshot-rule removal would separate the back-end snapshots from the ARX configuration, requiring a *reconstitution* of the coordinated snapshot. There are other situations where you may require snapshot reconstitution, too, such as a site-to-site failover: if a filer mechanism duplicates all of the filer snapshots from Site A over to Site B, and each site is managed by its own ARX pair, the snapshots at Site B need to be reconstituted in Site B's ARX pair (see [cluster-name](#) and [activate configs](#) for details about site-to-site failovers). The snapshot-reconstitution process requires some preparation when you start adding snapshot rules to the configuration. These guidelines show the high-level process for preparing your snapshots, along with the process for reconstituting snapshots in the event of an issue.

**Guidelines: Preparing  
for Snapshot  
Reconstitution**

After you add your first snapshot rule, choose an external repository to hold all of the latest snapshot reports. Choose a filer with a large amount of free space, or monitor the filer's space frequently and remove outdated snapshot reports. Every snapshot report has a timestamp in its name, so it is unique.

The filer should be able to run Perl scripts, and requires the XML::Simple module. You can download this Perl module from CPAN (<http://search.cpan.org>) if your system does not already have it.

Use the `at` command together with `copy ftp`, `copy scp`, `copy {nfs|cifs}`, or `copy smtp` to regularly copy snapshot reports from the ARX to your chosen filer. Use the common string for all of your snapshot reports, together with an "\*" or other wildcard. The report repository should always hold the latest snapshot reports, so that they have the latest back-end snapshot names. For example, this command copies all reports starting with "snap" to an external IP each morning:

```
bstnA(cfg)# at 01:19:18 every 1 day do "copy reports snap*
ftp://ftpuser:ftpuser@172.16.100.183//var/arxSnapRpts/ format xml"
```

The scheduled execution time for CLI command is: 3/30/09 1:19 AM.

You also need a copy of the "snap-recon.pl" script from the "software" directory on the ARX:

```
bstnA# copy software snap-recon.pl
ftp://ftpuser:ftpuser@172.16.100.183//var/arxSnapRpts/
```

**Guidelines:  
Reconstituting ARX  
Snapshots**

You can perform snapshot reconstitution if you have the snap-recon.pl script and the latest set of snapshot reports on a host that supports Perl. Start by running the snap-recon.pl script on that host. This produces a CLI script with a sequence of [snapshot manage](#) commands. By default, the output script is named, "snapRecon.cli." This script has several options; execute the command without any options to get a complete list. You must use the "--report-dir *directory*" option to specify the *directory* that holds the reports. For example, this command sequence lists the files on "client2:/var/arxSnapRpts," runs snap-recon.pl on the reports in the current directory (.), and then shows the new file in the directory:

```
juser@client2:/var/arxSnapRpts$ ls
snap_daily_0_create_20090330010418883.xml snap_hourly_0_create_20090330010652616.xml
snap_daily_0_create_20090330010454303.xml snap_hourly_0_create_20090330010723024.xml
snap_daily_0_create_20090330010524663.xml snap-recon.pl
snap_daily_2_remove_20090330010612220.xml
juser@client2:/var/arxSnapRpts$./snap-recon.pl --report-dir .
juser@client2:/var/arxSnapRpts$ ls
snap_daily_0_create_20090330010418883.xml snap_hourly_0_create_20090330010652616.xml
snap_daily_0_create_20090330010454303.xml snap_hourly_0_create_20090330010723024.xml
snap_daily_0_create_20090330010524663.xml snapRecon.cli
snap_daily_2_remove_20090330010612220.xml snap-recon.pl
juser@client2:/var/arxSnapRpts$
```

**Guidelines:  
Reconstituting ARX  
Snapshots (Cont.)**

You have the option to edit the CLI script before you run it on the ARX. For example, the ARX volumes at a disaster-recovery site may have different names than those at the primary site. The `snapRecon.cli` script has several options for substituting these names; you can use these to rebuild the CLI script, or you can manually edit the CLI script.

Once the CLI script is ready, you can download it to the ARX and run it. Use `copy ftp`, `copy {nfs|cifs}`, or `copy scp` for the download, and use `run` to run it.

A large, complex CLI script may contain errors. If you discover any back-end snapshots that are mismatched with their ARX counterparts, you can use the `snapshot clear` command to remove the ARX snapshot (not the rule) from the configuration. Then you can edit and re-run the script, or you can use `snapshot manage` to manually incorporate the back-end snapshots into the correct ARX snapshots.

**Samples**

```
bstnA(gbl-ns-vol[access~/G])# snapshot rule nightly
This will create a new policy object.
```

```
Create object 'nightly'? [yes/no] yes
bstnA(gbl-ns-vol-snap[access~/G~nightly])# ...
instantiates a new snapshot rule, "nightly," in the current namespace volume.
```

```
bstnA(gbl-ns-vol[medarcv~/lab_equipment])# no snapshot rule hourlySnap
```

The following snapshots are being managed by the rule 'hourlySnap':

```
hourlySnap_0(acopia_27_200707170500_501f705c-8735-11d8-8936-a58a9e4556
df_datavol2)
```

```
hourlySnap_2(acopia_25_200707170300_501f705c-8735-11d8-8936-a58a9e4556
df_datavol2)
```

```
hourlySnap_1(acopia_26_200707170400_501f705c-8735-11d8-8936-a58a9e4556
df_datavol2)
```

If this command is confirmed, the rule is deleted and all associated data related to the aforementioned snapshots will be removed from the switch. The snapshots on the filers will not be removed.

```
Proceed? [yes/no] yes
bstnA(gbl-ns-vol-snap[medarcv~/lab_equipment])# ...
removes a snapshot rule with some existing snapshots remaining on one of its
back-end filers.
```

# snapshot verify

**Purpose** A *snapshot* is a full copy of an ARX volume at one point in time. The ARX volume coordinates snapshots at each of its back-end filers. A back-end filer may clean up some of its snapshots, including those that back an ARX snapshot, to conserve disk space. Use the `snapshot verify` command to confirm that all filer snapshots are in place behind a snapshot rule, or behind a particular ARX snapshot.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer`, `backup-operator`, or `crypto-officer`

**Syntax** `snapshot verify namespace vol-path snapshot-rule [snapshot-instance]`

*namespace* (1-30 characters) identifies the namespace.

*vol-path* (1-1024 characters) is the name of the volume.

*snapshot-rule* (1-1024 characters) is the snapshot rule to verify.

*snapshot-instance* (optional, 1-68) identifies a particular snapshot created by the snapshot rule.

**Default(s)** `None`.

**Guidelines** This command produces a separate verification report for each ARX snapshot. Each report shows the configuration of the snapshot rule, a summary status for each ARX snapshot, and details about the filer snapshot(s) behind each ARX snapshot. See [Figure 30.5 on page 30-54](#) for a sample verification report.

This command verifies filer snapshots asynchronously, allowing you to continue entering CLI commands while the operation proceeds. You can use the `tail reports report-name follow` command to follow the progress of each snapshot verification. You can also use `wait-for snapshot verify` to wait for all snapshot verifications to finish; this is especially useful in CLI scripts.

To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the `snapshot rule` command. For a snapshot rule without a schedule, or for a scheduled snapshot that failed, you can use the `snapshot create` command to manually create a snapshot. To remove filer snapshots from behind a snapshot rule, use `snapshot remove`.

**Samples** bstnA# `snapshot verify medarcv /lab_equipment hourlySnap`

Starting snapshot operation in volume /lab\_equipment, report name:  
snap\_hourly\_0\_verify\_20120229040155141.rpt

Starting snapshot operation in volume /lab\_equipment, report name:  
snap\_hourly\_2\_verify\_20120229040155141.rpt

Starting snapshot operation in volume /lab\_equipment, report name:  
snap\_hourly\_1\_verify\_20120229040155141.rpt

verifies the integrity of all of the “hourlySnap” rule’s snapshots.

bstnA# `snapshot verify medarcv /lab_equipment dailySnap dailySnap_0`

Starting snapshot operation in volume /lab\_equipment, report name:  
snap\_daily\_0\_verify\_20120229040155259.rpt

verifies the most-recent snapshot from the “dailySnap” rule. The report contents appear in [Figure 30.5](#), below.

## snapshot vss-mode

**Purpose** Windows clients can view volume *snapshots*, or point-in-time copies, by clicking on any file or directory in the volume, opening the **Properties** menu, and selecting the **Previous Versions** tab. This is called the Volume Shadowing Service (VSS). The ARX supports VSS for Windows XP and later clients by default, but not Windows 2000 clients. You can use the `snapshot vss-mode pre-xp` command to support VSS for Windows 2000 clients, but stop VSS support for Windows 7 clients.

Some sites prefer to allow snapshot access to administrators only; for those sites, you can use `snapshot vss mode none`. You can offer other methods to access snapshots to administrators, as described in the *Guidelines* below.

Use `no snapshot vss-mode` to return to your default VSS support: VSS for Windows XP (and later) clients.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `snapshot vss-mode {xp | pre-xp | none}`  
`no snapshot vss-mode`

**xp | pre-xp | none** is a required choice. This selects the Windows-client version(s) for whom the volume supports VSS:

**xp** causes the volume to support VSS for Windows XP and later clients. This option excludes Windows 2000 clients.

**pre-xp** extends the volume's VSS support to Windows 2000 clients as well as some later versions of Windows. This option makes VSS unusable for Windows 7 or later clients. You should only use this option if you have Windows 2000 clients, and no Windows 7 or later clients.

**none** prevents all VSS support from this volume. When this is set, all CIFS clients must use other means to access their snapshots. This can be useful in an installation where only administrators are allowed to access snapshots.

**Default(s)** `snapshot vss-mode xp`

---

**Guidelines** This command only applies to managed volumes and CIFS clients. Direct volumes do not support VSS, and NFS clients do not use VSS.

ARX-managed volumes support VSS by default, allowing all Windows-XP and later clients to access their snapshots. Support for the older Windows 2000 VSS precludes support for Windows 7 VSS, so the default excludes Windows 2000 clients; you can use this command to support Windows 2000 clients instead of Windows 7 clients if your site requires it. For installations where only administrators have access to snapshots, you can disable VSS altogether with the `none` option.

Whether or not VSS mode is supported, CIFS clients can always access snapshots through “~snapshot,” a pseudo directory in the volume’s front-end shares. (NFS clients see a different name for this directory; typically “.snapshot.”) One ~snapshot directory resides in every directory in the volume. This directory is not displayed by default, but well-informed clients can access the directory by name (for example, by typing `cd ~snapshot` even though `dir` does not display the ~snapshot directory). To display the directory name in directory listings (such as `dir` and `ls`), use [snapshot directory display](#). You can use the [snapshot directory cifs-name](#) command to change the directory’s name for CIFS clients, and you can use the [snapshot directory nfs-name](#) command to change it for NFS clients.

To create a snapshot rule (which establishes the name of a snapshot set, the number of snapshots to retain in the set, and an optional schedule), use the [snapshot rule](#) command.

**Samples** `bstnA(gbl-ns-vol[medarcv~/lab_equipment])# snapshot vss-mode none`  
stops supporting snapshot access through VSS in the “medarcv~/lab\_equipment” volume. Windows administrators can continue to access snapshots through the volume’s pseudo directories, typically named “~snapshot.”

`bstnA(gbl-ns-vol[acsss~/G])# snapshot vss-mode xp`  
supports VSS for all Windows clients of the “acsss~/G” volume except Windows 2000 clients.

**Related Commands** [snapshot rule](#)  
[snapshot directory cifs-name](#)  
[snapshot directory nfs-name](#)  
[snapshot directory display](#)  
[export \(gbl-cifs\)](#)

## wait-for snapshot create

**Purpose** Use the `wait-for snapshot create` command to wait until a manual snapshot is created on all of the filers behind the volume.

**Mode** (any)

**Security Role(s)** storage-engineer, crypto-officer, or backup-operator

**Syntax** `wait-for snapshot create namespace vol-path rule [snapshot-instance] [timeout timeout]`

*namespace* (1-30 characters) is the name of the namespace.

*vol-path* (1-1024 characters) identifies the volume.

*rule* (1-1024 characters) is the name of the snapshot rule.

*snapshot-instance* (optional; 1-255 characters) identifies a snapshot behind the rule. If you omit this, it waits for the “0” snapshot (for example, “hourly\_0” or “COB\_0”). This is useful for snapshot-create operations that use a non-default snapshot name.

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - none, wait indefinitely

*snapshot-instance* - the default name for the most-recent snapshot: *rule\_0*.

**Guidelines** This command is useful in CLI scripts.

When manually invoking a snapshot rule with the `snapshot create` command, you can use the `wait-for snapshot create` command to wait for the operation to complete on all of the back-end filers. This can be useful for CLI scripts, which you can copy onto the switch (with `copy ftp`, `copy scp`, `copy {nfs|cifs}`, or `copy tftp`), and then `run`.

If you set a *timeout* and it expires before all filer snapshots are finished, the command exits with a warning. To interrupt the `wait-for snapshot create` command, press `<Ctrl-C>`.

**Sample**

```
prtlndA# wait-for snapshot create nemed /vol144 COB timeout 30
```

waits up to 30 seconds for the filers behind the ‘nemed~/vol144’ volume to create their snapshots.

**Related Commands** [snapshot create](#)

---

# wait-for snapshot remove

**Purpose** Use the `wait-for snapshot remove` command to wait until a snapshot-removal operation has completed on every back-end filer behind the volume.

**Mode** (any)

**Security Role(s)** storage-engineer, crypto-officer, or backup-operator

**Syntax** `wait-for snapshot remove namespace vol-path rule [snapshot-instance] [timeout timeout]`

*namespace* (1-30 characters) is the name of the namespace.

*vol-path* (1-1024 characters) identifies the volume.

*rule* (1-1024 characters) is the name of the snapshot rule.

*snapshot-instance* (optional; 1-255 characters) identifies the ARX snapshot. If you omit this, it waits for the removal of all filer snapshots behind the “0” snapshot (for example, “hourly\_0” or “COB\_0”).

*timeout* (optional, 1-2096) is the timeout value in seconds.

**Default(s)** *timeout* - none, wait indefinitely

*snapshot-instance* - the default name for the most-recent snapshot: *rule\_0*.

**Guidelines** This command is useful in CLI scripts.

When removing filer snapshots with the [snapshot remove](#) command, you can use the `wait-for snapshot remove` command to wait for the operation to complete. That is, this command waits for all of the volume’s back-end filers to remove the snapshots behind a particular ARX snapshot. This can be useful for CLI scripts, which you can copy onto the switch (with [copy ftp](#), [copy scp](#), [copy {nfs|cifs}](#), or [copy ftp](#)), and then `run`.

If you set a *timeout* and it expires before the filer snapshots are removed, the command exits with a warning. To interrupt the `wait-for snapshot remove` command, press **<Ctrl-C>**.

**Sample**

```
bstnA> wait-for snapshot remove medarcv /lab_equipment hourlySnap
timeout 60
```

waits up to 60 seconds for the snapshots behind the ‘hourlySnap\_0’ snapshot to be removed from all filer shares behind the ‘medarcv~/lab\_equipment’ volume. (This command defaults to ‘hourlySnap\_0’ because no ARX-snapshot instance was specified in the command.)

# archive

**Purpose** A *file-history archive* holds frequent snapshots of a managed volume's configuration and (typically) its metadata. You can use the **archive** command to make the current snapshot rule send its configuration/metadata snapshots to a pre-configured [file-history archive](#). After the snapshot rule starts sending this data to the archive, you can later query the archive for the volume's state at different times. These queries are useful for finding the back-end locations of the volume's files on different dates, as the volume migrates them from filer to filer.

Use **no archive** to stop sending any snapshots to a file-history archive. This disables any record keeping by the current snapshot rule.

**Mode** gbl-ns-vol-snap

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **archive** *archive-name*  
**no archive**

*archive-name* (1-64 characters) identifies the file-history archive where this rule should copy its configuration/metadata snapshots.

**Default(s)** **no archive**

**Guidelines** You can use [show file-history archive](#) for a list of archives on this ARX, and you can use [show file-history archive ... contents](#) to see the volume configuration and metadata that the archive holds.

Only volume configuration and volume metadata are copied to a file-history archive; a snapshot rule does not copy any client files or directories. Use the [contents](#) command to control the information that is gathered by this snapshot rule.

**Sample** `bstnA(gbl-ns-vol-snap[access~/G~daily])# archive betaArchive`  
uses the file-history archive named "betaArchive" to store configuration and metadata snapshots for the "access~/G" volume.

**Related Commands** [namespace](#) -> [volume](#) -> [snapshot rule](#)  
[contents](#)  
[file-history archive](#)  
[show file-history archive](#)  
[show file-history archive ... contents](#)

## cancel snapshot archive

**Purpose** A *file-history archive* holds daily snapshots of a managed volume's configuration and (typically) its metadata. You create a [snapshot rule](#) in the volume that snapshots this information and then sends the snapshot to the volume's archive. A file-history archive resides on an external filer. In case of an issue with copying the snapshot to the archive filer, you can use the `cancel snapshot archive` command to cancel the copy operation.

**Mode** `priv-exec`

**Security Role(s)** `crypto-officer, storage-engineer, or backup-operator`

**Syntax** `cancel snapshot archive namespace ns volume path rule rule-name`

*ns* (1-30 characters) is the [namespace](#) where a snapshot archive is in progress.

*path* (1-1024 characters) identifies the specific volume, and

*rule-name* (1-1024 characters) is the snapshot rule.

**Default(s)** `None`

**Guidelines** The CLI prompts for confirmation before canceling the archive operation; enter **yes** to proceed.

This cancels the archiving process, not the snapshot process. Use this command to resolve an issue between the ARX and the filer behind the archive's [location](#).

**Sample** `bstnA# cancel snapshot archive namespace medarcv volume /rcrds rule rcrdsArchive`

```
Confirming this command will cause all archiving operations in
namespace 'medarcv' volume '/rcrds'
associated with rule 'rcrdsArchive' to be cancelled. Proceed? [yes/no]
yes
```

                  cancels the archive operation for the "rcrdsArchive" rule.

**Related Commands** [namespace](#) -> [volume](#) -> [snapshot rule](#)  
[file-history archive](#)  
[location](#)

---

## clear file-history archive

**Purpose** *A file-history archive* is where one or more managed volumes store their configuration and metadata snapshots. The managed volumes may store up to seven-years worth of snapshots, possibly taken on a daily basis. This is useful for querying past states of a managed volume, so that you can find file locations as they migrate between the volume's back-end filers. As time goes on, you can use the **clear file-history archive** command to remove older snapshots that are no-longer needed.

**Modes** priv-exec

**Security Role(s)** crypto-officer, storage-engineer, or backup-operator

**Syntax** **clear file-history archive** *name* [**metadata-only**] [**namespace** *ns* **volume** *vol*]

*name* (1-64 characters) identifies a particular file-history archive. This is the particular archive from which you will clear some (or all) file-history records.

**metadata-only** (optional) indicates that you want to delete volume metadata only, not the volume configuration. Volume metadata consumes much more space than the configuration, and it supports the [show file-history virtual-service](#) command for seeking file locations. That command would no longer be supported, but you can still use the [show virtual path-history](#) command to query the front-end service names of various times. If you omit this option, both metadata and configuration are deleted and neither query is supported.

**namespace** *ns* (optional, 1-30 characters) focuses on archive records from the given namespace.

**volume** *vol* (required after the **namespace** option, 1-1024 characters) narrows the focus to the archive records for a single volume.

**Syntax: One Date** **clear file-history archive** *name* [**metadata-only**] **date** *date* ...

*name* is the file-history archive, as described above.

**metadata-only** (optional) is also described above.

**date** *date* (*mm/dd/yyyy*, such as 06/05/2009, or "today") is a specific date for the file-history records to be cleared.

... represents the **namespace** and **volume** options described above.

**Syntax: Contents  
During a Range of  
Dates**

```
clear file-history archive name [metadata-only] start-date
s-date ...
clear file-history archive name [metadata-only] end-date e-date
...
clear ... [metadata-only] start-date s-date end-date e-date ...
```

*name* and **metadata-only** are described above.

**start-date** *s-date* (*mm/dd/yyyy*, such as 03/02/2009) is the beginning of the date range. If you provide no **end-date** (as shown in the first line above), the end date is today.

**end-date** *e-date* (*mm/dd/yyyy*, such as 11/12/2009) is the end of the date range. If you provide no **start-date** (as shown in the second line above), the start is the date of the first snapshot in the file-history archive(s).

... at the end of each syntax line represents the **namespace** and **volume** options described above.

**Syntax: Contents  
During a Time  
Leading Up to a Date**

```
clear file-history archive name [metadata-only] count
{days|weeks|quarters|months|years} before e-date ...
```

*name* and **metadata-only** are described above.

*count* (1-100) is the number of days, weeks, or whatever time unit you choose next.

**days|weeks|quarters|months|years** chooses the time unit. For example, “2 weeks,” “3 quarters,” or “7 months.”

**before** *e-date* (*mm/dd/yyyy*, such as 09/30/2009, or “today”) is the end of the time period.

... at the end of each syntax line represents the **namespace** and **volume** options described above.

**Guidelines**

The CLI prompts for confirmation before clearing any records from the archive file; enter **yes** to proceed.

Before you use this command, you can use [show file-history archive ... contents](#) to list the file-history records on the archive.

**Sample**

```
bstnA# clear file-history archive fileRecordsMed date 01/07/2009
```

```
WARNING: Confirming this command removes all archived metadata and
volume configuration data dated
between '01/07/2009' and '01/07/2009' inclusive from archive
'fileRecordsMed'.
```

```
Proceed? [yes/no] yes
```

```
clears all the file-history records from the fileRecordsMed archive that were
recorded on January 7.
```

[file-history archive](#)  
[show file-history archive ... contents](#)

---

## contents

**Purpose** A *file-history archive* holds daily snapshots of a managed volume's configuration and (typically) its metadata. You can use the **contents** command to choose the contents of this rule's snapshots: client-visible files, volume-configuration data, and/or volume metadata.

Use **no contents** to eliminate one or more types of data from the current rule's snapshots.

**Mode** gbl-ns-vol-snap

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **contents {user-data | volume-config [metadata]}**  
**no contents {user-data | volume-config}**

**user-data | volume-config [metadata]** is a required choice.

**user-data** represents files and directories that are visible to clients. This causes the rule to create snapshots on the volume's storage filers.

**volume-config** represents a configuration file that describes this volume. This option only applies to a managed volume. This does not result in any snapshots unless you also choose the **metadata** option. The volume configuration can support queries with the [show virtual path-history](#) command, but not the [show file-history virtual-service](#) command.

- **metadata** (optional) includes the managed volume's metadata along with its configuration. This causes the rule to take a snapshot at the filer behind the volume's metadata share. The metadata occupies more disk space than the volume configuration, but it also supports file-specific queries with the [show file-history virtual-service](#) command.

**Default(s)** **contents user-data**

**Guidelines** A snapshot rule typically includes volume configuration/metadata *or* user data, not both. If the rule is designed for backing up client data, the default is sufficient. If the rule sends its data to a file-history [archive](#), the contents are usually limited to volume configuration and metadata.

A snapshot rule, if dedicated to volume configuration and metadata, deletes its metadata snapshot as soon as the snapshot is successfully copied to the archive filer. That is, the snapshot rule removes the snapshot from the filer behind the metadata share, and it removes all records of the snapshot from the ARX database. This conserves space on the metadata filer; the snapshot is not required after its contents are safely in the archive.

For a snapshot rule that contains all forms of data, **user-data** and **volume-config**, the rule adheres to its [retain](#) count for all of its snapshots. This includes the snapshots in the volume's filer shares as well as the volume's metadata snapshots. The [snapshot remove](#) command can remove all of the rule's filer snapshots, including those on the volume's metadata filer.

**Sample** `bstnA(gbl-ns-vol-snap[wwmed~/var~a])# contents volume-config metadata`  
causes the “a” snapshot rule to keep the volume’s configuration and metadata in its snapshots.

`bstnA(gbl-ns-vol-snap[wwmed~/var~a])# no contents user-data`  
stops the “a” snapshot rule from taking snapshots on its user-data files.

[archive](#)  
[file-history archive](#)

---

## description (gbl-archive)

**Purpose** Use the optional `description` command to set a descriptive string for the current file-history archive. A *file-history archive* is where managed volumes can store file-location records over a long period of time.

Use the `no` form of the command to delete the description.

**Mode** gbl-archive

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-255 characters) is your description. Surround the text with quotation marks (""") if it contains any spaces.

**Default(s)** `no description`

**Guidelines** This description appears in the output of the [show file-history archive](#) command.

**Sample** `bstnA(gbl-archive[f1Arch])# description "archives for Med Cos"`  
specifies a description for the current file-history archive.

**Related Commands** [file-history archive](#)  
[show file-history archive](#)

## file-history archive

**Purpose** Over time, a file may migrate through multiple shares in a managed volume. You can use the *file-tracking* facility to track these migrations. The **file-history archive** command creates (or edits) a storage depot for file-location records. A single file-history archive can hold these records for multiple managed volumes.

Use the **no** form of the command to remove the configuration for a file-history archive from the ARX database.

**Modes** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **file-history archive *name***  
**no file-history archive *name***

*name* (1-64 characters) is a name you choose for the file-history archive.

**Default(s)** None

**Guidelines** The CLI requests confirmation before creating the new archive object; enter **yes** to confirm. This places you into gbl-archive mode, where you use the **location** command to establish the filer share or ARX volume where the archive resides. You can also enter an optional archive **description (gbl-archive)** in this mode.

You can create up to 24 file-history-archive objects on the ARX.

The file-history records in an archive are snapshots, or point-in-time copies, of a managed volume's metadata and configuration. To keep these records for a particular managed volume, you create a **snapshot rule** in the volume. The contents of the snapshot rule are the volume's configuration and metadata instead of (or in addition to) client files and directories; use the **contents** command to set these options. Then use the **archive** command to send copies of the volume data to this archive.

After one or more snapshot rules post their snapshots in a file-history archive, you can query the archive for file or directory locations at the time of each snapshot. Use the **show file-history archive** command to list all file-history archives, and use **show file-history archive ... contents** to list their contents (that is, their snapshots of volume configuration and metadata). To find which client-visible services existed at a time in the past, use the **show virtual path-history** command. The **show file-history virtual-service** command shows the locations of client files and/or directories on a given date or a range of dates. You can use these commands to find the location of a file on a date when it was backed up, and to find the location of the same file today.

**Samples** bstnA(gbl)# **file-history archive flArch**  
This will create a new archive.

```
Create archive 'flArch'? [yes/no] yes
bstnA(gbl-archive[flArch])# ...
 instantiates a new file-history archive named "flArch."
```

```
bstnA(gbl)# no file-history archive betaArchive
bstnA(gbl)# ...
 removes a file-history archive.
```

**Related Commands** [location](#)  
[description \(gbl-archive\)](#)  
[snapshot rule](#)  
[contents](#)  
[archive](#)  
[show file-history archive](#)  
[show virtual path-history](#)  
[show file-history virtual-service](#)

## find

**Purpose** Use the `find` command to locate one file's back-end filer and path. This finds a file's location as of now, not from a previous time.

**Mode** (any)

**Security Role(s)** `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

**Syntax** `find host hostname-or-ip {nfs | cifs} share-name path path [verbose]`

*hostname-or-ip* identifies a virtual server by its external DNS hostname or Virtual-IP address. Use [show virtual service](#) for a list of all virtual servers and their Virtual IP addresses. (To look up DNS names at an external DNS server, you must first identify the server with the [ip name-server](#) command.)

*nfs* | *cifs* is a required choice, determining the type of share that follows.

*share-name* (1-4096 characters) is the name of the front-end share, as seen by clients. The [show server-mapping](#) command shows all front-end shares on the ARX, in the left column.

*path* (1-4096 characters) is the virtual-file path within the front-end share.

*verbose* (optional) adds the file's NFS filehandles to the output.

`find global-server fqdn {nfs | cifs} share-name path path [verbose]`

*fqdn* (1-255 characters) identifies a global server by its fully-qualified domain name (FQDN). Use [show global service](#) for a list of all global servers and their FQDNs.

The remaining options are described above.

`find namespace namespace path path [verbose]`

*namespace* (1-30 characters) identifies the namespace. Use [show namespace](#) for a list of all namespaces.

*path* (1-4096 characters) is the virtual-file path within the namespace. This is the file path as seen by the client, starting with the volume path.

*verbose* (optional) adds the file's NFS filehandles to the output.

`find wins wins-name {nfs | cifs} share-name path path`

*wins-name* (1-255 characters) identifies a virtual server by its optional [wins-name](#) or one of its optional [wins-alias](#) names.

The remaining options are described above.

**Default(s)** None.

---

**Guidelines** This command finds one file's physical location. To find all file locations behind a namespace, use the `nsck ... report metadata-only` command.

For files in multi-protocol (NFS and CIFS) namespaces, this shows the file's physical location from an NFS point of view and a CIFS point of view.

The output contains several fields to map the ARX-volume location of the file to the file's physical location on the filer:

**Namespace** identifies the namespace that contains the file.

**Logical Path** shows the full path to the file from the client's perspective. This path starts from the root of the volume.

**NFS Physical Location** is an NFS path to the physical file. This appears in `ip-address:path-to-file` format.

**Managed Volume Path** indicates that the *path* is on a **direct** volume, and the physical location is on an ARX **managed-volume** that is standing in as a filer. This field does not appear in the output unless it applies to this query.

**CIFS Physical Location** is a CIFS path to the physical file. This appears in `//ip-address/path-to-file` format. If this is an NFS-only file in a multi-protocol (CIFS and NFS) volume, a message here indicates that the file has an inconsistent name. You can use the `nsck ... report inconsistencies` command to find all of the volume's inconsistent names.

The **verbose** output shows two NFS filehandles for the file:

**Virtual File Handle** is the filehandle that the ARX presents to clients.

**Physical File Handle** is the filehandle that the server gave to the ARX.

The filehandles may be incomplete for the `find namespace` command. Use one of the other versions (such as `find host`) for complete NFS filehandles.

If there are any NFS symlinks (or symbolic links) in the *path*, they appear next. Each symlink in the path appears on one line, with a text arrow (->) pointing to the symlink's target file or directory. For example, a *path* of `"/myvol/dirA/Ydir/sub"` could show this entry, indicating that "dirA" is a symlink:

```
/myvol/dirA -> /myvol/Xdir
```

Each symlink path is fully resolved up to (and not including) the name of the symlink itself. For example, the above symlink indicates the real path for the "dirA" symlink, `"/myvol/Xdir."` If "sub" was also a symlink, its entry starts with that real path, `"/myvol/Xdir,"` instead of the "dirA" name used in the *path*:

```
/myvol/Xdir/Ydir/sub -> myvol/test/dir3
```

This second symlink entry shows the real path up to the "sub" symlink, and points to the real path for "sub."

The object is a symlink appears at the end if the final file or directory in the path is a symlink. This appears in the `"symlink-path -> real-object-path"` format shown above, where the *symlink-path* is a real path up to (but not including) the final name in the path.

**Guidelines: File Tracking** This identifies a file's location now; for a file's location in the past, you can use *file tracking*. This can be useful for finding the correct filer-backup tape for a lost or compromised file.

The file-tracking feature requires some configuration before you can make any file queries. Specifically, a managed volume requires a [snapshot rule](#) to regularly copy its configuration and metadata to a [file-history archive](#). After some copies of metadata have been archived, you can use the [show file-history virtual-service](#) command to query file locations at different dates.

**Samples** `bstnA# find namespace wwmed path /acct/index.html`

```
Namespace: wwmed
Logical path: /acct/index.html
NFS Physical location: 192.168.25.19:/exports/budget/index.html
 finds a file in a namespace.
```

`bstnA# find host 192.168.25.14 nfs /claims path /stats/piechart.ppt`

```
Namespace: insur
Logical path: /claims/stats/piechart.ppt
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS_QTREE/insurance/stats/piechart.ppt
CIFS Physical location: The file/directory on //192.168.25.21/insurance has an inconsistent
name.
```

finds a file behind a virtual server. The virtual server is exporting the file from a multi-protocol namespace, so it shows both NFS and CIFS locations for the file. This file has an inconsistent, NFS-only name.

`bstnA# find global-server ac1.MEDARCH.ORG nfs /claims path /stats/piechart.ppt`

```
Namespace: insur
Logical path: /claims/stats/piechart.ppt
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS_QTREE/insurance/stats/piechart.ppt
CIFS Physical location: The file/directory on //192.168.25.21/insurance has an inconsistent
name.
```

finds the same file behind its global server.

`bstnA# find global-server insur.medarch.org cifs CLAIMS path /index.html verbose`

```
Namespace: insur
Logical path: /claims/index.html
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS_QTREE/insurance/index.html
CIFS Physical location: The file/directory on //192.168.25.21/insurance has an inconsistent
name.
```

NFSv3

```
Virtual File Handle (32 bytes):
0x000000001140000000100000000000700000000000000000000000000000000f00000000
Physical File Handle (32 bytes):
0x92660a0074e7b0002000000000202c09254ed00a58c00484000000bb438000
```

provides a verbose display for another file behind the same global server.

---

```
bstnA# find global-server insur.medarch.org cifs CLAIMS path
/common/reagentLists/stats/acmeIns.txt
```

```
Namespace: insur
Logical path: /claims/common/reagentLists/stats/acmeIns.txt
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS_QTREE/insurance/stats/acmeIns.txt
CIFS Physical location: //192.168.25.21/insurance/stats/acmeIns.txt
```

```
The following symlinks were dereferenced to find this path:
/claims/common/reagentLists -> /claims/specs
/claims/specs/stats -> /claims/stats
```

finds another file behind the same global server, where the logical path contains two symlinks.

**Related Commands** [nsck ... report metadata-only](#)

## location

**Purpose** Use the `location` command to identify the filer or ARX volume to be used for the current file-history archive. A *file-history archive* is where managed volumes can store file-location records over a long period of time. This is the specific storage location for those file-location records.

Use the `no` form of the command to disconnect from the location and disable any file-tracking queries against it.

**Mode** `gbl-archive`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `location filer name {nfs3 | nfs3tcp} share [path path]`  
`location filer name cifs share proxy-user proxy [path path]`  
`location namespace ns volume vol-path [path path]`  
`no location`

*name* (1-64 characters) is [external-filer](#) name for this archive's back-end filer. This is the filer's name from the ARX configuration, which may or may not match the actual host name of the filer.

`nfs3` | `nfs3tcp` chooses the file-access protocol for this location. This is a required choice between NFSv3 over UDP (`nfs3`) or NFSv3 over TCP (`nfs3tcp`).

*share* (1-64 characters) is the name of the back-end export or share.

*path* (optional, 1-1024 characters) is a specific sub path in the back-end share (or ARX volume) where file-location records should be stored. We recommend a path that is hidden from most clients.

*proxy* (for a CIFS filer, 1-32 characters) is the [proxy-user](#) configuration that the ARX uses as its identity when writing to or reading from the back-end-CIFS share. This requires read and write permissions, but does not necessarily need to belong to the Backup Operators group on the filer.

*ns* (1-30 characters) identifies a [namespace](#) on this ARX.

*vol-path* (1-1024 characters) identifies a [volume](#) in the namespace above. If you use this syntax to place the file-history archive in a managed volume, you can use migration policies to balance the file-history records among multiple back-end filers.

**Default(s)** `no location`

**Guidelines** This command determines the physical location for the current [file-history archive](#). Choose a filer or ARX volume with enough storage space for up to 7 years of file-history records. Each file-history record is a snapshot of the volume's configuration (and, typically, its metadata). Use the [snapshot rule](#) command to create a snapshot rule for each desired volume, then use the [contents](#) command to determine whether or not metadata is included in the volume's snapshots.

Multiple managed volumes can share the same file-history archive. The [schedule \(gbl-ns-vol-...snap\)](#) for each volume's snapshot rule determines the frequency of these records, and the amount of space required over 7 years. For a current reading on the disk space consumed in the archive, you can use the [show file-history archive ... contents](#) command.

**Guidelines: Archive Directory Structure**

The snapshot rules create the following directory structure in the location filer's *share* and *path*:

```

/acopia_file_history
 /ARX-name-ARX-GUID
 /yyyy
 /mm
 /dd
 /namespace-name
 /volume-name
 /namespace-name
 /volume-name
 /dd
 ...
 /mm
 ...
 /yyyy
 ...

```

**Guidelines: Client Exposure to the Archive**

The only clients who should access this “acopia\_file\_history” structure are management personnel who understand its purpose. Uninformed clients may accidentally delete important archive records. Choose a location that is inaccessible to most clients. If you use a managed volume as your archive location, use a hidden directory for this data, or dedicate the entire volume to file-history archives and only export/share it to management clients (using [export \(gbl-cifs\)](#) or [export \(gbl-nfs\)](#)).

**Guidelines: Moving the Location**

For cases where the filer location is running low on disk space, you can use the `no location` command to stop all archive writes to the filer. You can then enter a new `location` command to identify the replacement filer or volume. To preserve all of your current file-history records at the new location, move the “acopia\_file\_history” directory from the former location to the new one.

**Samples**

```
bstnA(gbl-archive[fileRecordsMed])# location filer fs4 cifs
arx_file_archv proxy-user repCred
```

sets the location for the “fileRecordsMed” archive to a CIFS share on a back-end filer.

```
bstnA(gbl-archive[flArch])# location namespace wwmed volume /acct path
fileArch
```

sets the location for the “flArch” archive to a path in an ARX volume, “wwmed~/acct.”

**Related Commands**

[file-history archive](#)  
[show file-history archive ... contents](#)  
[contents](#)

## show file-history archive

**Purpose** Over time, a file may migrate through multiple shares in a managed volume. You can set up a managed volume to periodically record its file locations on a [file-history archive](#). Later, you can use commands to query the archive for the location of a file on a given date or dates. The `show file-history archive` command lists the archives on this ARX, their configurations, and the managed volumes that use them.

**Modes** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax** `show file-history archive`  
`show file-history archive name [namespace ns volume vol]`

*name* (optional, 1-64 characters) identifies a particular file-history archive. This invokes a detailed view of the archive, including its configuration and the volumes that use it. If you omit this option, the output is a list of all file-history archives on the ARX.

**namespace** *ns* (optional, 1-30 characters) focuses on archive records from the given namespace.

**volume** *vol* (required after the **namespace** option, 1-1024 characters) narrows the focus to the archive records for a single volume.

**Guidelines** You can use this command to list the current file-history archives on the ARX, or to show the configuration of a particular archive. Before you can list any archives, you must use the [file-history archive](#) command to create an archive, and the [location](#) command to choose the archive's home filer.

The related [show file-history archive ... contents](#) command shows the archive's contents. The archive gets its contents from one or more [snapshot rules](#) in one or more managed volumes. By showing the contents, you can learn how much disk space the archive is using on its back-end filer or ARX volume.

**Guidelines: Summary Output** The summary version of the command lists all file-history archives in a table. The table contains one row per archive with the following fields:

**Archive Name** is the name of the archive, defined by the [file-history archive](#) command.

**Description** offers a short description for the archive. You can set or change this with the [description \(gbl-archive\)](#) command.

- Guidelines: Detailed Output** If you identify a particular archive in the command, the output contains configuration details for that archive:
- Name is the name of the archive, defined by the [file-history archive](#) command.
  - Location is the archive's home filer or home volume. You can use the [location](#) command to change this.
  - Description offers a short description for the archive. You can set or change this with the [description \(gbl-archive\)](#) command.
  - Path is the path under the above location where the archive resides. The [location](#) command controls this.
  - Protocol is "CIFS" or "NFS." This is the file-access protocol that the ARX uses to copy files to the archive. For an archive on an external filer, the [location](#) command controls this. For an archive on a managed volume, this is controlled by the volume's [namespace](#) configuration.
  - Proxy User is the name of the ARX's [proxy-user](#) credentials for accessing the archive filer or managed volume. After the name of the proxy-user configuration, the [windows-domain \(gbl-proxy-user\)](#) and [user \(gbl-proxy-user\)](#) appears in parentheses.
  - Status is "Online" for an archive that is currently usable.
  - FreeSpace shows the current free space on the archive.
  - In use by is the title for a table of snapshot rules that add to this archive. The table contains one row per snapshot rule:
    - Namespace is the [namespace](#) that contains the snapshot rule.
    - Volume identifies the managed [volume](#) for this rule.
    - Snapshot Rule is the name of the [snapshot rule](#) that has written to this archive.

- Samples** `bstnA(gbl)# show file-history archive`  
lists all the file-history archives on the ARX. See [Figure 31.1](#) for sample output.
- `bstnA(gbl)# show file-history archive fileRecordsMed`  
shows details about a particular file-history archive. See [Figure 31.2](#) for sample output.

- Related Commands** [file-history archive](#)  
[show file-history archive ... contents](#)

**Figure 31.1** *show file-history archive*

---

## show file-history archive ... contents

**Purpose** Over time, a file may migrate through multiple shares in a managed volume. You can set up a managed volume to periodically record its file locations on a [file-history archive](#). Later, you can use commands to query the archive for the location of a file on a given date or dates. The `show file-history archive ... contents` command lists the file-history records stored in a particular file-history archive, and shows the amount of disk space that the records occupy.

**Modes** (any)

**Security Role(s)** crypto-officer, storage-engineer, or backup-operator

**Syntax: Contents on One Date** `show file-history archive name contents date date [namespace ns volume vol] [report prefix]`

*name* (1-64 characters) is the file-history archive.

**contents** is a required keyword.

**date *date*** (*mm/dd/yyyy*, such as 05/06/2009, or “today”) is the date for your query.

**namespace *ns*** (optional, 1-30 characters) focuses on archive records from the given namespace.

**volume *vol*** (required after the **namespace** option, 1-1024 characters) narrows the focus to the archive records for a single volume.

**report *prefix*** sends the output to a report file with the given *prefix* (1-255 characters). The report name is *prefix\_archive-name\_mmdyyyHHMM*.rpt, where archive name is “all” or the name you provide in the next option, and the rest is the time the report was created. The exact report name appears at the CLI prompt after you type the command.

**Syntax: Contents During a Range of Dates** `show file-history archive name contents start-date s-date ...`  
`show file-history archive name contents end-date e-date ...`  
`show ... contents start-date s-date end-date e-date ...`

**start-date *s-date*** (*mm/dd/yyyy*, such as 05/06/2009) is the beginning of the date range. If you provide no **end-date** (as shown in the first line above), the end date is today.

**end-date *e-date*** (*mm/dd/yyyy*, such as 01/12/2009) is the end of the date range. If you provide no **start-date** (as shown in the second line above), the start is the date of the first snapshot in the file-history archive(s).

... at the end of each syntax line represents the **namespace**, **volume**, and **report** options described above.

**Syntax: Contents During a Time Leading Up to a Date** `show file-history archive name contents count {days|weeks|quarters|months|years} before e-date ...`

*count* (1-100) is the number of days, weeks, or whatever time unit you choose next.

*days|weeks|quarters|months|years* chooses the time unit. For example, “3 weeks,” “2 quarters,” or “5 months.”

*before e-date* (*mm/dd/yyyy*, such as 09/04/2009) is the end of the time period.

... at the end of each syntax line represents the **namespace**, **volume**, and **report** options described above.

**Guidelines** You can use this command to list the snapshots on a file-history archive. Before you can list any archive contents, you must use the [file-history archive](#) command to create an archive, and the [location](#) command to choose the archive’s home filer or ARX volume.

The archive gets its contents from one or more [snapshot rules](#) in one or more managed volumes. A volume’s snapshot rule contributes to a file-history archive through the following options: the rule must choose the volume’s configuration (and possibly its metadata) with the [contents](#) command, and must identify the file-history archive with the [archive](#) command.

As time goes on, the metadata snapshots on the archive filer occupy progressively-more disk space. You can use this command to assess the consumed space, and you can use the [clear file-history archive](#) command to remove old snapshots from the archive filer.

For a list of all file-history archives, use [show file-history archive](#).

- 
- Guidelines: Output** The output of the archives contents contains three tables.
- Query Parameters displays all of your command-line choices with the following fields:
- Archive,
  - Start date,
  - End date,
  - Namespace, and
  - Volume.
- Switch shows the [hostname](#) and the GUID for the ARX that writes to this archive. It is possible for multiple ARXes to use the same archive filer. You can also see the GUID at the top of the output for [show running-config](#).
- The next table lists the individual archive records. Each record appears in one row, with the following information:
- Archive Date/Time** is the time stamp when the snapshot rule copied the volume configuration (and possibly the volume metadata) into the archive.
  - Namespace:Volume** identifies the managed [volume](#) for this file-history record.
  - Snapshot Rule** is the name of the [snapshot rule](#) that created the record.
  - Config** shows the size of the volume-configuration file.
  - Metadata** shows the size of the volume metadata. This is blank if the snapshot rule's [contents](#) did not include metadata snapshots. Without this, you cannot make the [show file-history virtual-service](#) query against this file-history record.
- Summary** shows the total disk space consumed by these records: total metadata space, total configuration space, and a grand total. You can use this as a guideline to determine the disk space you could reclaim with the [clear file-history archive](#) command.
- Sample** `bstnA(gbl)# show file-history archive fileRecordsMed contents end-date today`  
shows all of the file-history records in the “fileRecordsMed” archive, from the first up to today’s. See [Figure 31.3](#) for sample output.
- Related Commands** [file-history archive](#)  
[show file-history archive](#)

## show file-history virtual-service

**Purpose** Managed volumes migrate files between back-end filers according to your policy settings. This can create a challenge for sites that use data-protection devices to back-up their data; if such a device backs up files from Filer A that later migrate to Filer B, you would create a metadata inconsistency in the managed volume if you restored the files back to Filer A. This command, along with some archiving commands, finds the filer location for any file on any date. You can use a snapshot rule to record a managed volume's configuration and metadata to a *file-history archive*, and later use the `show file-history virtual-service` command to query that archive. The output from this command shows the filer locations for a file or directory on any given date or date range.

**Modes** (any)

**Security Role(s)** crypto-officer, storage-engineer, backup-operator, or operator

**Syntax** `show file-history virtual-service fe-service fe-share time-frame {[file file-name [path dir-path]]} [options]`

*fe-service* (1-1024 characters) is the name of an ARX service used by clients. This is a front-end service created by either the `cifs` or `nfs` commands. You can use the `show virtual path-history` command to find the services that existed on an earlier date, and the paths from those services to your filer shares; service-to-filer mappings may change over time. This can also be the VIP (from the `virtual server` command), a `wins-name`, or a `wins-alias` that existed at the time.

*fe-share* (1-1024 characters) identifies a particular front-end share in the above service. This is created by either the `export (gbl-cifs)` or `export (gbl-nfs)` commands, which export storage from an ARX volume to ARX clients. As above, you may need to use the `show virtual path-history` command to find the shares that existed at the time you are querying. For NFS shares, this is case-sensitive (so that “/vol/aShare” is different from “/vol/ASHARE”), but this is not case-sensitive for CIFS shares.

*time-frame* is a date or range of dates. The output shows the file or directory locations as of these dates. The options are:

**date {today | date}**

for file locations on a specific date. Enter the *date* in *mm/dd/yyyy* format.

**start-date date**

for file locations after the given *date*.

**end-date date**

for file locations before the given *date*.

**start-date date-1 end-date date-2**

for file locations between two dates.

**count {days|weeks|quarters|months|years} before date**

for file locations for a time leading up to a date. The *count* (1-100) is the number of days, weeks, or other time-unit leading up to the *date*.

**Syntax (Cont.)** **[file *file-name*] [path *dir-path*]** is a required choice: you can choose a file name, a directory path, or both.

*file-name* (1-1024 characters) specifies the name of one or more files. You can use special *wildmat* characters (such as \* for zero or more characters, ? for any single character, [a-z] for any lowercase character, or [^0-9] for any character except a number) for a group of similar files.

*dir-path* specifies the name of one or more directories. Use forward slashes (/) for this path, even for CIFS shares. As with the file-name, you can use special *wildmat* characters to specify a group of paths. If you omit this, the path is the root of the volume.

*options* (all optional) are various search and output options that you can apply to any form of this command. If you use more than one of them, they must be in this order:

**recurse**

searches all directories in the volume or **path**. Without this option, the command only searches the root of the volume or path.

**case-sensitive**

makes the search case-sensitive, so that a search for “\*.DOC” does not match the “myfile.doc” file anymore. By default, “\*.DOC” matches “myfile.doc,” “yourfile.Doc,” “herFile.DOC,” or any other case combination for the “.doc” extension.

**verbose**

adds more detail to the output. For a search with only a **path**, this cause the output to show all of the *files* inside all of the matching directories.

**report *prefix***

sends the output to a report file with the given *prefix* (1-255 characters). The report name is *prefix\_archive-name\_mmdyyyHHMM.rpt*, where archive name is “all” or the name you provide in the next option, and the rest is the time the report was created. The exact report name appears at the CLI prompt after you type the command.

**archive *archive-name***

identifies a particular [file-history archive](#) to be searched.

**Guidelines** You can use this command to find file/directory locations at different times, typically to identify a backup tape for a lost file or directory. Before you can find any archived files or directories, you must use the [file-history archive](#) command to create an archive, and the [location](#) command to choose the archive’s home (either an external filer or an ARX volume). The archive gets its file-history records from one or more managed volumes. Each managed volume requires a [snapshot rule](#) to send its configuration and metadata to the archive filer. The snapshot rule contributes to a file-history archive through the following options: the rule must choose the volume’s configuration *and* its metadata with the [contents](#) command, and must identify the file-history archive with the [archive](#) command.

This command finds file locations from the time when a file-history record was copied to a file-history archive. To find the location of a file now, use the [find](#) command or the [nsck ... report metadata-only](#) command.

To restore a file to a managed volume, copy it from its backup tape to a staging area on the back-end filer. The staging area is a directory that is *outside* any imported volume. You can mount both the staging area and the ARX service as a client, then copy the file(s) from the staging area to the volume. Alternatively, you can use the [restore data](#) command to automatically move the file(s) from the staging area to the volume.

**Guidelines: Output** The output contains a table showing the parameters of your query, followed by some configuration information for the file-history archive and ARX service, and then a separate table for each archive record containing one of the chosen files.

Query Parameters contains several fields to summarize your command-line options:

- Virtual Server,
- Export,
- Start date,
- End date,
- File Name,
- Path,
- Archive,
- Case Sensitive,
- Recursive, and
- Verbose.

The next two fields identify the archive and its host ARX. These fields and the tables below only appear if the operation found at least one of the selected files or directories:

**Archive** is the name of the [file-history archive](#) containing these records.

**Hosting Switch** identifies this ARX by its [hostname](#) and by its GUID (also shown in the output of [show running-config](#)).

**Guidelines: Output (Cont.)** The final series of tables contains the found files and/or directories. Each table shows a single matching file in one archive record:

**Archive Date/Time** is the specific time for the current file-location record.

**Global Server** is the [global server](#) that clients use to access the chosen files.

**WINS Name** and

**WINS Aliases** are aliases that clients may use to access the service. You can set these with the [wins-name](#) and [wins-alias](#) commands.

**Dynamic DNS Names** are service names that are registered at the local dynamic-DNS servers (typically, Windows DCs). You can use the [dynamic-dns](#) command to add a new dynamic-DNS name for this service.

**VIP** is the virtual-IP address used by clients to access this ARX service, set by the [virtual server](#) command.

**Namespace** is the ARX [namespace](#) that held the file at the above time.

**Volume Path** identifies the file's [volume](#).

**File Server(s)** shows the single filer that held the file at the time, or the series of filers that may have held the directory. Each filer has three fields to describe the exact location of the file or directory:

- **Shared Path** is the path to the file or directory as seen from the network. This starts with the filer's CIFS-share name or NFS-export name.
- **Physical Path** identifies the exact, file-system path to the file or directory. This path is the one that could be used to find a backup on an external data-protection device.

The ARX accesses the filer's CLI to get the correct physical-path information. The external-filer configuration on the ARX must have the proper [filer-type](#) and [proxy-user \(gbl-filer\)](#) for this access. Otherwise, this path is a "best guess:" for an NFS share, it uses the back-end-export path identified in the [filer](#) command; for a CIFS share, it sends a path query to the filer, requiring the namespace's [proxy-user \(gbl-ns\)](#) to be in the Administrators group.

- **File Name** is the name of the file or directory.
- **Symlink Name** appears instead of File Name if the file or directory is a symlink. This is the name of the symlink itself, not the symlink's target. You must retrieve the symlink from a backup tape to discover its target.

**Samples** `bstnA(gbl)# show file-history virtual-service ac1.medarch.org labs date 04/23/2009 file index.html`

shows the location of a file named "index.html" in the "ac1.medarch.org~labs" share. The file's location is as of a particular date, April 23. See [Figure 31.4](#) for sample output.

`bstnA# show file-history virtual-service ac1.medarch.org ARCHIVES date today path planA recurse`

shows the location of all directories named "planA" in the "ac1.medarch.org~ARCHIVES" share. These directories are in the given locations as of today. See [Figure 31.5](#) for sample output.

**Related Commands** [show virtual path-history](#)  
[file-history archive](#)  
[find](#)  
[restore data](#)

---

## show virtual path-history

**Purpose** Service and volume configurations change over time, possibly making it difficult to make a proper file-tracking query about an earlier date. To make a query about file locations as of six-months ago, you must first know which ARX services existed at the time, and the paths from those client-visible services to the back-end filers and their file-systems. This is known as the *path history* of your ARX. From any mode, you can use the `show virtual path-history` command to list the front-end services, namespaces, and volumes from a given date or range of dates.

**Modes** (any)

**Security Role(s)** crypto-officer, storage-engineer, or backup-operator

**Syntax: One Date** `show virtual path-history date date [report prefix] [archive arch-name] [verbose]`

*date* (*mm/dd/yyyy*, such as 11/12/2009, or **today**) is the exact date for the query.

**report *prefix*** (optional, 1-1024 characters) sends the output to a report file. Each report has a unique name in the following format:

*prefix\_archive\_yyyymmddHHMM.rpt*

where the *prefix* is part of this option, the *archive* is “all” or a specific *arch-name* (see below), and *yyymmddHHMM* is the time the report was created. For example, “fRec\_all\_200903031200.rpt” could be the name for one report with the “fRec” prefix.

**archive *arch-name*** (optional, 1-64 characters) focuses on path history from a single [file-history archive](#).

**verbose** (optional) expands the output with additional details.

**Syntax: A Range of Dates**

```
show virtual path-history start-date s-date ...
show virtual path-history end-date e-date ...
show virtual path-history start-date s-date end-date e-date ...
```

**start-date *s-date*** (*mm/dd/yyyy*, such as 05/06/2009) is the beginning of the date range. If you provide no **end-date** (as shown in the first line above), the end date is today.

**end-date *e-date*** (*mm/dd/yyyy*, such as 10/24/2009) is the end of the date range. If you provide no **start-date** (as shown in the second line above), the start is the date of the first snapshot in the file-history archive(s).

... represents the **report**, **archive**, and **verbose** options described above.

**Syntax: Time Leading Up to a Date**

```
show virtual path-history count
{days|weeks|quarters|months|years} before e-date ...
```

**count** (1-100) is the number of days, weeks, or whatever time unit you choose next.

**days|weeks|quarters|months|years** chooses the time unit. For example, “2 weeks,” “5 days,” or “6 months.”

**before *e-date*** (*mm/dd/yyyy*, such as 03/02/2009) is the end of the time period.

... represents the **report**, **archive**, and **verbose** options described above.

**Guidelines** You can use this command to find ARX-service and storage configurations at different times, typically to prepare for using the [show file-history virtual-service](#) command. Before you can find any volume-configuration information, you must use the [file-history archive](#) command to create an archive, and the [location](#) command to choose the archive's home (an ARX volume or an external filer). The archive gets its volume-configuration records from one or more managed volumes. Each managed volume requires a [snapshot rule](#) to send its volume configuration to the archive filer. The snapshot rule contributes to a file-history archive through the following options: the rule must choose the volume's configuration with the [contents](#) command, and must identify the file-history archive with the [archive](#) command.

The output contains a table with the chosen date range followed by one table per matching file-history record.

Query Parameters contains several fields to summarize your command-line options:

- Start date,
- End date,
- Archive, and
- Verbose.

As of *date* is the heading for every file-history record in your date range. If more than one volume sends its records to this archive, you may see more than one record with the same date.

The next series of fields describes the configuration for the archive and the service:

**Archive** is the name of the [file-history archive](#) containing this record.

**Hosting Switch** identifies this ARX by its [hostname](#).

**Global Server** is the [global server](#) that clients use to access the Volume, below.

**WINS Name** and

**WINS Alias** are aliases that clients may use to access the service. You can set these with the [wins-name](#) and [wins-alias](#) commands.

**Dynamic DNS Names** are service names that are registered at the local dynamic-DNS servers (typically, Windows DCs). You can use the [dynamic-dns](#) command to add a new dynamic-DNS name for this service.

**VIP** is the virtual-IP address used by clients to access this ARX service, set by the [virtual server](#) command.

**Namespace** is the ARX [namespace](#) to which this record applies.

**Volume** identifies the [volume](#) for this file-history record.

**Guidelines (Cont.)** A table of the volume's shares appears next. This shows the back-end shares that were included in the volume when the record was created. Each row shows one share, with the following fields:

**Share** is the ARX name of the [share](#).

**Shared Path** is the filer's network-accessible path for the above share. The volume imported the filer share through this path, and used the share's storage for client files and directories when the record was created.

-> **Physical Path** is the actual file-system path on the filer. An external data-recovery application uses file-system paths to identify the files that it has backed up. You can use this to identify the backup files that apply to the volume as of this particular date. The verbose option adds the filer's IP address to the end of this output.

The ARX accesses the filer's CLI to get the correct physical-path information. The external-filer configuration on the ARX must have the proper [filer-type](#) and [proxy-user \(gbl-filer\)](#) for this access. Otherwise, this path is a "best guess:" for an NFS share, it uses the back-end-export path identified in the [filer](#) command; for a CIFS share, it sends a path query to the filer, requiring the namespace's [proxy-user \(gbl-ns\)](#) to be in the Administrators group.

The final table shows the exports that were used by the ARX's clients when the record was taken. Each row contains one client-visible export of the above volume, with the following fields:

**Export** is the exported name of the managed volume, or one of its sub paths.

**Relative Virtual Path** is the managed-volume path that clients saw as the root of the above Export.

**Sample**

```
bstnA(gbl)# show virtual path-history end-date 06/05/2009 report
pathsTilJune verbose
Generating report: pathsTilJune_all_200901260629.rpt
```

shows all path histories up to June 5, including verbose details, and sends them to a report.

**Related Commands** [file-history archive](#)  
[show file-history virtual-service](#)

---

---

Restore Data

---

---

---

## cancel restore data

**Purpose** A *restore data* operation restores files from an external filer to a managed volume; the `cancel restore data` command stops a restore operation.

**Modes** `priv-exec`

**Security Role(s)** `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `backup-operator`

**Syntax** `cancel restore data namespace volume volume path path`

*namespace* (1-30 characters) is the namespace to which files are being restored. Use the [show restore data](#) command for a list of namespaces where restores are running.

*volume* (1-1024 characters) specifies the namespace volume where the restore is occurring.

*path* (1-1024 characters) specifies the volume directory. This path is relative to the *volume* root, above. Use forward slashes (/) for NFS or CIFS paths.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before canceling the restore operation; enter **yes** to continue.

Use the [restore data](#) command to start restoring files and directories to a volume. Restore operations happen in the background while you continue to use the CLI; you can use the [wait-for restore data](#) command to block the CLI until the restore is complete. To show all restore operations, use [show restore data](#).

**Sample**

```
bstnA# cancel restore data wwmed volume /acct path /
Cancel specified restore operations? [yes/no] yes
bstnA#
```

          cancels the restore operation in progress for the root directory in the "wwmed~/acct" volume.

**Related Commands** [restore data](#)  
[wait-for restore data](#)  
[show restore data](#)

## clear restore data

**Purpose** The ARX holds its restore-operation records indefinitely, so that you can see the results of every restore operation through `show restore data`. Use the `clear restore data` command to remove restore operations from this running history.

**Mode** priv-exec

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or backup-operator

**Syntax**

```
clear restore data
clear restore data namespace
clear restore data namespace volume vol-path
clear restore data namespace volume vol-path path path
```

The *namespace*, *vol-path*, and *path* arguments mimic the ones used in the `restore data` command. These identify one or more restore operations; if you omit all of them, the command clears all restore-operation records from the switch.

*namespace* (1-30 characters) specifies a namespace where one or more restores have occurred.

*vol-path* (optional, 1-1024 characters) specifies a volume. Use forward slashes (/) for all volumes, including CIFS.

*path* (optional, 1-1024 characters) identifies a particular path that has been restored. As with volumes, use forward slashes in all paths.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before deleting any restore records. Enter **yes** to continue.

Use `show restore data` to show all recorded restore operations. This command clears them; after you run it, the `show restore data` command no longer displays the cleared operation(s).

The `restore data` command starts a restore operation (which runs in the background while you continue to use the CLI), `cancel restore data` cancels a running restore, and `wait-for restore data` blocks the CLI until a running restore completes.

**Samples**

```
bstnA# clear restore data wwmed
Clear restore data records? [yes/no] yes
bstnA#
clears all restore-operation records for the "wwmed" namespace.
```

```
bstnA# clear restore data
Clear restore data records? [yes/no] yes
bstnA#
clears all restore records from the switch. The show restore data command displays nothing after you do this.
```

**Related Commands** [restore data](#)  
[show restore data](#)  
[cancel restore data](#)  
[wait-for restore data](#)

## restore data

|                         |                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | To restore files and/or directories to a namespace volume, use the <code>restore data</code> command.                                                                       |
| <b>Modes</b>            | priv-exec                                                                                                                                                                   |
| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or backup-operator                                                                                  |
| <b>Syntax</b>           | <code>restore data namespace volume volume path dest-path<br/>filer ext-filer {nfs nfs-export   cifs cifs-share}+ source-path<br/>src-path [recurse] [remove-source]</code> |

*namespace*, *volume volume*, and *path dest-path* specify the destination for the restored files:

*namespace* (1-30 characters) specifies the destination namespace for the restore operation. Use the [show namespace](#) command for a list of configured namespaces.

*volume* (1-1024 characters) is the volume to be restored. All of the namespace's volumes appear in the `show namespace` output.

*dest-path* (1-1024 characters) is the file or directory to be restored (for example, "var/log"). This path is relative to the *volume* root, above. If this is a directory, the restored files are placed into a new subdirectory under this path named "restore." Use forward slashes (/) for NFS or CIFS paths.

*filer ext-filer*, *{nfs ... | cifs ...}+*, and *source-path src-path* define the source share for the restore operation:

*ext-filer* (1-64 characters) is the external filer where the backed-up files reside. This must be defined on the ARX as an external filer. Use the [show external-filer](#) command for a list of configured external filers.

*{nfs nfs-export | cifs cifs-share}+* is a required choice. For multi-protocol (NFS and CIFS) filers, you must specify both.

- *nfs-export* (1-1024 characters) is an NFS-export path.
- *cifs-share* (also 1-1024 characters) is a CIFS-share name.

*src-path* (1-1024 characters) chooses the file or directory on the source share (for example, "/backups/vol3"). This path is relative to the *nfs-export* and/or *cifs-share* root, above. Use forward slashes (/) for NFS or CIFS paths.

You can enter the final two options in any order, or you can omit them:

**recurse** causes the restore operation to descend into subdirectories.

**remove-source** removes all of the selected files and directories from the source share after a successful restore. If there is any failure, the restore operation leaves the source share intact.

**Default(s)** **recurse** is off; the restore only restores from the top of the *src-dir-path* to the top of the *dir-path* without descending into any child directories.

**remove-source** is off; the source share is unaffected by the restore operation.

---

**Guidelines: Backups** You can perform backup operations on back-end filers using the same procedure that was employed prior to the introduction of the ARX. You can use a data-protection device, called a *backup server* in this manual, to coordinate NDMP backups from your filers to tape.

**Guidelines: Finding the Backup File** Before you begin a restore operation, you need to find the backed-up version of the lost or corrupted file. To accomplish this, you must first find the filer that held the file at the time of the desired backup. Assuming you know the service FQDN or VIP, the front-end-share name, and the file path of the lost file, you can use the [find](#) command to find the actual namespace, volume, and filer where the file currently resides.

For sites where migrations are frequent, or where backups are infrequent, you may need *file tracking* to find a file location on a particular backup date. The file-tracking process involves regular snapshots of the managed volume's configuration and metadata, which are stored on a [file-history archive](#). Once this archive process is running, you can use the [show virtual path-history](#) command to query the archive for service names at the time of an earlier backup. This also shows the namespace, volumes, and filers that mapped to the service names at the time. Armed with this historical information, you can use [show file-history virtual-service](#) to query the archive for the file location at a given time.

Once you find the filer location for the lost file, you can go to your backup server to recover the file.

**Guidelines: Sending the File to a Staging Area** Recover the file from the backup server and place it onto a *staging area* on a filer (typically, the same filer where the file was originally backed up). A staging area is a directory that is *not imported* into any managed volume.

The staging-area directory usually resides on a filer that is already defined as an external filer in the ARX configuration. If not, use the [external-filer](#) and [ip address](#) commands to add the new filer to the ARX database.

◆ **Note**

---

*The external-filer configuration is required so that the ARX can support multi-homed backup servers for its restore operations.*

**Guidelines: Restoring Files from an External Staging Area** The `restore data` command restores the files and directories from the staging-area directory to their managed volume, which in turn sends the files/directories to the filer(s) specified by your storage policies.

Each restore operation has a unique job ID and generates a report of its progress. The reports follow this naming convention: "restore.job-id.volume.rpt." Use [show reports](#) to list all reports, including restore reports. To follow the progress of the restore operation, you can use [tail reports report-name](#) follow. A sample of this report appears in [Figure 32.1 on page 32-8](#).

To view all restore operations (past and present), use [show restore data](#). You can use the [cancel restore data](#) command to cancel a restore operation that is currently underway. To remove old records of restore operations, you can use the [clear restore data](#) command. Restore operations occur in the background so that you can continue to issue CLI commands; to pause the CLI until the restore operation finishes, use [wait-for restore data](#).

**Guidelines: Invoking  
Restore from a  
Remote Host**

From any remote host that runs the Secure SHell (SSH) program, you can run the `restore data` command and show the output of the report. Use the following syntax with `ssh` at the remote machine:

```
ssh admin-user@mip "restore-data..."
```

where

*admin-user* is a valid user (use [show users](#) to list all of them),

*mip* is a management-IP address for this ARX (use [show interface mgmt](#) and/or [show interface vlan](#) to list them), and

*restore-data...* is the restore data command, surrounded by quotation marks ("").

**Samples**

```
bstnA# restore data wwmed volume /acct path /filer das1 nfs
/exports/backups source-path /acct recurse
Scheduling restore operation on switch bstnA, report name:
restore.5._acct.rpt
bstnA#
```

restores files to the "wwmed~/acct" volume from an NFS-only share on a filer named "das1."

```
bstnA# restore data insur volume /claims path /stats filer nasE1 nfs
/root_vdm_4/backups cifs BACKUPS source-path /stats recurse
Scheduling restore operation on switch bstnA, report name:
restore.7._claims.rpt
bstnA#
```

restores files to the "insur~/claims" volume from a multi-protocol filer named "nasE1." This restores one directory tree in the volume, "/stats." A sample report appears below in [Figure 32.1](#).

## show restore data

**Purpose** Use the `show restore data` command to show the results of all restore operations.

**Modes** (any)

**Security Role(s)** operator or backup operator (any)

**Syntax** `show restore data`  
`show restore data namespace`  
`show restore data namespace volume vol-path`  
`show restore data namespace volume vol-path path path`

*namespace* (optional, 1-30 characters) is the name of a namespace. Use [show namespace](#) for a list of all configured namespaces. If you omit this (and all other options), the output includes all recorded restore operations on all namespaces.

*vol-path* (optional, 1-1024 characters) focuses on a particular volume. Use forward slashes (/) for all volumes, including CIFS.

*path* (optional, 1-1024 characters) narrows the focus further, to a particular path within the volume. As with volumes, use forward slashes in all paths.

**Default(s)** None.

**Guidelines** This command shows all restore operations, past and present. They are organized by namespace, volume, and in-volume path that was restored:

**Namespace** is a namespace where at least one restore operation occurred.

**Volume** is one volume that was restored.

**Path** is the specific path that was restored. This contains details about the operation:

**Options** are “recurse” and/or “remove-source.” This does not appear unless the user selected one of these options. They are options in the [restore data](#) command.

**Source Filer** is the name and IP address of the external filer used as a source. This is also specified in the [restore data](#) command.

- **NFS Source** identifies the NFS export used as a source share. This only appears if NFS was used in the restore operation.
- **CIFS Source** identifies the CIFS share used as a source. This only appears if CIFS was used in the restore operation.

**Status** is “Pending,” “Restoring,” “Pending Cancel,” “Canceling,” “Success,” or “Failed.” A typical restore operation goes from “Pending” to “Restoring” to “Success.” Use the [cancel restore data](#) command to cancel the restore operation. For details on the restore operation’s progress, you can look at the restore report, identified below.

**Report Name** is the name of a detailed report about the restore operation (and the ARX where the report is stored). You can use the [show reports](#) command to view the report.

**Error** only appears if the restore failed. This summarizes the problem.

**Guidelines (Cont.)**

Items Found are the files and/or directories that were found on the Source Filer share.

Items Transferred are the files and/or directories that were successfully restored to the target volume.

Failures is the number of files and/or directories that were *not* restored.

Total Bytes Restored is the number of bytes in the successfully-transferred files and directories.

Completed at shows the date and time when the restore operation finished.

This output grows with every run of the `restore data` command. Use [clear restore data](#) to clear all restore operations from this output (without deleting any of the detailed restore reports; use [delete](#) to remove those).

**Samples**

`bstnA# show restore data`

displays the state of all restore operations for all namespaces. [Figure 32.2](#) shows sample output.

`bstnA# show restore data insur volume /claims`

displays the state of all restore operations for a multi-protocol (NFS and CIFS) volume, “insur~/claims.” [Figure 32.3 on page 32-13](#) shows sample output.

**Related Commands**

[restore data](#)

[clear restore data](#)

[cancel restore data](#)

*Figure 32.2 Sample Output: show restore data*

```
bstnA# show restore data
```

```
Namespace: wwmmed

Completed at: Sat Feb 27 01:43:54 2010
```

## wait-for restore data

**Purpose** Use the `wait-for restore data` command to block the CLI until one or more restore operations completes.

**Mode** (any)

**Security Role(s)** `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `backup-operator`

**Syntax** `wait-for restore data [timeout timeout]`  
`wait-for restore data namespace [timeout timeout]`  
`wait-for restore data namespace volume vol-path [timeout timeout]`  
`wait-for restore data namespace volume vol-path path path [timeout timeout]`

The *namespace*, *vol-path*, and *path* arguments mimic the ones used in the [restore data](#) command. These identify one or more restore operations; if you omit all of them, the command waits for all restore operations on the switch.

*namespace* (1-30 characters) specifies a namespace where one or more restore operations are occurring.

*vol-path* (optional, 1-1024 characters) specifies a volume. Use forward slashes (/) for all volumes, including CIFS.

*path* (optional, 1-1024 characters) identifies a particular path that is being restored. As with volumes, use forward slashes in all paths.

*timeout* (optional, 1-2096) is the timeout value, specified in seconds. If this timer expires before the restore operation completes, the command exits with a warning.

**Default(s)** *timeout* - 0 (zero, meaning “wait indefinitely”)

**Guidelines** The `wait-for restore data` command waits for a specified restore operation to complete.

To interrupt the `wait-for restore data` command, press <Ctrl-C>. Use [cancel restore data](#) to cancel the restore operation altogether.

**Samples** `bstnA# wait-for restore data timeout 60`  
waits for all restore operations on the switch to complete. If they do not complete in 60 seconds, the command returns with a warning.

`bstnA> wait-for restore data insur timeout 120`  
waits for all restore operations in the “insur” namespace to complete. If they do not complete in 120 seconds, the command returns with a warning.

**Related Commands** [restore data](#)  
[show restore data](#)  
[cancel restore data](#)

33

---

---

## Running and Global-Configs

---

---

---

# clear global-config

**Purpose** \* To be used for evaluations and emergency recovery procedures only. Contact your F5 representative for more information.\*

Use the `clear global-config` command to erase all global-config parameters.

The *global-config* parameters are shared among both ARX peers in a redundant pair: primarily, namespaces and global servers. The traditional *running-config* applies only to the local switch.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `clear global-config`

**Default(s)** None

**Guidelines** This causes the switch to reboot. A prompt asks for confirmation before the CLI reboots the switch; enter `yes` to proceed.

If the switch is part of a redundant pair, you can only run this command on the senior switch. This reboots both switches in the pair.

Use this command to remove all namespaces, global servers, and other global-config parameters. This can be a useful alternative to [delete startup-config](#), which deletes all *running-config* and global-config parameters. By preserving the *running-config* parameters, the network configuration remains intact; you can use the in-band (VLAN) management interfaces after clearing the global config.

However, this may leave back-end filers in a non-deterministic state. We strongly recommend using [nsck ... destage](#) on every active namespace before using this command.

**Sample** `bstnA# clear global-config`

This removes all global configuration and reboots both chassis in the redundant pair in order to ensure services are removed properly.

```
Are you sure? [yes/no] yes
```

```
bstnA#
```

```
Broadcast message (Fri Sep 24 13:53:15 2004):
```

```
The system is going down for reboot NOW!
```

```
...
```

```
deletes all namespaces, global servers, and other shared parameters.
```

**Related Commands** [delete startup-config](#)  
[nsck ... destage](#)

## copy global-config

**Purpose** The *global-config* parameters are shared among both ARXes in a redundant pair. The traditional *running-config* applies only to the local switch. We recommend copying the global config to a remote server after any global-configuration change. Use the *copy global-config* command to copy the switch's global configuration to a local file, a remote server, an ARX volume, a remote ARX, or an email recipient.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax: FTP Upload** `copy global-config ftp://[user[:password]@]server/file-name`

`ftp://[user[:password]@]server/file-name` (1-1024 characters) is the syntax for uploading the startup-config:

`user[:password]@` (optional) are the credentials for FTP access. If you omit them altogether, they default to the credentials set by the `ip ftp-user` command. If you enter the *user* but omit the *password*, the CLI prompts for the password before continuing.

*server* is the IP address or hostname for the FTP server.

*file-name* is the destination-file path. Lead with an extra slash (“/”) if the path is absolute (for example, “ftp://10.1.1.5//var/cfgs/ac-gbl.cfg”). Use only one slash if the path is local to the home directory for *user* (for example, “ftp://10.1.1.5/ac-gbl.cfg”).

**Syntax: SCP Upload** `copy global-config scp://user@server:dest-file [accept-host-key]`

`scp://user@server:dest-file` (1-1024 characters) is the URL for the destination file:

`user@` is the username to present to the other end of the SCP connection. This user must be valid at the remote host.

`server:` is the IP address or hostname for SCP host. End with a colon (:).

*dest-file* is the destination-file path. Lead with a slash (“/”) if the path is absolute (for example, “scp://root@10.1.1.5:/var/configs/gblConf”). Use no slash if the path is local to the home directory for *user* (for example, “scp://root@10.1.1.5:myGlobal.cfg”).

**accept-host-key** (optional) indicates that if the other end of the connection has an unknown SSH host key (that is, if it is new, or if its key has changed since the last time the host was contacted), the ARX should accept the new host key and continue with the upload. Otherwise, the ARX stops the upload if the host presents an unknown key.

---

**Syntax: Sending to an ARX Volume**    `copy global-config {nfs|cifs} namespace vol file-name`

**nfs | cifs** is a required choice. This chooses the protocol for the file transfer.

**namespace** (1-30 characters) identifies the namespace to hold the global-config file.

**vol** (1-1024 characters) is the volume name.

**file-name** (1-1024 characters) is the path to the config file, starting at the root of the volume.

**Syntax: Sending to Another ARX**    `copy global-config ron remote-arx {configs|scripts} file-name`

**remote-arx** (1-30 characters) is the [hostname](#) of the remote ARX to which you are sending the copy. This must be an ARX in the same Resilient-Overlay Network (RON); use [show ron](#) for a full list of hosts on the RON. The remote host checks your administrative credentials to confirm you have permission to copy the configuration file: the credentials are the [ip ron-user](#), or the credentials you used to log into the CLI if no RON user is set.

**configs | scripts** is the destination directory at the remote host. This is a required choice.

**file-name** (1-1024 characters) is a destination-file name, for example, gblcfgbeta01.cfg, to which you copy/save the switch's global-configuration information.

**Syntax: TFTP Upload**    `copy global-config tftp://server/file-name`

**tftp://server/file-name** (1-1024 characters) is the URL for the global-config file:

**server** is the machine name (for example, "mymachine.myco.com").

**file-name** is the desired path name for the file. Lead with an extra slash (/) if the path is absolute: for example, "...myserver//var/configs/gblConf" specifies /var/configs/gblConf on "myserver." Use only one slash if the path is local to the server's "tftpboot" directory. This conforms with the specification for FTP URLs in RFC 1738.

**Syntax: Send in an Email**    `copy global-config smtp://[email-address/]file-name`

**smtp://[email-address/]file-name** (1-1024 characters) is an email destination for the file:

**smtp://** is required. This declares that the destination is an email address.

**email-address** (optional) is the recipient of the email in *username@host* format (for example, "jsmith@myco.com"). If you omit this, the CLI uses the default address set by the [cfg-smtp to](#) command.

**file-name** is the name of the global-config file. This is sent as an attachment to the outbound email message.

You must configure SMTP on the ARX before you use this syntax. Start with the [smtp](#) command in [cfg](#) mode.

**Syntax: Local Copy** `copy global-config {configs | diag-info | scripts} file-name`

`configs | diag-info | scripts` is the destination directory. This is a required choice.

*file-name* (1-1024 characters) is a destination-file name, for example, `gblcfgbeta01.cfg`, to which you copy/save the switch's global-configuration information.

**Default(s)** None

**Guidelines** If you upload using SCP (a secure protocol), the CLI asks for a password. Provide a password for *user*. The user name and password must be valid at the SCP server. The CLI also prompts for a password if you use FTP and enter a *user* without a *password*. Use this command to save the current global config to a file. The global-config contains all parameters that you set in `gbl` mode, such as namespaces, filers, and global servers. These parameters are shared between both peers in a redundant pair. You should make a copy of the global config after any change to these parameters. To save the global-config on a regular schedule, you can use this command with the `at` command.

You can use this file later to recreate the global configuration, if necessary; copy it to the scripts or config directory and use the `run scripts config-file-name` command.

◆ **Note**

---

*A global-config run changes the global config for both members of a redundant pair.*

Use `show directories` to view all the local-directory listings.

To save all the local-config parameters, such as layer-2 and layer-3, use the `copy running-config` command. To save both running- and global-config into a single file, use `copy startup-config`.

To view the global config, use `show global-config`.

Note that this command, `copy global-config`, immediately creates the global-config file from the database and then copies it, so its date stamp is either the time you invoked the command or the time that the file was created at the remote server. This is different from `copy configs boot-config`, which copies a file that was created when the system was installed: the boot-config file may have a time stamp with the system-install time.

**Samples** `bstnA# copy global-config scripts ron.cfg`  
copies the global config into a new file, "ron.cfg," in the scripts directory.

```
bstnA# copy global-config
ftp://ftpuser:ftpuser@10.1.1.19/acopia-gbl.cfg
copies the global config to an FTP server at 10.1.1.19.
```

```
bstnA# copy global-config scp://juser@10.1.1.35:acopia-gbl.cfg
Password: jpasswd
copies the running config to an SCP server at 10.1.1.35.
```

[copy running-config](#)  
[copy startup-config](#)  
[show global-config](#)  
[at](#)

## copy running-config

**Purpose** The *running-config* is the parameters that apply to the local switch only, as opposed to a redundant peer. We strongly recommend saving the running-config after any configuration change. Use the **copy running-config** command to copy the switch's current running configuration to a local file, upload it to a remote server, place it into an ARX volume, or send it in an email message.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax: FTP Upload** **copy running-config ftp://[*user[:password]*]@*server/file-name***

**ftp://[*user[:password]*]@*server/file-name*** (1-1024 characters) is the syntax for uploading the startup-config:

***user[:password]*@** (optional) are the credentials for FTP access. If you omit them altogether, they default to the credentials set by the **ip ftp-user** command. If you enter the *user* but omit the *password*, the CLI prompts for the password before continuing.

***server*** is the IP address or hostname for the FTP server.

***file-name*** is the destination-file path. Lead with an extra slash (“/”) if the path is absolute (for example, “ftp://10.1.1.5//var/cfgs/ac-run.cfg”). Use only one slash if the path is local to the home directory for *user* (for example, “ftp://10.1.1.5/ac-run.cfg”).

**Syntax: SCP Upload** **copy running-config scp://*user@server:dest-file***  
**[*accept-host-key*]**

**scp://*user@server:dest-file*** (1-1024 characters) is the URL for the destination file:

***user@*** is the username to present to the other end of the SCP connection. This user must be valid at the remote host.

***server:*** is the IP address or hostname for SCP host. End with a colon (:).

***dest-file*** is the destination-file path. Lead with a slash (“/”) if the path is absolute (for example, “scp://root@10.1.1.5:/var/configs/runConf”). Use no slash if the path is local to the home directory for *user* (for example, “scp://root@10.1.1.5:myrun.cfg”).

**accept-host-key** (optional) indicates that if the other end of the connection has an unknown SSH host key (that is, if it is new, or if its key has changed since the last time the host was contacted), the ARX should accept the new host key and continue with the upload. Otherwise, the ARX stops the upload if the host presents an unknown key.

---

**Syntax: Sending to an ARX Volume**    `copy running-config {nfs|cifs} namespace vol file-name`

**nfs** | **cifs** is a required choice. This chooses the protocol for the file transfer.

**namespace** (1-30 characters) identifies the namespace to hold the running-config file.

**vol** (1-1024 characters) is the volume name.

**file-name** (1-1024 characters) is the path to the config file, starting at the root of the volume.

**Syntax: Sending to Another ARX**    `copy running-config ron remote-arx {configs|scripts} file-name`

**remote-arx** (1-30 characters) is the [hostname](#) of the remote ARX to which you are sending the copy. This must be an ARX in the same Resilient-Overlay Network (RON); use [show ron](#) for a full list of hosts on the RON. The remote host checks your administrative credentials to confirm you have permission to copy the configuration file: the credentials are the [ip ron-user](#), or the credentials you used to log into the CLI if no RON user is set.

**configs** | **scripts** is the destination directory at the remote host. This is a required choice.

**file-name** (1-1024 characters) is a destination-file name, for example, `rnngcfgPrtlnd.cfg`, to which you copy/save the switch's running-configuration information.

**Syntax: TFTP Upload**    `copy running-config tftp://server/file-name`

**tftp://server/file-name** (1-1024 characters) is the URL for the running-config file:

**server** is the machine name (for example, "mymachine.myco.com").

**file-name** is the desired path name for the file. Lead with an extra slash (/) if the path is absolute: for example, "...myserver//var/configs/runConf" specifies /var/configs/runConf on "myserver." Use only one slash if the path is local to the server's "tftpboot" directory. This conforms with the specification for FTP URLs in RFC 1738.

**Syntax: Send in an Email**    `copy running-config smtp://[e-mail-address/]file-name`

**smtp://[e-mail-address/]file-name** (1-1024 characters) is an E-mail destination for the file:

**smtp://** is required. This declares that the destination is an E-mail address.

**e-mail-address** (optional) is the recipient of the E-mail in `username@host` format (for example, "jsmith@myco.com"). If you omit this, the CLI uses the default address set by the `cfg-smtp to` command.

**file-name** is the name of the running-config file. This is sent as an attachment to the outbound E-mail message.

You must configure SMTP on the ARX before you use this syntax. Start with the [smtp](#) command in `cfg` mode.

**Syntax: Local Copy** `copy running-config {configs | diag-info | scripts} file-name`

`configs | diag-info | scripts` is the destination directory. This is a required choice.

*file-name* (1-1024 characters) is a file name (for example, arxbeta02.cfg) to which you copy the switch's running-config information.

**Default(s)** None

**Guidelines** If you upload using SCP (a secure protocol), the CLI asks for a password. Provide a password for *user*. The user name and password must be valid at the SCP server. The CLI also prompts for a password if you use FTP and enter a *user* without a *password*.

Use this command to save the current running configuration to a file in the event you need to recreate the local configuration later. The `running-config` contains all of the parameters that you create under `cfg` mode, such as layer-2 and layer-3 configuration. These parameters apply only to the current switch, as opposed to a redundant peer. You should save a copy of the running config after any configuration change. To save the `running-config` on a regular schedule, you can use this command with the `at` command.

To copy global parameters to a file, such as namespaces and global servers, use the `copy global-config` command. To save both `running-` and `global-config` into a single file, use `copy startup-config`.

The `show running-config` command shows the config at the CLI prompt.

To recreate the running config (either on the same switch or a replacement switch), copy it to the `scripts` or `config` directory and use the `run scripts config-file-name` command.

Note that this command, `copy running-config`, immediately creates the `running-config` file from the database and then copies it, so its date stamp is either the time you invoked the command or the time that the file was created at the remote server. This is different from `copy configs boot-config`, which copies a file that was created when the system was installed: the `boot-config` file may have a time stamp with the system-install time.

**Samples** `bstnA# copy running-config config aco-run.cfg`  
copies the running config into the new "aco-run.cfg" file in the config directory.

`bstnA# copy running-config ftp://10.1.1.19/acopia-run.cfg`  
copies the running config to an FTP server at 10.1.1.19.

`bstnA# copy running-config smtp://jsmith@myco.com/ARX-run.cfg`  
sends the running config in an E-mail to "jsmith@myco.com."

`bstnA# copy running-config scp://juser@10.1.1.35:acopia-run.cfg`  
Password: `jpasswd`  
copies the running config to an SCP server at 10.1.1.35.

## copy startup-config

**Purpose** Use the `copy startup-config` command to copy the switch's full configuration (both running-config and global-config) to a specified directory and file. You can also use this command to upload the file to a remote server or send it in an E-mail message.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax: FTP Upload** `copy startup-config ftp://[user[:password]@]server/file-name`

`ftp://[user[:password]@]server/file-name` (1-1024 characters) is the syntax for uploading the startup-config:

`user[:password]@` (optional) are the credentials for FTP access. If you omit them altogether, they default to the credentials set by the `ip ftp-user` command. If you enter the `user` but omit the `password`, the CLI prompts for the password before continuing.

`server` is the IP address or hostname for the FTP server.

`file-name` is the destination-file path. Lead with an extra slash (“/”) if the path is absolute (for example, “ftp://10.1.1.5//var/cfgs/ac-start.cfg”). Use only one slash if the path is local to the home directory for `user` (for example, “ftp://10.1.1.5/ac-start.cfg”).

**Syntax: SCP Upload** `copy startup-config scp://user@server:dest-file [accept-host-key]`

`scp://user@server:dest-file` (1-1024 characters) is the URL for the destination file:

`user@` is the username to present to the other end of the SCP connection. This user must be valid at the remote host.

`server:` is the IP address or hostname for SCP host. End with a colon (:).

`dest-file` is the destination-file path. Lead with a slash (“/”) if the path is absolute (for example, “scp://root@10.1.1.5:/var/configs/startConf”). Use no slash if the path is local to the home directory for `user` (for example, “scp://root@10.1.1.5:mystart.cfg”).

**accept-host-key** (optional) indicates that if the other end of the connection has an unknown SSH host key (that is, if it is new, or if its key has changed since the last time the host was contacted), the ARX should accept the new host key and continue with the upload. Otherwise, the ARX stops the upload if the host presents an unknown key.

**Syntax: Sending to an ARX Volume** `copy startup-config {nfs|cifs} namespace vol file-name`

`nfs | cifs` is a required choice. This chooses the protocol for the file transfer.

`namespace` (1-30 characters) identifies the namespace to hold the startup-config file.

`vol` (1-1024 characters) is the volume name.

`file-name` (1-1024 characters) is the path to the config file, starting at the root of the volume.

---

**Syntax: Sending to Another ARX** `copy startup-config ron remote-arx {configs|scripts} file-name`

*remote-arx* (1-30 characters) is the [hostname](#) of the remote ARX to which you are sending the copy. This must be an ARX in the same Resilient-Overlay Network (RON); use [show ron](#) for a full list of hosts on the RON. The remote host checks your administrative credentials to confirm you have permission to copy the configuration file: the credentials are the [ip ron-user](#), or the credentials you used to log into the CLI if no RON user is set.

**configs | scripts** is the destination directory at the remote host. This is a required choice.

*file-name* (1-1024 characters) is a destination-file name, for example, strUpBstn.cfg, to which you copy/save the switch's startup-configuration information.

**Syntax: TFTP Upload** `copy startup-config tftp://server/file-name`

**tftp://server/file.tgz** (1-1024 characters) is the URL for the startup-config file:

*server* is the machine name (for example, "mymachine.myco.com").

*file-name* is the desired path name for the file. Lead with an extra slash (/) if the path is absolute: for example, "...myserver//var/configs/startConf" specifies /var/configs/startConf on "myserver." Use only one slash if the path is local to the server's "tftpboot" directory. This conforms with the specification for FTP URLs in RFC 1738.

**Syntax: Send in an E-Mail** `copy startup-config smtp://[e-mail-address]/file-name`

**smtp://[e-mail-address]/file-name** (1-1024 characters) is an E-mail destination for the file:

**smtp://** is required. This declares that the destination is an E-mail address.

*e-mail-address* (optional) is the recipient of the E-mail in *username@host* format (for example, "jsmith@myco.com"). If you omit this, the CLI uses the default address set by the [cfg-smtp to](#) command.

*file-name* is the name of the startup-config file. This is sent as an attachment to the outbound E-mail message.

You must configure SMTP on the ARX before you use this syntax. Start with the [smtp](#) command in [cfg](#) mode.

**Syntax: Local Copy** `copy startup-config {configs | diag-info | scripts} file-name`

**configs | diag-info | scripts** selects a local destination directory. You can [run](#) the file as a script later if you save it to the configs or scripts directory.

*file-name* (1-1024 characters) is a local-file name (for example, arxbeta02.cfg) to which you copy the switch's startup-config information.

**Default(s)** None

**Guidelines** If you upload using SCP (a secure protocol), the CLI asks for a password. Provide a password for *user*. The user name and password must be valid at the SCP server. The CLI also prompts for a password if you use FTP and enter a *user* without a *password*.

Use this command to save both the running-config and the global config to a file in the event you need to recreate the configuration. The running-config has all of the configuration parameters that apply to the current switch, and the global config has all the shared parameters for the redundant pair. To copy these configs individually, use `copy running-config` and/or `copy global-config`. After any configuration change, we recommend saving a copy of the changed configuration to an external server.

You can use this file later to recreate the full configuration, if necessary; copy it to the scripts directory and use the `run scripts config-file-name` command.

---

◆ **Note**

*A startup-config run changes the global config for both members of a redundant pair.*

To erase all configuration parameters and restart the configuration, you can delete the startup-config file (`delete startup-config`) and reboot (`reload`). This brings you back to the initial-boot script.

Note that this command, `copy startup-config`, immediately creates the startup-config file from the database and then copies it, so its date stamp is either the time you invoked the command or the time that the file was created at the remote server. This is different from `copy configs boot-config`, which copies a file that was created when the system was installed: the boot-config file may have a time stamp with the system-install time.

**Samples**

```
bstnA# copy startup-config config aco-startup.cfg
copies the startup config into the config directory.
```

```
bstnA# copy startup-config ftp://10.1.1.19/aco-start.cfg
copies the startup config to an FTP server at 10.1.1.19.
```

```
bstnA# copy startup-config scp://juser@10.1.1.19:aco-start.cfg
Password: jpasswd
copies the startup config to an SCP server at 10.1.1.19.
```

**Related Commands** [copy ftp](#)  
[copy scp](#)  
[copy {nfs|cifs}](#)  
[copy ron](#)  
[copy tftp](#)  
[copy smtp](#)  
[copy running-config](#)  
[copy global-config](#)  
[run](#)  
[ip ftp-user](#)  
[ip ron-user](#)  
[smtp](#)  
[delete startup-config](#)  
[show configs](#)  
[show running-config](#)

## delete startup-config

**Purpose** The startup-config contains all parameters in both the running config and the global config. When the switch starts up, it runs all of these CLI commands. Without this file, the switch has no network configuration (other than the OOB management interface) or global configuration (namespace, global servers, and so on). The only administrative users that remain are those with crypto-officer roles.

Use this command to delete the startup-config file.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `delete startup-config`

**Default(s)** None

**Guidelines** Before you delete the configuration, we recommend saving a copy with the [copy startup-config](#) command.

The CLI prompts for confirmation before deleting the startup-config file. Enter **yes** to continue.

After you delete the startup-config file, the chassis comes up from its next reboot with minimal configuration. You can use the [reload](#) command to invoke a reboot. Before the next reboot, you can use [restore startup-config](#) to recover a mistakenly-deleted startup-config.

Note that this deletes most of your network parameters, so you will only be able to log in through the OOB management port after reboot. To clear only namespaces, global servers, and other global parameters, you can use [clear global-config](#) instead.

To remove the remaining parameters and go back to the initial-boot script after the next reboot, you can also use [delete configs boot-config](#). This eliminates the OOB management port, too, requiring you to log in through the Console port after reboot.

**Sample** `bstnA# delete startup-config`

**Related Commands** [restore startup-config](#)  
[copy ftp](#)  
[copy scp](#)  
[copy {nfs|cifs}](#)  
[copy tftp](#)  
[copy startup-config](#)  
[show configs](#)  
[show running-config](#)  
[clear global-config](#)  
[delete configs boot-config](#)

---

## restore startup-config

**Purpose** The startup-config contains all parameters in both the running config and the global config. When the switch starts up, it runs all of these CLI commands. Without this information, the switch has no network configuration (other than the OOB management interface) or global configuration (namespace, global servers, and so on). The only administrative users that remain are those with crypto-officer roles. If the startup config was previously deleted, but no reboot has occurred since that delete, you can use this command to restore it.

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer, or crypto-officer

**Syntax** `restore startup-config`

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before restoring the startup-config file. Enter **yes** to continue.

This recreates the current configuration and expresses it as a series of CLI commands. You can use this command after you previously removed the startup-config with the [delete startup-config](#) command. This recovers from a mistakenly-deleted configuration. To confirm that the command was successful, you can use the [show configs](#) command and confirm that a new “startup-config” entry is in the listing.

If you run [delete startup-config](#) and [reload](#) before running this command, the chassis boots up without any configuration parameters. The `restore startup-config` command is no-longer useful after the chassis reboots.

**Sample** `bstnA# restore startup-config`

```
Restore file 'startup-config' in directory 'configs'? [yes/no] yes
```

**Related Commands** [delete startup-config](#)  
[show configs](#)  
[copy startup-config](#)

## save boot-config

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | The boot-config file contains all of the parameters that are set by the initial-boot script (described in the <i>Hardware Installation Guides</i> ). If this file is absent when the switch boots, the switch reruns this script. Use the <b>save boot-config</b> command to ensure that the switch keeps its boot-config for the next reboot.                                                                                                                                                                                                                                                                                                                                                     |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Security Role(s)</b> | network-technician, network-engineer, storage-engineer, or crypto-officer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Syntax</b>           | <b>save boot-config</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default(s)</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Guidelines</b>       | After you delete the boot-config file (with <a href="#">delete configs boot-config</a> ) and reboot, the Console goes to the initial-boot script (described in the <i>Hardware Installation Guides</i> ). The CLI starts after you answer all of the questions in the initial-boot script. This command prevents re-running the initial-boot script. It creates a text file named “boot-config,” which you can see with the <a href="#">show configs</a> command. You can use the copy command ( <a href="#">copy ftp</a> , <a href="#">copy scp</a> , <a href="#">copy {nfs/cifs}</a> , or <a href="#">copy tftp</a> ) to upload it to an external host, or to download a new boot-config script. |
| <b>Sample</b>           | bstnA# <b>save boot-config</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Related Commands</b> | <a href="#">delete configs boot-config</a><br><a href="#">show configs</a><br><a href="#">copy ftp</a><br><a href="#">copy scp</a><br><a href="#">copy {nfs/cifs}</a><br><a href="#">copy tftp</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

---

# show global-config

**Purpose** Use the `show global-config` command to view an ordered list of CLI commands required to recreate the current global-config state.

**Mode** (any)

**Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator

**Syntax**

```
show global-config
show global-config [filer|global-server|schedule|security|
 config-replication]
show global-config archive [file-history-archive]
show global-config {nfs|cifs} [fqdn]
show global-config namespace [name [volume]]
```

**filer** | **global-server** | **policy** | **security** | **config-replication** are optional choices to focus on one section of the global-config report.

**filer** specifies external-filer details.

**global-server** specifies global-server configurations.

**schedule** specifies policy schedules.

**security** specifies security information such as management services authentication providers.

**config-replication** focuses the output on [config-replication](#) rules.

**archive** is an optional choice to focus on the “archive” section of the global-config report. This section has the configuration for every [file-history archive](#) on the ARX. Unless you specify a particular *file-history-archive* name, this shows the configurations for all of them.

*file-history-archive* (optional, 1-64 characters) identifies a particular archive.

**nfs** | **cifs** specifies that you want to focus on NFS or CIFS services only. Unless you include an *fqdn*, this shows all front-end services of the given type.

*fqdn* (optional, 1-128 characters) identifies a particular NFS or CIFS service (for example, “www.medarcv.com”). For a list of all NFS and CIFS services, use the [show virtual service](#) command.

**namespace** specifies that you want to focus on namespaces only. If you omit the *name*, all namespaces are shown.

*name* (optional, 1-30 characters) identifies a particular namespace (for example, “medarcv”). Use [show namespace](#) for a list of all namespaces.

*volume* (optional, 1-1024 characters) identifies a particular namespace volume (for example, “/usr”).

**Default(s)** None

- Guidelines** The output appears in table format by sections. The sections correspond to groups of commands for setting up major portions of the global configuration (such as namespaces, global servers, filers, policy, security, and so on).
- The *global-config* parameters are shared among both peers in a redundant pair; they do not include parameters that apply to the current switch only. For parameters that apply to the local switch, such as layer 2 and 3 parameters, use [show running-config](#).
- After changes to the configuration, we recommend using [copy global-config](#) to save this text off to a file.
- Later, to recreate a saved global-config, paste the text at the CLI prompt (from priv-exec mode) or [copy](#) the file from a remote server and use the [run](#) command to run it as a script.
- Passwords and private SSH keys appear in encrypted form. Only the current switch (or a replacement for the current switch) can interpret and use this private information.

◆ **Note**

---

*A global-config run changes the global config for both members of a redundant pair.*

- Samples** bstnA> [show global-config](#)  
shows the full global-config. [Figure 33.1](#) shows a sample report.
- bstnA> [show global-config filer](#)  
shows all filer-configuration settings. See [Figure 33.2 on page 33-36](#) for sample output.
- bstnA> [show global-config namespace wwmed](#)  
shows the CLI commands to recreate one namespace, wwmed. See [Figure 33.3 on page 33-38](#) for sample output.
- bstnA> [show global-config cifs](#)  
shows all configuration settings for all front-end-CIFS services.

- Related Commands** [copy ftp](#)  
[copy scp](#)  
[copy {nfs|cifs}](#)  
[copy tftp](#)  
[copy global-config](#)  
[show running-config](#)  
[show virtual service](#)  
[show namespace](#)

*Figure 33.1 Sample Output: show global-config*

```
bstnA> show global-config
; ARX-4000
; Version 6.03.000.14755 (Jun 15 2012 20:15:33) [nbuilds]
; Database version: 603000.1
; Generated global-config Wed Jun 20 01:43:32 2012
;
terminal character-set unicode-utf-8
```

| <b>Purpose</b>          | The running-config applies to the local switch only; these parameters are not shared with the redundant peer. Use the <code>show running-config</code> command to view an ordered list of CLI commands required to recreate the current running-config state.                                                                                                                                                                                              |
| <b>Mode</b>             | (any)                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Security Role(s)</b> | crypto-officer, storage-engineer, network-engineer, network-technician, or operator                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Syntax</b>           | <code>show running-config</code>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Guidelines</b>       | <p>The output is interspersed with comments that break it into sections. Each section is labeled in the comment. You can use <a href="#">copy running-config</a> to save this text off to a file, or upload it to an FTP server.</p> <p>The running-config parameters all apply to the current switch only. For parameters that are shared between redundant peers, such as namespace parameters, use <a href="#">show global-config</a>.</p>              |
| <b>Sample</b>           | <pre>bstnA&gt; show running-config</pre> <p>shows the running-config. <a href="#">Figure 33.4</a> shows a sample report on an ARX-4000, <a href="#">Figure 33.5 on page 33-47</a> shows a sample report on an ARX-2500, <a href="#">Figure 33.6 on page 33-52</a> shows an ARX-2000 sample, <a href="#">Figure 33.7 on page 33-57</a> shows an example from an ARX-500, and <a href="#">Figure 33.8 on page 33-63</a> shows an example from an ARX-VE.</p> |
| <b>Related Commands</b> | <a href="#">copy ftp</a><br><a href="#">copy scp</a><br><a href="#">copy {nfs cifs}</a><br><a href="#">copy tftp</a><br><a href="#">copy running-config</a><br><a href="#">show directories</a><br><a href="#">show chassis</a><br><a href="#">show global-config</a>                                                                                                                                                                                      |

## ARX API and Notification Rules

---

---

---

## clear statistics api

**Purpose** The ARX supports a SOAP-based API for monitoring general configuration, usage statistics, and specific file and directory changes in its managed volumes. You can use the [show statistics api](#) command to show the usage statistics for this API. This command, `clear statistics api`, resets all of the statistical counters to 0 (zero).

**Mode** priv-exec

**Security Role(s)** network-technician, network-engineer, storage-engineer or crypto-officer

**Syntax** `clear statistics api`

**Default(s)** None

**Guidelines** The [show statistics api](#) command shows cumulative statistics for API usage. Use this command to clear those statistical counters.

The CLI prompts for confirmation before clearing any statistics; type **yes** to proceed.

**Sample**  
provA# `clear statistics api`  
Clear API statistics? [yes/no] **yes**

**Related Commands** [show statistics api](#)

## clear statistics notification

**Purpose** A *notification rule* is required to support the SOAP-based API for its managed volume. This rule takes regular snapshots, or point-in-time copies, of a volume's files and metadata. These are called *notification snapshots*, and managed volumes keep statistics on them. Use this command to clear the cumulative statistics for a particular notification rule.

**Mode** priv-exec

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **clear statistics notification *namespace* *volume* *notification-rule***

*namespace* (1-30 characters) identifies a namespace.

*volume* (1-1024 characters) is a volume that supports notification snapshots.

*notification-rule* (1-1024 characters) is the rule whose statistics should be cleared.

**Default(s)** None

**Guidelines** The CLI prompts for confirmation before clearing any notification-snapshot statistics. Enter **yes** to proceed.

The [show policy ... details](#) command shows cumulative statistics for notification-snapshot operations. Use this command to clear the statistical counters for one notification rule.

**Sample** provA# **clear statistics notification provMed /mds mdChgs**

Confirming this command causes all historic statistical data for the snapshot rule to be reset.

Proceed? [yes/no] **yes**

clears all notification statistics for the "mdChgs" rule.

**Related Commands** [show policy](#)

---

## enable (gbl-ns-vol-ntfy)

**Purpose** A *notification rule* is required to support a SOAP-based API for the current volume. This rule takes regular snapshots, or point-in-time copies, of the volume's files and metadata. The volume can use these snapshots to answer procedure calls from the API's clients.

Use the **enable** command to enable the current notification rule. The rule must be enabled to create any ARX snapshots, either manually or by a schedule. It also must be enabled to track file changes in real time.

Use **no enable** to disable the current notification rule.

**Mode** gbl-ns-vol-ntfy

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **enable**  
**no enable**

**Default(s)** **no enable**

**Guidelines** You must enable a rule for the policy engine to use it, or to invoke it manually with [snapshot create](#).

**Samples** `provA(gbl-ns-vol-ntfy[provMed~/mds~mdChgs])# enable`  
enables the current notification rule.

`provA(gbl-ns-vol-ntfy[provMed~/rns~testNtfy])# no enable`  
disables the "testNtfy" rule in the same namespace.

**Related Commands** [namespace](#) -> [volume](#) -> [notification rule](#)  
[snapshot create](#)

## notification rule

**Purpose** The ARX supports a SOAP-based API for monitoring its configuration and usage. A client application can use this API to query a managed volume about changes in its files and directories over time. To respond to these queries, the managed volume must keep regular snapshots of its metadata as well as its actual files. The managed volume can compare these snapshots to discover creates, deletes, renames, and changes in any given file or directory. You use the **notification rule** command to begin the process of taking regularly-scheduled snapshots for this purpose.

Use the **no** form of the command to remove the notification rule without removing any of the snapshots behind it.

**Modes** gbl-ns-vol

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **notification rule** *name*  
**no notification rule** *name*

*name* (1-1024 characters) is a name you choose for the notification rule.

**Default(s)** None

**Guidelines: Filer Preparation** Before you begin, you must prepare all the filers behind the volume. The volume must be backed by NetApp filers, EMC Celerra servers, EMC Data Domain systems, and/or Windows servers that support snapshots. In the case of Windows servers, WinRM must also be installed so that the ARX can invoke snapshots through its management API.

The filer that holds the volume's [metadata share](#) must also support snapshots.

The ARX volume creates a notification snapshot by issuing CLI commands to each of its back-end filers, including the filer used for the metadata share. The ARX therefore needs information and credentials for accessing each filer's CLI. From gbl-filer mode, use the [filer-type](#) command to identify the filer vendor, use [proxy-user \(gbl-filer\)](#) to identify a proxy user with proper management-login credentials, and use [manage snapshots](#) to declare that the filer supports snapshots. You can use the [ip address ... management](#) command to designate the management-IP address at that station (by default, the ARX logs into the CLI through an external filer's primary-IP address, set with the simplest syntax for the [ip address](#) command).

---

◆ **Note**

*All of the filers behind the managed volume, including the one that contains the volume's [metadata share](#), must support snapshots. The notification rule requires a full set of snapshots so that it can support specific API queries about any file in the volume. This rule does not support "sparse" snapshots, where some back-end shares are excluded. Configure all of the volume's external filers as described above.*

**Guidelines** An enabled notification rule is the basis for supporting file-change queries in the ARX API. You apply a schedule to the rule so that it takes regular snapshots, and you can also invoke the rule manually with the [snapshot create](#) command.

When you create a new notification rule, the CLI prompts for confirmation. Enter **yes** to create the rule. (You can use [terminal expert](#) to eliminate confirmation prompts for creating new policy objects.)

This command places you in `gbl-ns-vol-ntfy` mode, where you enable the rule and where you have some options that you can apply to it. By default, a notification rule retains three snapshots; whenever it successfully creates a new snapshot, it deletes the oldest snapshot so that there are never more than three. You can use the optional [retain \(gbl-ns-vol-ntfy\)](#) command to change the number of retained snapshots. A notification rule requires a regular schedule, which you set with the [schedule \(gbl-ns-vol-ntfy\)](#) command. To enable report-generation for each snapshot, use the [report \(gbl-ns-vol-ntfy\)](#) command. You must use the [enable \(gbl-ns-vol-ntfy\)](#) command to enable this rule to take any snapshots at all, even manually. You cannot exclude any storage shares in the managed volume; a notification rule requires that all storage shares in the volume support snapshots. The snapshots automatically exclude any shares with the special [replica-snap](#) setting.

You cannot configure a notification rule in a direct volume. A notification rule requires snapshots of the volume's metadata, and direct volumes do not have any metadata.

**Guidelines: API** To activate the ARX API, use the [management access \[http-api | https-api\]](#) command followed by the [permit](#) command. This opens a port where a SOAP client can send queries to this volume. The HTTP-API port is 83, and the HTTPS-API port is 843.

Use the following URL syntax to access the API documentation through HTTP:

**http://*arx-management-ip*:83/arx-api/**

where *arx-management-ip* is either the out-of-band management-IP address ([interface mgmt](#)) or an in-band (VLAN) management-ip address ([interface vlan](#)). The [permit](#) command determines which of these address types are available for access. Use [show interface mgmt](#) and/or [show interface vlan](#) to find the IP addresses for each interface.

This URL accesses the same documentation through HTTPS:

**https://*arx-management-ip*:843/arx-api/**

where *arx-management-ip* is a valid management IP, as described above.

You can use the [show statistics api](#) command to find usage statistics for the API.

**Guidelines: Managing Notification Snapshots**

You can use [snapshot manage](#) to incorporate existing filer snapshots into the notification rule, but you cannot use it for any metadata snapshots. The command is therefore not recommended for notification rules.

Each ARX snapshot has one or more component snapshots on its back-end filers. You can use the [snapshot verify](#) command to verify that all of the component snapshots still exist behind a notification rule. This does not check the snapshot on the metadata share.

To see the current state of notification-related snapshots, use the [show notification](#) command.

**Guidelines: VIP Fencing** During a snapshot-create operation, clients can access the volume and possibly make changes, rendering the filer snapshots inconsistent from one another. This inconsistency creates challenges for API clients: it could, in rare cases, affect queries about file content or file attributes. This has no effect on queries about creates, deletes, or renames, which are all derived from the metadata snapshot.

For sites where these queries are particularly important, you can use the [snapshot consistency](#) command to put up a *VIP fence* for snapshots. This fence prevents client access to any VIP that supports this volume. This may affect multiple volumes. The fence stays up until the last filer completes its snapshot or checkpoint, or until a timeout expires.

**Guidelines: Snapshot Presentation to Clients** By default, CIFS clients can access their snapshots with Windows Explorer. They select a file or directory, pull up its **Properties**, and find a list of snapshots for the file or directory in the **Previous Versions** tab. CIFS clients can use this interface to find and restore previous versions of their files and directories. Microsoft calls this the Volume Shadowing Service, or *VSS*, for Shared Folders.

NFS clients typically access their snapshots through a “.snapshot” directory that appears in every directory in the ARX volume.

Refer to the Guidelines for the [snapshot rule](#) command to learn about CLI commands that can affect the client view of snapshots.

**Guidelines: Filer-Snapshot Names** Each EMC or NetApp snapshot has a unique name to distinguish it as a backing snapshot for a particular ARX. The snapshot names use the following format

```
acopia_id_time-stamp_uuid_filer-volume
```

where

- *id* is an integer that the snapshot software uses internally.
- *time-stamp* is in *yyyymmddHHMM* format. This is the time that the snapshot was created.
- *uuid* is the Universally-Unique ID that identifies the ARX. In a redundant pair, this is the UUID for the peer that was originally configured as senior/active, no matter which peer is currently active. You can find an ARX’s UUID in the output of [show running-config](#).
- *filer-volume* is the name of the filer’s volume.

Windows servers use a UUID in curly braces ({} ) to identify each snapshot. This does not change for ARX-generated snapshots.

**Guidelines: Configuration Changes in a Scheduled Rule** If you make a configuration change in a notification rule that is running with a schedule, the configuration change is ineffective until the next time the rule runs.

**Guidelines: Removing the Notification Rule** The `no` form of the command removes the rule without removing any snapshots from the back-end filers. To remove the snapshots from the filers, use the [snapshot remove](#) command *before* you remove the rule. This is an efficient method for cleaning all of the supporting snapshots behind the rule. If supporting snapshots remain when you invoke `no notification rule`, the CLI lists all remaining snapshots when it prompts for confirmation.

The [snapshot remove](#) command removes snapshots from all the storage-share filers; you must manually remove snapshots from your metadata-share filer.

---

**Guidelines: Snapshot Reconstitution**

Snapshot Reconstitution is not supported for notification rules. Refer to the Guidelines for the [snapshot rule](#) command to learn about snapshot reconstitution.

**Samples**

```
provA(gbl-ns-vol[provMed~/mds])# notification rule mdChgs
This will create a new policy object.
```

```
Create object 'mdChgs'? [yes/no] yes
provA(gbl-ns-vol-ntfy[provMed~/mds~mdChgs])# ...
instantiates a new notification rule, "mdChgs," in the current namespace volume.
```

```
bstnA(gbl-ns-vol[medarcv~/lab_equipment])# no notification rule apiTst
```

The following snapshots are being managed by the rule 'apiTst':

```
apiTst_0(acopia_27_200707170500_501f705c-8735-11d8-8936-a58a9e4556df_d
atavol2)
```

```
apiTst_2(acopia_25_200707170300_501f705c-8735-11d8-8936-a58a9e4556df_d
atavol2)
```

```
apiTst_1(acopia_26_200707170400_501f705c-8735-11d8-8936-a58a9e4556df_d
atavol2)
```

If this command is confirmed, the rule is deleted and all associated data related to the aforementioned snapshots will be removed from the switch. The snapshots on the filers will not be removed.

```
Proceed? [yes/no] yes
bstnA(gbl-ns-vol-snap[medarcv~/lab_equipment])# ...
removes a notification rule with some existing snapshots remaining on one of its
back-end filers.
```

## report (gbl-ns-vol-ntfy)

**Purpose** A *notification rule* is required to support a SOAP-based API for the current volume. Use this command to enable progress reports for the current notification rule. Use `no report` to prevent progress reports.

**Mode** gbl-ns-vol-ntfy

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `report file-prefix`  
`no report`

*file-prefix* (1-1024 characters) sets a prefix for all notification reports. Each report has a unique name in the following format:

*file-prefix\_0\_create\_YearMonthDayHourMinuteSecondsMilliseconds.rpt*

For example, `md_chgs_0_create_20110823031645354.rpt` could be the name for one report with the prefix, “md\_chgs.”

**Default(s)** `no report`

**Guidelines** Every time a notification rule fires and creates a coordinated snapshot, the rule can generate a report to show the details of the snapshot-create operation. This includes details about each snapshot at each of the volume’s back-end filers. The reporting feature is disabled by default; we recommend that you enable reporting for all notification rules, to diagnose any problems that occur with its snapshots.

Use [show reports](#) for a list of reports, or `show reports file-name` to show the contents of one report.

See [Figure 34.1 on page 34-11](#) for a sample snapshot-create report.

**Sample** `provA(gbl-ns-vol-ntfy[provMed~/mds~mdChgs])# report md_chgs`  
enables reports for the snapshot rule, “mdChgs.”

**Related Commands** [namespace](#) -> [volume](#) -> [notification rule](#)  
[show reports](#)

**Figure 34.1** Sample Report: *md\_chgs\_0\_create\_....rpt*

```
provA# show reports md_chgs_0_create_20120307023703404.rpt

## retain (gbl-ns-vol-ntfy)

**Purpose** A *notification rule* is required to support a SOAP-based API for the current volume. Each notification rule retains some maximum number of *snapshots*, or point-in-time copies, of its volume's files and metadata. Use this command to set the number of retained snapshots for the current rule.

Use **no retain** to revert to the default retention count.

**Modes** gbl-ns-vol-ntfy

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** **retain** *snap-count*  
**no retain**

*snap-count* (1-1024) is the maximum number of snapshots for this rule to retain.

**Default(s)** 3

**Guidelines** Whenever the notification rule runs, it creates a new snapshot "0" (zero). The former snapshot "0" becomes snapshot "1," the former snapshot "1" becomes snapshot "2," and so on. The rule deletes the oldest snapshot if keeping it would exceed the retain count. For example, if the rule retains 5 snapshots, it only keeps snapshots 0-4. It removes the older snapshots from client presentations as well as the back-end filers. Additionally, the API clients cannot use these removed snapshots. This prevents wasted snapshot space on the filers.

If you increase the retention count in a rule that already has a full count of snapshots, the rule does not delete any snapshots until it exceeds the count again. For example, if the retain count increases from three to four, the next time the rule runs it moves snapshot "3" to "4" and does not delete any snapshots. On the following run of the rule, it deletes snapshot "4" to avoid exceeding the retain count.

If you decrease the retain count in a rule that has already reached it, the volume removes all excess snapshots the next time the rule runs.

**Sample** `provA(gbl-ns-vol-ntfy[provMed~/mds~mdChgs])# retain 31`  
retains 31 snapshots for the rule named "mdChgs."

**Related Commands** [namespace](#) -> [volume](#) -> [notification rule](#)

## schedule (gbl-ns-vol-ntfy)

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Syntax</b>                        | <p><code>schedule <i>name</i></code><br/><code>no schedule</code></p> <p><i>name</i> (1-64 characters) identifies the schedule. Use <code>show schedule</code> for a list of configured schedules.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Default(s)</b>                    | None.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Guidelines</b>                    | <p>A notification rule takes <i>snapshots</i> (point-in-time copies) of an ARX volume on a regular schedule. This command determines which schedule to use.</p> <p>You can also manually invoke the rule's snapshots with the <code>snapshot create</code> command.</p> <p>To create a schedule, use the gbl-mode <code>schedule</code> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Guidelines: Snapshot Grouping</b> | <p>If more than one snapshot-producing rule (<code>snapshot rule</code>, <code>snapshot replica-snap-rule</code>, and/or <code>notification rule</code>) uses the same schedule, the ARX aggregates all of the filer snapshots at once. This is called <i>snapshot grouping</i>. By grouping the filer snapshots, the ARX avoids any duplicate snapshots on a given back-end volume.</p> <p>Snapshot grouping may create a problem for volumes backed by EMC Celerra servers, which serialize their snapshots. Consider a site with 10 volumes backed by 10 different back-end volumes on a single EMC server. If all 10 ARX volumes use the same snapshot schedule, each ARX snapshot must wait for all 10 EMC checkpoints to finish, one after the other.</p> <p>Each ARX volume must use the same schedule (by name) for snapshot grouping to occur. If you use schedules with different names but the same dates and times, the ARX volumes independently perform their snapshot operations. This could result in duplicate snapshots on the same back-end volume, but it avoids the EMC-serialization issue.</p> |
| <b>Sample</b>                        | <pre>provA(gbl-ns-vol-ntfy[provMed~/mds~mdChgs])# schedule oncePerDay</pre> <p>uses a schedule named "oncePerDay" for the "mdChgs" notification rule.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## show notification

**Purpose** A *notification rule* is required to support a SOAP-based API for the current volume. Use the `show notification` command to see the current status of one or more notification rules.

**Mode** (any)

**Security Role(s)** backup-operator or crypto-officer

**Syntax** `show notification`  
`show notification namespace ns`  
`show notification namespace ns volume path`  
`show notification namespace ns volume path rule rule-name`

*ns* (1-30 characters) identifies the namespace with the notification rule(s).

*path* (1-1024 characters) focuses on one volume in the namespace.

*rule-name* (1-1024 characters) focuses on one notification rule. This changes the output to a detailed view of the rule.

**Guidelines: Summary View**

The simplest output shows a summary of all selected *snapshots*, or point-in-time copies of an ARX volume. This is a table with one line per snapshot. Each line contains the following fields:

Namespace,

Volume, and

Rule all identify the notification rule.

**Name** is the name of the particular notification snapshot. This is typically the rule name with an integer ID that indicates the order of these snapshots (“0” is the newest, “1” is the next-newest, and so on).

**Status** indicates the result of the coordinated snapshot:

- **Requested** means that someone issued a [snapshot create](#) command, or that the rule’s schedule just invoked a new snapshot.
- **In Progress** indicates that a snapshot is currently underway at the back-end filers.
- **Created** means that all filer snapshots were created successfully.
- **Created (Sparse)** means that one or more filer snapshots failed. This indicates that the notification snapshot is invalid. All filers behind the volume, including the filer used for metadata, must have the [manage snapshots](#) setting for notification snapshots to succeed.
- **Incomplete** means that the fencing timeout expired before the snapshot finished on all of its included back-end filers. This implies that [snapshot consistency](#) is enabled, causing the volume’s VIP(s) to put up a *fence* against client access until the snapshots finish.
- **Fence failed** also implies that [snapshot consistency](#) is enabled, and means that the VIP failed to raise its fence against client access. This indicates an internal-software error; contact F5 Support if you see this.

**Guidelines: Summary  
View (Cont.)**

- Policy pause failed indicates another internal-software error, and should not appear during normal operation. As above, contact F5 Support if you see this.
- Failed indicates that the snapshot operation failed at one or more back-end filers or servers. Check the snapshot report (available in the detailed output) for more details.

Time Created indicates the time when the final filer finished its snapshot.

Source is “Schedule” or “Manual.”

- Schedule indicates that the snapshot was invoked by the notification rule’s [schedule \(gbl-ns-vol-ntfy\)](#), and
- Manual means that an administrator manually invoked a snapshot with the [snapshot create](#) command.

**Guidelines:  
“Snapshot Summary”  
in Detailed View**

The detailed view of a notification rule appears when you specify the rule in the command. This shows two tables: “Snapshot Summary” and “Snapshot Properties.”

The “Snapshot Summary” table summarizes the rule configuration:

Namespace Name,

Volume Name, and

Snapshot Rule Name are defined by the [notification rule](#) command.

**Guidelines:  
“Snapshot  
Properties”**

The “Snapshot Properties” Table provides details about the snapshot configuration:

Snapshots Enabled is “Yes” or “No,” depending on the setting for [enable \(gbl-ns-vol-ntfy\)](#).

Guarantee Consistency is “Enabled” or “Disabled,” depending on whether or not the volume uses VIP fencing for its snapshots. The VIP fence, if enabled, blocks all client access to the volume while the filers take their coordinated snapshots. Use the [snapshot consistency](#) command to allow or disallow this fence.

Retain Count is the number of snapshots to retain for this rule. If the rule has this many snapshots when it takes a new one, it moves all of the snapshots to the next slot down and then deletes the oldest snapshot. For example, it creates a new “rnChgs\_0” snapshot, moves the old “rnChgs\_0” to “rnChgs\_1,” and so on, until it reaches the retain count; then it deletes any remaining snapshots. You can control this with the [retain \(gbl-ns-vol-ntfy\)](#) command.

Schedule is the name of the schedule for the notification rule, if any. Use the [schedule \(gbl-ns-vol-ntfy\)](#) command to assign a schedule to the snapshot rule.

CIFS Directory Name only appears if the volume supports CIFS. This is the pseudo directory that well-informed CIFS clients (administrators) can use to access their snapshots. You can use the [snapshot directory cifs-name](#) command to change this name.

NFS Directory Name only appears if the volume supports NFS. This is the pseudo directory that well-informed NFS clients (administrators) can use to access their snapshots. You can use the [snapshot directory nfs-name](#) command to change this name.

Directory Display is “All Exports” (clients see the ~snapshot/.snapshot directory in any front-end share), “Volume Root Only” (clients only see the directory only in a front-end share of the volume’s root directory) or “None.” You can use the [snapshot directory display](#) command to change this.

---

**Guidelines:  
“Snapshot  
Properties” (Cont.)**

**Hidden File Attribute** only appears if the rule’s volume supports CIFS. This is “Set” if the special ~snapshot directory has its “hidden” DOS attribute raised, or “Not Set” otherwise. Use an optional argument in the [snapshot directory display](#) command to control this setting. This option is irrelevant to NFS clients.

**Restricted Access Configured** also only appears if the volume supports CIFS. This is “Yes” or “No” depending on whether or not someone used the [snapshot privileged-access](#) command. If this is “Yes,” a small set of privileged CIFS clients can access the volume’s snapshots. These clients are members of a Windows-Management-Authorization (*WMA*) group with permission to monitor snapshots. These privileged clients are typically administrators. This option has no impact on NFS clients.

**VSS Mode** only appears if the volume supports CIFS. This field indicates the client-machine versions for which the volume supports the Volume Shadow-copy Service (*VSS*). *VSS* is an intuitive interface that Windows clients can use to access their snapshots. This is “Windows XP” (the volume supports *VSS* for Windows XP client machines, as well as newer machines), “Pre-Windows XP” (the volume also supports *VSS* for Windows-2000 clients), or “None.” Use the [snapshot vss-mode](#) command to change this setting. As above, this option has no impact on NFS clients.

**Guidelines:  
“Snapshot Summary -  
snapshot-name”**

After the notification rule has run at least once, additional tables appear for each of its snapshots. The first table, “Snapshot Summary - *snapshot-name*” summarizes the notification snapshot. This table contains the following fields:

**Snapshot Name** is the name of the notification snapshot.

**Time Requested** is the last date and time that someone issued an ARX command (such as [snapshot create](#) or [snapshot verify](#)) for this notification snapshot.

**Time Created** shows the date and time that the last filer behind the volume completed its snapshot or checkpoint operation. “In progress” appears if a snapshot is currently underway.

**Last Time Verified** is the last time someone ran [snapshot verify](#) against this notification snapshot.

**Guidelines:**  
**“Snapshot Summary -  
snapshot-name”**  
**(Cont.)**

Request shows the currently-active request for this ARX snapshot. This is one of the following:

- **Idle** indicates that no command is currently running on this snapshot.
- **Create** means the rule is currently creating a notification snapshot. This indicates either a scheduled snapshot or a snapshot invoked by the [snapshot create](#) command.
- **Manage** shows that the rule is incorporating an existing snapshot to an ARX snapshot. This means that someone invoked the [snapshot manage](#) command.
- **Delete** indicates that filer snapshots are being removed from behind this rule. This request comes from the [snapshot remove](#) command.
- **Remove** indicates that someone invoked [no notification rule](#) to delete the current notification rule.
- **Verify** shows that someone invoked [snapshot verify](#) to verify the integrity of all filer snapshots behind this notification snapshot.
- **Cleanout** indicates that a notification snapshot failed and the snapshot software is removing filer snapshots that are inconsistent with one another. This should be rare. If you see this, you can use the [show cores](#) command to check for core-memory files from the snapshot software. The clean-out operation generates a snapshot report that you can see with the [show reports](#) command.

**Snapshot State** shows the results of the most-recent snapshot operation. This is either “Complete” or “Incomplete.” “Complete” indicates a successful snapshot on all of the volume’s shares. An “Incomplete” state only applies to a [snapshot verify](#) operation: this indicates that one of the included shares is now missing its back-end snapshot or checkpoint.

**Snapshot Origin** is “Schedule” or “Manual.” This has the same possible values as the **Source** field in the summary view:

- **Schedule** indicates that the snapshot was invoked by the notification rule’s [schedule \(gbl-ns-vol-ntfy\)](#), and
- **Manual** means that an administrator manually invoked a snapshot with the [snapshot create](#) command.

**Report Name** identifies the report for the rule’s most-recent action. You can use [show reports report-name](#) to view this report.

**Guidelines: “Included  
Shares”**

A separate table appears under the “Included Shares” heading for each of the shares in this snapshot. These describes the component snapshots for the notification snapshot described above. Each table contains the following fields to describe the snapshot on a particular filer:

**Share Name** is the name of the share in the ARX volume, defined by the [share](#) command.

**Filer** is a header for the remaining fields.

**Name** is the external-filer name, defined with the [external-filer](#) command.

**NFS Share** is the name of the NFS export at the filer.

**CIFS Share** is the name of the share at the filer.

**Volume** is the name of the filer volume behind the above filer share.

**Volume Snapshot** is the name of the filer snapshot.

**Guidelines: “Excluded Shares” and “Offline Shares”**

If any of the volume’s shares were administratively excluded from the snapshot, an “Excluded Shares” section appears to describe them. You can use `no manage snapshots` to exclude all shares on a filer. A notification rule requires that all storage shares are in every snapshot, so this causes the notification snapshot to fail. These tables contain the same fields that are in the “Included Shares” tables, except the fields to describe the back-end snapshot.

If the snapshot operation failed at any of the volume’s back-end share, an “Offline Shares” section appears to describe them. These share tables contain the same fields as those in the “Excluded Shares” section.

**Samples**

`provA# show notification`

shows a summary of all notification snapshots on the ARX. See [Figure 34.2](#), below, for sample output.

`provA# show notification namespace provMed volume /mds rule mdChgs`

shows details for the “mdChgs” rule. See [Figure 34.3 on page 34-19](#) for sample output.

| <b>Purpose</b>                                                      | The ARX supports a SOAP-based API for monitoring configuration and usage. A client application can also use this API to query a managed volume about changes in its files and directories over time. Use the <code>show statistics api</code> command to see statistics for the usage of this API.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Guidelines</b>                                                   | <p>The output is a two-column table showing the number of calls to each of the API's supported functions. The functions are separated into the following major categories:</p> <ul style="list-style-type: none"> <li><b>API</b> is a generalized category with meta information about the API itself.</li> <li><b>Chassis</b> contains the procedure calls for information about the hardware chassis, and possibly its redundant peer.</li> <li><b>Export</b> is a group of procedures related to front-end-CIFS shares (see <a href="#">export (gbl-cifs)</a>) and front-end-NFS exports (<a href="#">export (gbl-nfs)</a>) on the ARX.</li> <li><b>FileChangeNotification</b> is a set of procedures for finding out about file changes in a managed volume. These procedures access the snapshots produced by a <a href="#">notification rule</a> (see the <i>Guidelines</i> below).</li> <li><b>FileServer</b> is a group of procedures related to <a href="#">external-filers</a> behind the ARX.</li> <li><b>ManualMigrateRule</b> is a group of procedures for migrating files from one back-end filer to another behind a managed volume.</li> <li><b>Namespace</b> is the heading for procedures related to <a href="#">namespaces</a> on the ARX.</li> <li><b>Network</b> is a group of procedures related to network configuration and statistics.</li> <li><b>Policy</b> is a group of procedures related to policy configuration, including <a href="#">schedules</a>.</li> <li><b>Report</b> is the heading for report-access procedures. These allow an API client to access the same reports you can see with <a href="#">show reports</a>.</li> <li><b>Schedules</b> is a group of procedures for creating, editing, and viewing ARX <a href="#">schedules</a>.</li> <li><b>Share</b> contains procedure calls related to <a href="#">shares</a> on the ARX.</li> <li><b>VirtualService</b> is a group of procedures related to <a href="#">global servers</a>, <a href="#">virtual servers</a>, <a href="#">cifs</a> services, and <a href="#">nfs</a> services on the ARX.</li> <li><b>Volume</b> contains procedure calls related to <a href="#">volumes</a> on the ARX.</li> </ul> <p>The statistics clear whenever the chassis reboots. You can use the <a href="#">clear statistics api</a> command to clear them manually.</p> |
| <b>Guidelines: Setting Up File-Change Notifications for the API</b> | <p>The procedure calls under <b>FileChangeNotifications</b> require some preparation. For each managed volume where you want to track file changes, create a <a href="#">notification rule</a>. This rule creates snapshots of the volume's metadata and all of its shares. The API monitors the volume over time, and it probes these snapshots as needed to fulfill its procedure calls.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Guidelines: API** To activate the ARX API, use the [management access](#) command followed by the [permit](#) command. This opens a port where a SOAP client can send queries to this volume. The HTTP-API port is 83, and the HTTPS-API port is 843.

Use the following URL syntax to access the API documentation through HTTP:

**http://arx-management-ip:83/arx-api/**

where *arx-management-ip* is either the out-of-band management-IP address ([interface mgmt](#)) or an in-band (VLAN) management-ip address ([interface vlan](#)). The [permit](#) command determines which of these address types are available for access. Use [show interface mgmt](#) and/or [show interface vlan](#) to find the IP addresses for each interface.

This URL accesses the same documentation through HTTPS:

**https://arx-management-ip:843/arx-api/**

where *arx-management-ip* is a valid management IP, as described above.

You can use this command, [show statistics api](#), to find usage statistics for the API.

**Sample** provA# [show statistics api](#)  
shows all API statistics for the “provA” system. See [Figure 34.4](#), below, for sample output.

**Related Commands** [clear statistics api](#)  
[notification rule](#)  
[management access](#)  
[permit](#)

## Disaster Recovery Between ARX Clusters

---

---

---

## activate configs

|                         |                                                                                                                                                                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>          | Use the <code>activate configs</code> command to enable all of the volumes and services in a pre-loaded global-config file. If this site is a backup for another site, this is the final step in performing a disaster-recovery operation. |
| <b>Mode</b>             | priv-exec                                                                                                                                                                                                                                  |
| <b>Security Role(s)</b> | crypto-officer                                                                                                                                                                                                                             |
| <b>Syntax</b>           | <code>activate configs file-name [partial][take-ownership][tentative]</code><br><code>activate replicated-configs file-name ...</code>                                                                                                     |

*file-name* (1-1024 characters) is the name of the global-config file. You can activate a replicated global-config from a remote cluster or a locally-defined global-config file. Use [show replicated-configs](#) for a list of replicated-config files from other clusters, or use [show configs](#) for a list of locally-defined configuration files.

*partial* (optional) activates a subset of the full configuration. This can be any of these keywords, or any combination of them:

**global-server** *fqdn* (1-128 characters) activates a particular global-server configuration, along with all of its component objects (such as its [namespace](#) and all the [shares](#) behind it). This is the fully-qualified domain name (for example, “myserver.myorg.org”) for one global server in the global-config. Use [show replicated-configs file-name](#) to view the global config and see all of its global servers.

**shares** activates all shares.

**volumes** activates all volumes.

**global-servers** activates all global servers.

**policies** activates all rules and share farms.

If you specify any of the above, the command activates only the specified option(s). If you omit all of them, the command enables all global servers, volumes, and shares but does *not* activate any policy rules.

**take-ownership** (optional, but recommended) causes the command to use the **take-ownership** option for every managed-volume share that it enables (see the documentation for [enable \(gbl-ns-vol-shr\)](#)). The filer-replication process typically copies hidden files from the back-end shares at the source site, including files that mark the back-end share as “already imported” by the source site’s ARX. The managed volumes will not import these shares unless the **take-ownership** flag is raised.

**tentative** (optional) creates a report to describe the how the command runs, but does not actually enable any configuration objects. The CLI shows the name of the report after you issue the command. You can use [show reports report-name](#) to review the report and confirm that the command implements the configuration as desired.

`activate replicated-configs file-name ...` is an alternative syntax, with the same options as described above for `activate configs`.

**Default(s)** *partial - shares volumes global-servers*

**Guidelines:** This command is used in a disaster-recovery operation, which requires preparation before the disaster occurs.

**Preparation for Disaster**

**Preparing Back-End Filers**

You begin by using file-replication facilities (such as NetApp's SnapMirror, EMC's SRDF, or RoboCopy) to duplicate the storage from an active site to a backup site. Continuously replicate all of the back-end shares behind the ARX. Also create back-end shares for managed-volume metadata at the backup site, but you do not need to replicate the source site's metadata. The ARX software at the backup site will recreate the metadata there.

Then you begin the process of building a global configuration to be regularly copied from the active site to the backup site. The global configuration includes all storage-service parameters; see [show global-config](#). The peers at the active site run the global configuration during normal service, and the peers at the backup site run it after a disaster.

**Sharing Master Keys and Removing Global-Config from Backup Site**

The ARX peers at both sites must share the same master key in order to share the same global configuration. The *master key* encrypts and decrypts all of the passwords and other Critical Security Parameters (CSPs) in the global-config file. Use the [show master-key](#) command to show an encrypted copy of the master key on the current ARX. The master keys should be synchronized during installation time, as described in the Hardware Installation manuals. If the backup peers have the wrong master key, reset the peers to factory defaults and reset the master key. They should only have their network parameters configured ([show running-config](#)), along with the correct master key. The documentation for [show master-key](#) provides details for this process.

**Connecting Sites with a Full Mesh of RON Tunnels**

At the ARX CLI, use the [ron tunnel](#) command to connect both ARX peers at the active site to both peers at the backup site. That is, each ARX must have two tunnels, one to each peer at the other site.

**Removing All Storage Services from the Backup Cluster**

We recommend removing all namespaces, global servers, and front-end services from the backup cluster before you begin. This prevents any significant configuration conflicts between the active site and the backup site, which could possibly prevent a successful disaster recovery. Ideally, the backup cluster should only have network parameters configured (which you can see with [show running-config](#)), along with administrative accounts ([show group users](#)) and any AD forests that have been discovered in the network ([show active-directory](#)).

If there are any storage services on the backup cluster, we recommend removing them. From the backup cluster's CLI, use [remove service namespace](#) for each namespace in the backup cluster's configuration. The [remove service](#) command removes the namespace configuration along with all associated external-filer definitions, and it also removes ARX metadata from the filers behind the namespace. Then use [no global server](#), [no cifs](#), and/or [no nfs](#) to remove all of the global servers and front-end services at the backup cluster.

---

**Guidelines:  
Preparation for  
Disaster (Cont.)****Building a Shared Global-Config**

Once all ARX peers have the same master key and are connected by RON tunnels, use the [cluster-name](#) command to establish a cluster name for each site. The [cluster-name](#) command also assigns each peer to a cluster. You then expand the active cluster's global configuration so that it can also include the backup cluster's file servers and Virtual-IP addresses:

- Add a new [external-filer](#) object for each of the backup site's filers. After you define them, the active cluster has definitions for all the active site's filers and all the backup site's filers. With both sets of filers defined, you can use the following commands to associate each filer to its role in each cluster:
  - [metadata share ext-filer ... cluster n](#) chooses *ext-filer* to host a metadata share in cluster *n*. You run the command again to choose a different filer for this metadata share at the other cluster.
  - [filer ext-filer ... cluster n](#) chooses a filer to host a storage share in a particular cluster. As above, you run the command twice for each share; once to choose the filer at the active cluster, and another time to choose the filer at the backup cluster.
  - [sam-reference ext-filer ... cluster n](#) chooses *ext-filer* to play the role of a SAM-reference filer in cluster *n*. You run the command again to choose a different filer for SAM at the other cluster.
- Use the [virtual server ... vip ... cluster n](#) command to set the *vip* (Virtual-IP) addresses for use at cluster *n*. This brings you into a submode, with several commands for setting CIFS-service names. The submode, and those service names, are the same for both clusters; if the submode's commands were already set for the active cluster, you can exit the mode without repeating them for the backup cluster.

**Regularly Copying the Global-Config to the Backup Cluster**

This prepares the active cluster's global config so that it is valid at either the active cluster or the backup cluster. Then create a [config-replication](#) rule to regularly copy that global config from the active cluster to the backup cluster.

**Preparing for Snapshot Reconstitution**

If you use any [snapshot rules](#) to back up client data, and if the filer-replication application copies the snapshots to the backup site, we advise that you also prepare for *snapshot reconstitution*. You prepare for snapshot reconstitution by regularly copying snapshot reports off of the active cluster, along with a Perl script in the [configs](#) directory. The guidelines for [snapshot rule](#) describe this preparation process in detail: see [Guidelines: Preparing for Snapshot Reconstitution](#), on page 30-50.

**Guidelines:  
Preparation for  
Disaster (Cont.)**

**Testing the “Load Configs” Operation at the Backup Cluster**

After the global-config is successfully copied to the backup cluster, we recommend an occasional test of the `load configs` command at that cluster. This loads all of the active cluster’s storage services into the database without enabling any shares or volumes. It also loads the Active Directory configuration, which may not be correct for the backup cluster; after the `load` operation, run `active-directory update seed-domain` there to confirm that the AD configuration is correct.

If you are running CIFS services with constrained delegation, you require some additional configuration at the Domain Controller (DC) to support your CIFS clients. The back-end CIFS servers at the backup cluster must be on the “delegate-to” list for each front-end CIFS service; for each `cifs` service, run the `probe delegate-to` command to find any back-end servers that need to be added to the list, and add them at the DC. When you finish, the CIFS service’s “delegate-to” list includes the back-end servers behind *both* clusters. This configuration occurs at the DC, and persists after this load-configs test.

Check the remaining configuration to confirm that it is correct. Then use `remove service` to remove each of the namespaces that you added with the `load configs` command. Finally, use `no global server`, `no cifs`, and/or `no nfs` to remove all of the global servers and front-end services.

**Guidelines: Disaster  
Recovery**

To recover from a disaster, go to the backup cluster and run `load configs` on the global-config file that was copied earlier. This loads the global-config into the database without enabling any shares, volumes, global servers, or policy rules. You can use this command, `activate configs`, to enable any or all of those objects.

Unless you use the `tentative` option, the CLI prompts for confirmation before activating the global-config file. Enter `yes` to proceed.

The best practice is to activate the configuration in stages and verify the success of each stage. Use the following command order, as time allows:

- `activate configs ... shares take-ownership`, then
- `activate configs ... volumes`. Periodically use `show namespace status` to verify that the volumes come online, and that there are no issues blocking your imports. You can use `show namespace` for detailed status.
- `activate configs ... global-servers`. You can use `show cifs-service` and/or `show nfs-service` to confirm that client services are running. Also verify that you can connect to the global server(s) as a client.
- `activate configs ... policy`. (The `policy` keyword is required for the `activate configs` command to enable any rules.) Use `show policy` to confirm that all rules are migrating or otherwise functioning properly.

Alternatively, you can bring up the shares, volumes, and global servers all at once by omitting any specific keywords. After confirming that the services are running properly, you can use `activate configs ... policy` to activate all rules.

If you also prepared for snapshot reconstitution, play back the snapshot reconstitution script as described in [Guidelines: Reconstituting ARX Snapshots](#), on page 30-50.

If the cluster at the failed site is still on the network after the disaster, log into the cluster and use `no enable (gbl-cfg-repl)` to stop copying the global configuration from the now-backup site.

**Guidelines: Report** This command always creates a report to show its actions. The CLI shows the name of the report after you issue this command. You can use `tail report-name follow` to follow the report as the command runs, or `show reports report-name` to view the report after the command has finished.

The configuration file is an ordered list of CLI commands that recreate the global configuration, including all volumes and storage services. The report shows these CLI commands as it runs them. If it reaches a configuration object that already exists in the local database, it shows an INFO message to explain that the object is being ignored. An X appears at the beginning of each ignored line. This includes the `enable` command for each activated configuration object (such as a share or volume); the `load configs` command does not enable any configuration objects.

**Samples** `newptA# activate configs provSvcs.rcfg tentative`

```
Generating activate configuration report:
'act_provSvcs.rcfg_201007060305'.
```

performs a tentative activation of the global-config file, "provSvcs.rcfg."

`newptA# activate configs provSvcs.rcfg shares take-ownership`

This enables the global configuration.

Are you sure? [yes/no] **yes**

```
Generating activate configuration report:
'aact_provSvcs.rcfg_20100709113618'.
```

activates all shares from the above configuration, and takes ownership of them. See [Figure 35.1](#) for a sample report.

**Related Commands** [load configs](#)  
[show global-config](#)

**Figure 35.1** *Sample Report: Activate Configs Report*

```
newptA# show reports act_provSvcs.rcfg_20100709113618.rpt

Generating activate configuration report: 'act_provSvcs.rcfg_20100709113618'.

## cluster-name

**Purpose** A *cluster* is single ARX site, comprised of a redundant pair of ARX systems or a standalone ARX. Use this command to declare a cluster name for any ARX (or redundant-ARX pair) in the current Resilient Overlay Network (RON). This name is required for configuring disaster recovery between two ARX sites.

Use `no cluster-name` to remove a cluster name from the ARX configuration.

**Mode** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `cluster-name cluster-name member peer-a [member peer-b]`  
`no cluster-name cluster-name member peer-a [member peer-b]`

*cluster-name* (1-64 characters) is the name you choose for this cluster.

*peer-a* (1-64 characters) is an ARX that you assign to the above cluster. Each ARX can be assigned to a single cluster only. The ARX must already be on the same RON as the current switch; you can use the `show ron` command for a full list of all switches on the RON.

*peer-b* (1-64 characters) is the redundant peer to the above ARX, if there is one. You can use the `show ron peer-a` command to find if *peer-a* has a redundant peer.

**Default(s)** None.

**Guidelines** This command establishes an ARX site as a *cluster*, capable of failing its global-configuration over to another cluster. You can create two clusters on your RON and set them up in a disaster-recovery configuration, so that one can take over service for the other in the event of a catastrophic failure. The `ron tunnel` command creates a RON tunnel between any two ARX systems on the same WAN; use that command to create a full mesh of RON tunnels between all four peers. Additionally, ensure that all four peers have the same master key, so that they can share their global configurations (see `show master-key` for details).

To set up disaster recovery between two clusters, you designate one cluster as “active” and the other as the “backup” site. Use filer-replication facilities (for example, NetApp’s SnapMirror or EMC’s SRDF) to copy all files and directories from the active site’s back-end filers to their counterparts at the backup site. Once the files and directories are synchronized, add all of the backup cluster’s `external-filers` to the active cluster’s configuration. Use the `filer`, `metadata share`, and `sam-reference` commands to establish how those filers should be used in the backup cluster. Then use the `virtual server` command to establish a new Virtual-IP address and configuration for each global server in the backup cluster. Finally, create a `config-replication` rule to regularly copy this configuration from the active cluster to the backup cluster. This prepares the backup site to take over service from the active site.

If the active site fails, you can then resume your storage services at the backup cluster. To accomplish this, go to the backup cluster and use `load configs` to load the active site’s configuration into the backup cluster’s database, then use `activate configs` to enable all volumes and services at the backup cluster.

**Guidelines: Only One  
Metadata Share Per  
Managed Volume**

A cluster allows the configuration of a single [metadata share](#) per managed volume. If any managed volume has more than one metadata share, this command fails. A single metadata share per volume is required to ensure that the disaster-recovery software can reliably re-create the volume configuration on a backup cluster.

**Guidelines: Removing  
Cluster Configuration**

To remove a remote cluster along with all its associated [filers](#), [metadata shares](#), and [virtual servers](#), use the [remove cluster-config](#) command. You can use the same command on the local cluster to remove the cluster object and all references to it, without actually removing the above objects. The `no cluster-name` command removes only the cluster definition; the CLI rejects this operation if the cluster name is referenced by any of the above objects.

**Sample**

```
provA(gbl)# cluster-name providence member provA provB
provA(gbl)# cluster-name newport member newptA newptB
```

creates two new clusters, “providence” and “newport.” You can now set up one as a backup site for the other.

**Related Commands**

[config-replication](#)  
[load configs](#)  
[activate configs](#)  
[remove cluster-config](#)

---

# config-replication

**Purpose** Use the `config-replication` command to create a rule for replicating the global configuration to an ARX cluster at another site. A *cluster* is a redundant pair of ARX systems. This prepares for a disaster-recovery scenario. If your back-end filers mirror their data between the sites, this rule mirrors the configuration data for managing those filers at each site.

Use the `no` form of the command to delete the rule.

**Modes** gbl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `config-replication name cluster cluster-name`  
`no config-replication name cluster cluster-name`

*name* (1-32 characters) is the name you choose for the rule.

*cluster-name* (1-64 characters) is the name of the source cluster. This cluster must be defined in the database; you can use the `show cluster` command for a complete list of pre-defined clusters.

**Default(s)** None

## **Guidelines: Preparing to Share Configs Between Clusters**

Before you copy the global configuration file from one cluster to another, the cluster members require require matching master keys and a full mesh of RON tunnels.

The *master key* for an ARX encrypts and decrypts the passwords in its global-config file, so it must be the same for all switches that share the global-config. The backup switches should have the same master key as their active counterparts; the master keys should be set accordingly when the backup switches are installed. Refer to the documentation for the `show master-key` command for information on showing the key and possibly changing it on the backup switches.

Every switch in the active cluster must have a `ron tunnel` to every switch in the backup cluster. This provides multiple pathways for copying the global configuration between clusters.

The backup cluster should not have any storage services configured, so that it accepts the latest storage-services configuration from the active cluster without any conflicts. If the backup cluster has any `namespaces`, use `remove service` to cleanly remove each of them. Also use `no global server`, `no cifs`, and/or `no nfs` to remove all of the global servers and front-end services at the backup site.

**Guidelines** The `config-replication` command creates a rule to regularly copy the active cluster's global configuration and send it to the backup cluster. The command puts you into `gbl-cfg-repl` mode, where you have various configuration commands for configuring the config-replication rule. Use the `target-cluster` command to choose the ARX cluster to receive this configuration. Then use the `user (gbl-cfg-repl)` command to enter your administrative credentials at the remote cluster; this gives you permission to write the configuration file there. The `target-file` command provides a name for the file copy. Use the `schedule (gbl-cfg-repl)` command to choose a regular schedule for duplicating the configuration file. We recommend using the `report (gbl-cfg-repl)` command to create a report about each config-replication event. You can also use the `description (gbl-cfg-repl)` command to describe this rule in the output of `show policy`. Finally, use the `enable (gbl-cfg-repl)` command to start the rule.

**Guidelines: Schedule** To create a schedule to be applied to the config-replication rule, use the `gbl schedule` command at the source cluster.

The rule fires as dictated by its schedule: if the schedule has a start time that is earlier than now, the first config replication begins as soon as you enable the rule.

**Guidelines: Reports** As mentioned above, we recommend that you use the config-replication `report` feature to keep a detailed log of all config-replication events. The reports appear on the source cluster: the `show reports` command shows all reports on the switch, including config-replication reports. You can use the standard file-management commands with these reports: `delete`, `rename`, `show reports file-name`, `tail`, and/or `grep`.

**Guidelines: Preparing for Disaster Recovery** The global-config file replicated by this rule must support both clusters before you can use it to recover from a disaster. Expand the active cluster's global configuration so that it can also include the backup cluster's file servers and Virtual-IP addresses:

- Add a new `external-filer` object for each filer at the backup site. With both sets of filers defined on the active cluster, you can use the following commands to associate each filer to its role in each cluster:
  - `metadata share ext-filer ... cluster n` chooses `ext-filer` to host a metadata share in cluster `n`. You run the command again to choose a different filer for this metadata share at the other cluster.
  - `filer ext-filer ... cluster n` chooses a filer to host a storage share in a particular cluster. As above, you run the command twice for each share; once to choose the filer at the active cluster, and another time to choose the filer at the backup cluster.
  - `sam-reference ext-filer ... cluster n` chooses `ext-filer` to play the role of a SAM-reference filer in cluster `n`. You run the command again to choose a different filer for SAM at the other cluster.
- Use the `virtual server ... vip ... cluster n` command to set the `vip` (Virtual-IP) addresses for use at cluster `n`. This brings you into a submode, with several commands for setting CIFS-service names. The submode, and those service names, are the same for both clusters.

This prepares the active cluster's global config so that it is valid at either the active cluster or the backup cluster.

**Sample** `provA(gbl)# config-replication prov2newport cluster providence`

instantiates a new config-replication rule, "prov2newport."

[description \(gbl-cfg-repl\)](#)  
[enable \(gbl-cfg-repl\)](#)  
[schedule](#)  
[show reports](#)

## description (gbl-cfg-repl)

**Purpose** Use the optional `description` command to set a descriptive string for the current config-replication rule. This appears in show commands.

Use the `no` form of the command to delete the description.

**Mode** gbl-cfg-repl

**Security Role(s)** storage-engineer or crypto-officer

**Syntax** `description text`  
`no description`

*text* (1-48 characters) is your description. Surround the text with quotation marks (“”) if it contains any spaces.

**Default(s)** `no description`

**Guidelines** The description appears in the output for [show config-replication](#).

**Sample** `provA(gbl-cfg-repl[prov2newport])# description "send service config to Newport site"`  
specifies a description for the current config-replication rule.

**Related Commands** [config-replication](#)  
[show config-replication](#)

| <b>Default(s)</b>       | <code>no enable</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Guidelines</b>       | <p>You must enable the config-replication rule for the policy engine to use it. Once enabled, the config-replication rule follows its assigned schedule (set with the <a href="#">schedule (gbl-cfg-repl)</a> command) and copies its global-config file to the target ARX cluster (<a href="#">target-cluster</a>).</p> <p>The <code>no</code> form of the command is useful in a formerly-active cluster that is still on the network. Use the <code>no enable</code> command to stop the cluster at the failed site from copying its configuration to the newly-active site.</p> |
| <b>Samples</b>          | <pre>provA(gbl-cfg-repl[prov2newport])# enable     enables the "prov2newport" rule.</pre> <pre>bstnA(gbl-cfg-repl[dr-test])# no enable     disables the "dr-test" rule.</pre>                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Related Commands</b> | <a href="#">config-replication</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## load configs

**Purpose** The *global-config* parameters are shared among both ARXes in a redundant pair. (The traditional *running-config* applies only to the local switch.) You can copy the *global-config* from one redundant pair to another, so that the second redundant pair (called an ARX *cluster*) can act as a backup for the first. Use this command, **load configs**, to load a *global-config* into the local database without enabling any configuration objects.

This is the first step in disaster recovery; this cluster can use the loaded configuration to take over services from the failed cluster.

**Mode** priv-exec

**Security Role(s)** crypto-officer

**Syntax** **load configs** *file-name* [*global-server fqdn*] [*tentative*]  
**load replicated-configs** *file-name* ...

*file-name* (1-1024 characters) is the name of the *global-config* file. You can load a replicated *global-config* from a remote cluster or a locally-defined *global-config* file. Use [show replicated-configs](#) for a list of replicated-*config* files from other clusters, or use [show configs](#) for a list of locally-defined configuration files.

*fqdn* (optional, 1-128 characters) selects a particular *global-server* configuration, along with all of its component objects (such as a [namespace](#) and all the [external-filers](#) behind it). This is the fully-qualified domain name (for example, “myserver.myorg.org”) for one *global server* in the *global-config*. Use [show replicated-configs file-name](#) to view the *global config* and see all of its *global servers*.

**tentative** (optional) creates a report to describe the how the command runs, but does not actually commit any configuration changes to the database. The CLI shows the name of the report after you issue the command. You can use [show reports report-name](#) to review the report and confirm that the command implements the configuration as desired.

**load replicated-configs file-name ...** is an alternative syntax, with the same options as described above for **load configs**.

**Default(s)** None

**Guidelines** After proper preparations have been made for disaster recovery (see the documentation for the [config-replication](#) command), you can use this command as a first step toward recovering from a disaster at a remote site. After you run this command to load the configuration, use [activate configs](#) to enable it and start client services at the current cluster.

---

**Guidelines: Reports** This command always creates a report to show its actions. The CLI shows the name of the report after you issue this command. You can use `tail report-name follow` to follow the report as the command runs, or `show reports report-name` to view the report after the command has finished.

The configuration file is an ordered list of CLI commands that recreate the global configuration, including all volumes and storage services. The report shows these CLI commands as it runs them. For every configuration object that the `load` operation ignores, an INFO message appears before the object to explain why it was skipped. An X appears at the beginning of each ignored line.

**Guidelines: Rules for the Load Operation** The `load` operation skips configuration objects that meet any of the following criteria:

- A configuration object of the same name already exists on this ARX. The `load` operation does not overwrite existing configuration objects.
- The exception to the above rule is the `namespace` configuration. The `load` operation merges namespaces by creating any volumes, shares, and rules that are not already present in the local configuration.

**Guidelines: Loading Configurations from Higher-Rev Systems** If you use a configuration from a newer release of ARX software, edit the script before you load it. Command syntax may have changed as well as the best practices for command order. Consult this manual (and other documentation from the current release) for the correct syntax, and change the configuration file's commands as needed.

The `load` operation prompts for confirmation if it finds that the configuration is for a newer release. After you edit the configuration, enter `yes` to proceed.

**Guidelines: Recommendations** We recommend running this command on a cluster without any storage services in its global configuration. If any object in the `global-config` file has the same name as an object that already exists, the `load` operation typically does *not* change the object that already exists. Therefore, if you load a configuration onto a backup cluster and leave it there, change the configuration on the active cluster, and copy the changed configuration to the backup cluster to load it again, many (possibly all) of the configuration changes are ignored at the backup cluster.

If you run a test `load` before any disaster, we recommend using `remove service` for each loaded service after you finish. Also use `no global server`, `no cifs`, and/or `no nfs` to remove all of the global servers and front-end services.

Contact F5 Support for advice if you wish to retain different `global-config` parameters at the backup site.

**Samples** newptA# load configs provSvcs.rcfg tentative

```
Generating load configuration report:
'load_provSvcs.rcfg_201007010258'.
```

performs a tentative load of the global-config file, “provSvcs.rcfg.”

newptA# load config provSvcs.rcfg

```
Generating load configuration report:
'load_provSvcs.rcfg_201007091136'.
```

loads the same configuration file into the local database. A sample report appears in [Figure 35.2](#).

# remove cluster-config

**Purpose** Use the `remove cluster-config` command to delete a `cluster-name` from the database along with any references to that cluster name. If you use this with the remote cluster name, this removes all `filers`, `metadata shares`, and/or `virtual servers` associated with that cluster. If you use this with the current cluster name, this only removes the cluster name from those configuration objects, leaving them otherwise intact.

**Modes** `priv-exec`

**Security Role(s)** `storage-engineer` or `crypto-officer`

**Syntax** `remove cluster-config cluster-name`

*cluster-name* (1-64 characters) identifies the cluster. You can use the `show cluster` command for a complete list of configured clusters.

**Default(s)** None.

**Guidelines** The CLI prompts for confirmation before removing or changing any configuration objects; enter `yes` to proceed.

For a remote cluster, this removes the following objects from the system:

- any `filer`,
- any `metadata share`, or
- any `virtual server` that resides in the cluster.

For the local cluster, this only removes the cluster name from the above objects. They remain in the configuration, but without the cluster name as part of their definitions.

If any of the above object types refer to a cluster name, you cannot use `no cluster-name` to remove the cluster name. This command exists as a convenience; it is a single command for removing the cluster name and all of its dependent configuration.

To change the name of the local cluster, you can use this command to remove the current name and then use the `cluster-name` command to add the new cluster name to all of the above objects at once.

**Sample** `bstnA# remove cluster-config portland`

This removes all configuration for this cluster.

Are you sure? [yes/no] `yes`

removes all configuration objects associated with the “portland” cluster.

**Related Commands** `cluster-name`

## report (gbl-cfg-repl)

- Purpose** Use this command to enable progress reports for the current config-replication rule.  
Use `no report` to prevent progress reports.
- Mode** `gbl-cfg-repl`
- Security Role(s)** `storage-engineer` or `crypto-officer`
- Syntax** `report file-prefix [verbose]`  
`no report`
- file-prefix* (1-1024 characters) sets a prefix for all config-replication reports from this rule. Each report has a unique name in the following format:
- prefixYearMonthDayHourMinute.rpt*
- For example, `gblRepl2newport201003031200.rpt` could be the name for one report with the “`gblRepl2newport`” prefix.
- verbose** (optional) enables verbose data in the reports.
- Default(s)** `no report`
- Guidelines** Every time the config-replication rule fires and duplicates the global-config, the rule can generate a report to show the details of the copy session. The reporting feature is disabled by default; we recommend that you enable reporting for all config-replication rules, to keep a log of all these copy sessions.
- Use [show reports](#) for a list of reports, or `show reports file-name` to show the contents of one report.
- Samples**
- ```
provA(gbl-cfg-repl[prov2newport])# report gblRepl2newport
    enables reports for the config-replication rule, “prov2newport.” For a sample
    report, see Figure 35.3.
```
- ```
bstnA(gbl-cfg-repl[dr-test])# report drTest verbose
 enables verbose reports for the config-replication rule, “dr-test.”
```
- ```
newptA(gbl-cfg-repl[newpt2prov])# no report
    disables reports for the “newpt2prov” rule.
```
- Related Commands** [config-replication](#)

```

schedule (gbl-cfg-repl)

Purpose	Use this <code>schedule</code> command to assign a schedule to the current config-replication rule. Use <code>no schedule</code> to remove the rule's schedule.
Mode	<code>gbl-cfg-repl</code>
Security Role(s)	<code>storage-engineer</code> or <code>crypto-officer</code>
Syntax	<code>schedule name</code> <code>no schedule</code> <i>name</i> (1-64 characters) identifies the schedule. Use show schedule for a list of configured schedules.
Default(s)	None.
Guidelines	A config-replication rule copies the global-configuration from the current ARX to another ARX at a backup site. This copy operation occurs on the schedule you choose with this command. To create a schedule, use the <code>gbl-mode schedule</code> command. You cannot use a schedule with a fixed duration ; a config-replication rule must always run to completion in order to succeed.
Sample	<pre>provA(gbl-cfg-repl[prov2newport])# schedule oncePerDay</pre> assigns the "oncePerDay" schedule to the config-replication rule, "prov2newport."
Related Commands	config-replication schedule show schedule

show cluster

Purpose Use the `show cluster` command to get a list of all ARX *clusters*, or redundant pairs, known to the current ARX. You can set up ARX clusters so that one cluster can act as a backup for another.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show cluster [cluster-name]`

cluster-name (optional, 1-64 characters) shows only the chosen cluster.

Guidelines The summary output shows a table of clusters, one row per cluster. Each row has the following columns:

Cluster Name identifies the cluster. You set this when you use the `cluster-name` command to create the cluster.

Member is the `hostname` of one ARX in the cluster (typically a redundant pair).

Member in the next column is for the above switch's redundant peer, if there is one.

Samples `provA# show cluster`
shows all clusters. See [Figure 35.4](#) for sample output.

`provA# show cluster newport`
shows one cluster. See [Figure 35.5](#) for sample output.

Related Commands [cluster-name](#)

Figure 35.4 Sample Output: show cluster

```
provA# show cluster

Cluster Name      Member              Member
-----
providence        provA
newport           newptA
```

Figure 35.5 Sample Output: show cluster newport

```
provA# show cluster newport

Cluster Name      Member              Member
-----
newport           newptA
```

show config-replication

Purpose Use the `show config-replication` command to see the current status of one or more config-replication rules. A config-replication rule copies the global config (see [show global-config](#)) from the current site to an ARX at a disaster-recovery site.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show config-replication [rule-name]`

rule-name (optional, 1-32 characters) provides configuration details for a particular config-replication rule.

Guidelines: Summary Output The summary output shows a table of config-replication rules, one row per rule. Each row has the following columns:

Name identifies the rule. You set this when you use the [config-replication](#) command to create the rule.

Cluster is the name of the target ARX cluster (or redundant pair) where the rule sends its global configuration file. You can set this with the [target-cluster](#) command.

Filename is the name of the configuration file that the rule creates at the remote cluster. You can change this with the [target-file](#) command.

Schedule is the name of the schedule for the config-replication rule. Use the [schedule \(gbl-cfg-repl\)](#) command to assign a schedule to the rule.

Admin State is “Enabled” or “Disabled,” depending on the setting of the [enable \(gbl-cfg-repl\)](#) command.

Guidelines: Detailed Output Detailed output appears when you specify a config-replication rule in the command. The detailed output contains these fields:

Name identifies the rule, as described above.

Description describes the rule, as specified with the [description \(gbl-cfg-repl\)](#) command.

Cluster is the name of target cluster, as described for the summary output above.

Target Filename is the name of the configuration file that the rule creates. This is the same as the **Filename** in the summary output.

Report Prefix shows the prefix used in all of the rule’s reports. The reports appear on the source cluster. You can use the [report \(gbl-cfg-repl\)](#) command to change this prefix.

Username is the administrative user name used for authentication at the remote cluster. These credentials confirm that the rule is authorized to write the configuration file. This is a valid administrative [user](#) at the ARX cluster that receives the copy.

Admin State is “Enabled” or “Disabled,” as described above for the summary output.

Guidelines: Detailed Output (Cont.)

Status shows the results of the last attempt to copy the global-config:

- “Copy Successful” indicates a success.
- “Not Copied Yet” means that the rule’s [schedule \(gbl-cfg-repl\)](#) has not started yet.
- “The config-replication target-cluster is not defined for *rule*.” shows that the copy failed because the [config-replication](#) rule has no target. You can use the [target-cluster](#) command to define a target cluster for the copy operation.
- “The config-replication user is not defined for *rule*.” shows that the copy failed because the [config-replication](#) rule has no user defined. The rule needs an administrative user name that is valid at the target cluster, so that it has permission to copy a file onto the remote ARX. You can use the [user \(gbl-cfg-repl\)](#) command to identify an administrative account for the copy operation.
- “File *file-name* does not exist.” means that an internal process failed to open *file-name*, a temporary version of the global-config file. This indicates an internal error; contact F5 Support if you see this.
- Any other error indicates a low-level error with the SCP process. Contact F5 Support if you see any such error in this field.

[Schedule](#) is the schedule’s configured name, chosen with the [schedule \(gbl-cfg-repl\)](#) command. The fields in this table show the configuration of the schedule.

- **Start Time** can be reset by the `gbl-schedule start` command. This is the date and time of day used for all time-based calculations: for example, if a schedule runs every Saturday, this determines the time of day on Saturdays when the schedule fires.
- **Interval** is set by the `gbl-schedule every` command. This is the time between scheduled runs.
- **Status** is “Paused” (the schedule is between run times), “Running,” or “Waiting for start time” (the schedule has never been invoked).
- **Previous** is a sub-table showing the **Run time** (when the run started) and **End time** of the most-recent run.
- **Current** appears if the rule is currently running. This has the same fields as the **Previous** table, **Run time** and **End time**.
- **Next** shows when the schedule’s next run will begin. It also has the **Run time** and **End time** fields.

Samples `provA# show config-replication`

shows the status of all config-replication rules. See [Figure 35.6](#) for sample output.

`provA# show config-replication prov2newport`

shows the detailed status for a particular rule. See [Figure 35.7](#) for sample output.

Related Commands [config-replication](#)

  Run Time: Mon Sep 20 03:36:00 2010 (Schedule Start)
  End Time: N/A

Next:
  Run Time: Tue Sep 21 03:36:00 2010
  End Time: N/A
```

target-cluster

Purpose Use the `target-cluster` command to choose a remote ARX cluster as a target for copies of the local cluster's configuration. The current config-replication rule copies the global-configuration from the local cluster on a schedule. This prepares the remote cluster as a backup for the local cluster in the event of a disaster at the local site.

Mode gbl-cfg-repl

Security Role(s) storage-engineer or crypto-officer

Syntax `target-cluster cluster-name`

cluster-name (1-64 characters) is the target cluster for the copy of the global-config file. This cluster must be defined on the current ARX; use the [show cluster](#) command for a list of defined clusters, or the [cluster-name](#) command to define one.

Default(s) None.

Guidelines This command sets a cluster target for the current config-replication rule. A *cluster* is a redundant pair of ARX peers (see [redundancy](#)), or possibly a standalone ARX.

Sample `provA(gbl-cfg-repl[prov2newport])# target-cluster newport`
uses the "newport" cluster as the target for the "prov2newport" rule.

Related Commands [config-replication](#)
[cluster-name](#)
[show cluster](#)

target-file

Purpose The current config-replication rule copies the global-configuration from the local cluster to a remote cluster on a schedule. Use the **target-file** command to choose the name of the remote copy. The copy operation prepares the remote cluster as a backup for the local cluster in the event of a disaster.

Mode gbl-cfg-repl

Security Role(s) storage-engineer or crypto-officer

Syntax **target-file** *file-name*

file-name (1-255 characters) is the file name for the destination file.

Default(s) None.

Guidelines This command sets a file-name target for the current [config-replication](#) rule. A *cluster* is a redundant pair of ARX peers (see [redundancy](#)), or possibly a standalone ARX. A config-replication rule copies the local cluster's global configuration (see [show global-config](#)) to a remote cluster. This prepares the remote cluster as a backup for the local cluster, in case of a disaster at the local site.

Sample `provA(gbl-cfg-repl[prov2newport])# target-file provSvcs.rcfg`
uses the name, "provSvcs.rcfg," as the target file name for the "prov2newport" rule.

Related Commands [config-replication](#)

user (gbl-cfg-repl)

Purpose When you use a [config-replication](#) rule to copy the global configuration to a remote ARX cluster, you require an administrative username and password for the remote peer. Use the `user` command to set this username and password.

Use the `no` form of this command to remove the administrative credentials, effectively disabling the config-replication rule.

Mode gbl-cfg-repl

Security Role(s) storage-engineer or crypto-officer

Syntax `user name`
`no user`

name (1-32 characters) is a valid administrative [user](#) at a remote ARX.

Default(s) None.

Guidelines The CLI prompts twice for a password. See the sample below.

Sample

```
provA(gbl-cfg-repl[prov2newport])# user admin
Password: s3cr3tpasswd
Validate Password: s3cr3tpasswd
provA(gbl-cfg-repl[prov2newport])# ...
    provides a username and password, admin and s3cr3tpasswd, for sending
    global-config copies to a remote ARX.
```

Related Commands [config-replication](#)

36

Software Upgrades

boot system

Purpose To upgrade (or otherwise change) switch software, you must arm the switch with a new release file and then restart all of the switch modules. Use the **boot system** command to arm the ARX with a release file.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax **boot system** *release-file*

release-file (1-1024 characters) identifies the release file. Use the **show directories releases** command to see all available release files. Use **copy** to copy a release file to the switch.

Default(s) None

Guidelines To upgrade switch software, you must

- obtain a new release file from <https://downloads.f5.com/esd/productlines.jsp>,
- use **copy** to copy the new release file to the switch,
- use **license activate** or **license activate file** if you have never done so, or if you renewed your license to be eligible for this release,
- use **boot system** to arm the switch with the new release file, and
- use **reload** to restart all modules and put the new release file into service.

Use **show boot** to verify that the switch is armed with the new release file.

To revert to an older release after an upgrade, you can downgrade the switch to the old software. You should only do this under the guidance of F5 Support. Downgrading deletes all configuration parameters, both the running-config and the global-config; save both configuration files off of the box before you use this command to downgrade (use **copy running-config** and **copy global-config**). Then edit the config files so that they only use CLI commands from the downgrade release. Use **boot system** to select the old release, then use **reload** to install it. When you enter the **boot system** command, a CLI prompt asks for confirmation before deleting the configuration. Enter **yes** to continue. After the **reload**, copy the edited config files onto the system, **run** the running-config, use **license activate** to enable the license, and then **run** the global-config.

Each release file may contain module firmware bundled with the software. The release installation (after reboot) puts all such firmware into flash memory on each module, ready to be installed. Use the **show firmware upgrade** command to enumerate any modules that have newer versions of firmware waiting for them. To install the new firmware onto the module(s), use **firmware upgrade**.

In a redundant pair of switches, you upgrade the backup peer before you upgrade the active peer. This command only runs on the backup peer in any redundant pair.

**Guidelines: Licensing
for New Releases**

The following error indicates that you are not licensed for the new software release:

The current license is not eligible to upgrade to x.y.z. The service contract is not active as of *service-check-date*. Please re-activate the license to get current service contract information before performing the upgrade.

Contact F5 Support to renew or extend your service contract, then run the [license activate](#) or [license activate file](#) command to reactivate your license.

**Guidelines: ARX-1500
and ARX-2500
Redundancy**

The ARX-1500 and ARX-2500 store their metalog data on their internal disks, along with logs, software-release files, and other management data. Managed volumes write their metalog data as clients change the volume state; the metalog is used to restore the volume configuration in the event of a failure. The metalog is also copied to the redundant peer, if there is one (see [redundancy](#)). The speed of many volume operations depends on fast metalog writes.

Some other system operations create a large number of writes to the internal disk, potentially slowing metalog writes. This can slow volume performance, even if it occurs on the backup peer. The process of upgrading the software release is extremely disk intensive, and may cause a noticeable performance degradation. During an upgrade, you use

- the `copy` command ([copy ftp](#), [copy {nfs|cifs}](#), [copy scp](#), or [copy tftp](#)) to copy a full release file to the disk, and
- this command ([boot system](#)) to unpack the release file on the disk.

You should perform such disk-intensive operations during off-peak hours on the ARX-1500 and ARX-2500. This is true whether you run the operations on the active peer or the backup.

Samples

```
bstnA# copy nfs wmed /rcrds/.admin/ 12345.rel releases new.rel
bstnA# boot system new.rel
```

```
% INFO: The boot system command may take up to 5 minutes to complete.
        arms the switch with a release file, "new.rel," to be loaded onto all modules at next
        reboot.
```

```
bstnA# boot system previous.rel
```

```
WARNING: Arming this release will cause your configuration to be reset
to factory default because it is a lower version than the running
release.
```

```
Proceed? [yes/no] yes
```

```
% INFO: The boot system command may take up to 5 minutes to complete.
        reverts the switch to an older release. This removes all configuration parameters
        from the system.
```

[show boot](#)

firmware upgrade

Purpose	A software installation may include firmware upgrades for the chassis modules, but does not install the new firmware. Use the <code>firmware upgrade</code> command to install firmware from a new software release.
Mode	<code>priv-exec</code>
Security Role(s)	<code>network-technician</code> , <code>network-engineer</code> , <code>storage-engineer</code> , or <code>crypto-officer</code>
Syntax	<code>firmware upgrade {slot-id all}</code>

slot-id (1-2) loads the firmware into the given slot only. The firmware is installed and activated the next time the switch reboots. This option is only valid on an ARX-4000.

all loads and installs the latest firmware on all modules in the chassis. This causes the ARX to reboot.

Default(s) None.

Platforms ARX-500, ARX-1500, ARX-2000, ARX-2500, and ARX-4000

Guidelines The CLI prompts for confirmation before upgrading any firmware; enter **yes** to proceed.

Use this command only as directed by F5 personnel.

Firmware is low-level software, such as BIOS, the RAID controller, software for the FPGAs, and the software components that manage the system's boot process. Each module type has a different set of FPGAs; these include the System-Status Bus (SSB) FPGA, the Non-Volatile RAM (NVR) FPGA, the MetaLog (MTL) FPGA, the franklog FPGA, and the macau FPGA. Module startup is managed by a set of three additional firmware components: the *bootstrap* software starts the hardware, then the *diagnostics* run to verify the hardware functions, and finally the *boot-loader* loads and starts all of the system software. The `show firmware upgrade` and `show chassis moduleinfo` commands show the versions for all of these components and FPGAs.

You can use the `show firmware upgrade` command to see if there is a difference between running and waiting versions of firmware, or to see the status of a firmware upgrade that you invoked with this command.

The `firmware upgrade all` command reboots the ARX. If the ARX is in a redundant pair, you can only use this syntax on the backup ARX. Certain RAID-maintenance processes also block the `firmware upgrade all` command: a `raid rebuild` (which you can stop with `raid offline`) or a `raid verify` (which you can stop with `no raid verify`).

A full firmware upgrade can take several minutes. If new BIOS is included, the upgrade can take 30 minutes or more.

Use the `boot system` and `reload` commands to install a full software release package, including (possibly) new firmware releases.

Sample bstnA# `firmware upgrade all`

Confirmation of this command commences a firmware upgrade on the entire chassis. During the upgrade process, the chassis reboots automatically to complete the upgrade process. If this includes a bios upgrade, this could take at least 30 minutes.

Proceed? [yes/no] `yes`
 upgrades the firmware in all slots.

Related Commands [show firmware upgrade](#)
 [show chassis moduleinfo](#)
 [boot system](#)

show boot

Purpose	The ARX can be <i>armed</i> with a waiting release file, meaning that the waiting release is swapped with the running release the next time the modules are rebooted. Use the <code>show boot</code> command to see both the running release and the armed release.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>show boot</code>
Guidelines	<p>The armed release is labeled “System Release” and the running release is labeled “System Configuration.” The following format appears for each build:</p> <p>Version <i>version</i> (<i>build-date build-time</i>) [<i>user</i>]</p> <p>Use boot system to arm the switch with the new release file. Use reload to restart all modules and put the new release file into service.</p>
Sample	<pre>bstnA(cfg)# show boot System Release Version 5.00.000.12345 (Feb 26 2009 20:38:56) [nbuilds] %X0A System Configuration Version 500000.7</pre>
Related Commands	boot system reload

show chassis software

- Purpose** Use the `show chassis software` command to see the software version(s) running, armed, and otherwise available on the chassis.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show chassis software`
- Guidelines** System Software shows two software-release files:
 Armed is the software-release file to be loaded on the next reboot, if any. Use [boot system](#) to arm the switch with a new release file. Use [reload](#) to restart all modules and put the new release file into service.
 Running is the software-release file that is currently running.
 The next table describes all release files on the switch:
 Version
 Date is the date the release-file was installed on the ARX.
 Size is in bytes.
 Filename
- Related Commands** [boot system](#)
[reload](#)

```

show firmware upgrade

Purpose Module firmware comes bundled with new software releases, but it is not installed on the modules along with the software. Use the `show firmware upgrade` command to determine whether or not the latest software release has new firmware for your modules.

Mode (any)

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `show firmware upgrade [verbose]`

verbose (optional) expands the output with detailed version numbers for each firmware package and module.

Valid Platforms ARX-500, ARX-1500, ARX-2000, ARX-2500, and ARX-4000

Guidelines You can use the `firmware upgrade` command to manually install the firmware after the software is installed. Use the `show firmware upgrade` command to view the running versions of firmware along with the versions that may be waiting.

The summary version shows a table with two columns: Slot and Status Summary. The Status Summary for each slot compares the running firmware with the firmware that is available from the installed software release: “Up to date,” “Pending,” “Upgrade available,” and “Upgrade in progress” are possible values.

The verbose output has a larger table with the following columns:

Slot is the slot number for the module in question.

Firmware shows the type of firmware. They appear in the following order:

- The “BIOS Firmware” runs on the processor cores. This only appears for the platforms that support BIOS-firmware upgrades.
- The “Raid Ctrl,” “Intel(R) RAID Controller ...,” or “MegaRAID SCSI ...” is the RAID-controller firmware for the internal hard drives.
- The remaining rows contain slot-specific firmware. “Bootstrap,” “Diag,” and “BootLoader” are the three components that manage the module’s boot process. The NSM versions of these are “NSM Boot,” “NSM Diag,” “NSM Exp ROM,” and “NSM BootLdr.” “SSB,” “NVR,” “MTL,” “LBA,” “Firetruck,” “Hunchback,” “Franklog,” and “Macau” are examples of FPGAs.

Running is the running version of each firmware package.

Current is the version that is bundled with the running-software release.

Status is the same as shown in the summary output.

Samples bstnA(cfg)# show firmware upgrade
Show Firmware Update

Slot Status Summary

1 Up to date
2 Up to date

shows the high-level status for an ARX-4000 chassis.

bstnA(cfg)# show firmware upgrade verbose

shows detailed firmware status for the same ARX. See [Figure 36.2](#) for sample output.

prtlnA# show firmware upgrade verbose

shows the same level of detail for an ARX-2000. See [Figure 36.3](#) for sample output.

37

Namespace Check (nsck) and Sync

cancel migrate-metadata

Purpose	You can use the nsck ... migrate-metadata command to move a managed volume's metadata from one back-end share to another. Use this command to cancel a metadata migration that is currently in progress.
Modes	priv-exec
Security Role(s)	network-technician, network-engineer, storage-engineer, crypto-officer, or backup-operator
Syntax	cancel migrate-metadata <i>namespace</i> volume <i>volume</i> <i>namespace</i> (1-30 characters) and <i>volume</i> (1-1024 characters) specify the volume whose metadata is migrating between back-end shares. The nsck utility performs metadata migrations; use the show nsck command for a list of volumes where the nsck utility is running.
Default(s)	None
Guidelines	The CLI prompts for confirmation before canceling the metadata migration; enter yes to continue. This stops the volume's metadata from migrating and returns the volume to service. The managed volume uses its original metadata share after the cancellation. If the migration is complete and the volume is in the process of restarting with the new metadata share, this command fails. Use the nsck ... migrate-metadata command to start a metadata migration.
Sample	bstnA# cancel migrate-metadata insur volume /claims Are you sure you want to cancel this migration? [yes/no] yes Metadata migration cancelled successfully. bstnA# cancels the migration in progress for the "insur~/claims" volume.
Related Commands	nsck ... migrate-metadata show nsck

cancel migrate-volume

Purpose You can use the [nsck ... migrate-volume](#) command to move an ARX volume from one [volume-group](#) to another. Use this command to cancel a volume migration that is currently in progress.

Modes priv-exec

Security Role(s) storage-engineer or crypto-officer

Syntax `cancel migrate-volume namespace volume volume`

namespace (1-30 characters) and
volume (1-1024 characters) specify the volume that is migrating between volume groups.

Default(s) None

Guidelines The CLI prompts for confirmation before canceling the volume migration; enter **yes** to continue. This stops the volume from migrating and returns the volume to service in its original volume group. The cancellation may take a long time in a large volume.

If the migration has already progressed to the point where the volume is restarting in its new volume group, this command fails. If necessary, you can re-run the [nsck ... migrate-volume](#) command to send the volume back to the original group.

You can use [show volume-group](#) to show the current volume group for every volume. Use the [show nsck](#) command to monitor the progress of a volume migration.

Sample

```
bstnA# cancel migrate-volume medarcv volume /rcrds
Are you sure you want to cancel this migration? [yes/no] yes
...
bstnA#
```

 cancels the migration in progress for the “medarcv~/rcrds” volume.

Related Commands [nsck ... migrate-volume](#)
[show volume-group](#)
[show nsck](#)

cancel nsck report

Purpose	To stop an nsck-report job (nsck ... report metadata-only or nsck ... report inconsistencies), use the <code>cancel nsck report</code> command.
Mode	priv-exec
Security Role(s)	network-technician, network-engineer, storage-engineer, or crypto-officer
Syntax	cancel nsck report <i>nsck-id</i> <i>nsck-id</i> (1-2,147,483,647) identifies one nsck-report job that is currently running. The job ID appears if you run show nsck without any options.
Guidelines	This command prompts for confirmation before stopping the report; enter yes to continue. This command has no effect on nsck jobs that do more than produce a report, such as those invoked by nsck ... destage or nsck ... rebuild .
Samples	bstnA# cancel nsck report 22 Cancel the nsck metadata-only report operation 'metadata_only.21.rpt'? [yes/no] yes bstnA# cancels a metadata-only report.
Related Commands	show nsck nsck ... report inconsistencies nsck ... report metadata-only

cancel sync

Purpose If a file or directory changes on a back-end filer without the managed volume's awareness, the volume metadata is *inconsistent* for that file. A *sync* operation discovers which files or directories are inconsistent and re-synchronizes them with the metadata; the **cancel sync** command stops a sync operation.

Modes priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax **cancel sync** {files | directories} *namespace* *volume* *volume* *path* *dir-path*

files | **directories** chooses the type of sync operation to cancel.

namespace (1-30 characters) is the namespace where the sync is occurring. Use the [show sync](#) command for a list of namespaces that are being synchronized.

volume (1-1024 characters) specifies the managed volume where the sync is occurring.

dir-path (1-1024 characters) specifies the directory that is being synchronized within the volume, if any. This path is relative to the **volume** root, above. Use forward slashes (/) for NFS or CIFS paths.

Default(s) None

Guidelines The CLI prompts for confirmation before canceling the sync operation; enter **yes** to continue.

Use the [sync files](#) command to find files with metadata inconsistencies and repair them, or the [sync directories](#) command to find new directories on the filer that are not recorded in the metadata. Sync operations happen in the background while you continue to use the CLI; you can use the [wait-for sync](#) command to block the CLI until the sync is complete. To show all sync operations, use [show sync](#).

Sample bstnA# **cancel sync files wwmed volume /acct path /jsmith**
Cancel specified sync operations? [yes/no] **yes**
bstnA#

cancels the sync-files operation in progress for the /jsmith directory in the "wwmed~/acct" volume.

Related Commands [sync files](#)
[sync directories](#)
[wait-for sync](#)
[show sync](#)

clear nsck

Purpose Use this command to clear a pending or complete nsck job, or to clear all such nsck jobs.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear nsck [nsck-id]`

nsck-id (optional, 1-2,147,483,647) identifies the nsck job to clear. The job ID appears in the report name for the nsck job. If you do not include an ID, the command clears all nsck jobs.

Default(s) None

Guidelines The CLI prompts for confirmation before executing the command. Use the [show nsck](#) command to view all nsck jobs that have run on this switch. After you issue this command, `show nsck` does not show any pending or complete nsck jobs.

This command does not delete any nsck report files, which you can view with the [show reports](#) command.

Sample(s) `bstnA# clear nsck 4`
`Clear NSCK ID 4? [yes/no] yes`
clears the nsck job for nsck ID #4.

Related Commands [show nsck](#)
[show reports](#)

clear sync

Purpose The ARX holds its sync-operation records indefinitely, so that you can see the results of every sync operation through [show sync](#). Use the `clear sync` command to remove sync operations from this running history.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear sync {files | directories}`
`clear sync {files | directories} namespace`
`clear sync {files | directories} namespace volume vol-path`
`clear sync {files | directories} namespace volume vol-path path path`

files | directories is a required choice. This selects the type of sync-operation records to clear.

The *namespace*, *vol-path*, and *path* arguments mimic the ones used in the [sync files](#) and [sync directories](#) commands. These identify one or more sync operations; if you omit all of them, the command clears all sync-files or sync-directories operations from the switch.

namespace (1-30 characters) specifies a namespace where one or more sync operations have occurred.

vol-path (optional, 1-1024 characters) specifies a volume. Use forward slashes (/) for all volumes, including CIFS.

path (optional, 1-1024 characters) identifies a particular path that has been synchronized. As with volumes, use forward slashes in all paths.

Default(s) None

Guidelines The CLI prompts for confirmation before deleting any sync records. Enter **yes** to continue.

Use [show sync](#) to show all recorded sync operations. This command clears them; after you run it, the `show sync` command no longer displays the cleared operation(s).

The [sync files](#) and [sync directories](#) commands each start a sync operation (which runs in the background while you continue to use the CLI), [cancel sync](#) cancels a running sync, and [wait-for sync](#) blocks the CLI until a running sync completes.

Samples

```
bstnA# clear sync files wwmed
Clear sync records? [yes/no] yes
bstnA#
clears all sync-files operations from the "wwmed" namespace.
```

```
bstnA# clear sync directories
Clear sync records? [yes/no] yes
bstnA#
clears all sync-directories operations on the switch. The show sync directories command displays nothing after you do this.
```

Related Commands [sync files](#)
[sync directories](#)
[show sync](#)
[cancel sync](#)
[wait-for sync](#)

nsc ... destage

Purpose	Use the <code>nsc destage</code> command to release all back-end shares from a managed volume. Once destaged, you can access the volume's filer(s) directly without risking any metadata inconsistencies.
Mode	priv-exec
Security Role(s)	storage-engineer or crypto-officer
Syntax	<code>nsc name destage [force]</code> <code>nsc name destage volume-group id [force]</code> <code>nsc name destage volume volname [force]</code>

name (1-30 characters) is the name of the namespace where the destage occurs. Use the [show namespace](#) command to see a list of configured namespaces.

destage directs the `nsc` utility to destage the namespace metadata and prepare it for re-import.

volume-group id (optional) chooses all of the volumes in the given volume group. A *volume group* shares CPU and memory resources, and can fail over from one chassis to another in a redundant configuration. It is also a failure domain for a group of volumes in the same namespace. Use the [show volume-group](#) command to show all volume groups and their volumes. Before a volume is enabled, you can use [volume-group](#) to assign it to a group. This command destages all of the volumes assigned to the group that you choose.

volume volname (optional, 1-256 characters) is the volume to destage (for example, '/var').

force (optional) indicates that you want to force the destage even if another `nsc` job is currently under way. You can force any `nsc` job with this option except [nsc ... migrate-metadata](#) or [nsc ... migrate-volume](#); you must cancel those jobs explicitly (with [cancel migrate-metadata](#) or [cancel migrate-volume](#)) before you can destage the volume.

Default(s) None.

Guidelines This applies to a managed volume only, not to a [direct](#) volume.

The CLI asks for confirmation before releasing any volume's shares; enter **yes** to continue. This stops all client access to any of the destaged volumes.

Once the filer or share(s) have been removed and/or restored to health, you can use the `enable shares` command to re-import all shares into a managed volume (see [enable \(gbl-ns, gbl-ns-vol\)](#)). After the re-import, all NFS clients must unmount and remount any of the volume's front-end NFS exports ([export \(gbl-nfs\)](#)).

◆ **Note**

*Nsc turns off a volume's **modify** flag before it destages the volume, making the volume read-only (see [modify](#)). Before you run the `nsc ... destage` command, you can avoid this by running the `gbl-ns-vol reimport-modify` command.*

**Guidelines:
Correcting a Problem
at an NFS-Metadata
Share**

If a volume's [metadata share](#) supports NFS and that NFS mount is hung, all of the volumes in the same volume group will eventually become unusable. The [show volume-group](#) command shows the volume-group assignments for your volumes. You can use the [volume-group](#) clause in this command to destage those specific volume groups, then [reload](#) the ARX to initiate a failover. The destaged volumes must re-import after this failover, but no other volumes are affected. NFS clients must un-mount and re-mount the NFS front-end exports for these volumes; CIFS clients are unaffected by the re-import. This re-establishes storage service on the peer ARX with minimal disruption to clients.

Sample

```
bstnA# nsck archives destage volume /mktg
```

```
Volume /mktg is in use by CIFS global service 'fs10.medarch.org'.
```

```
This operation will remove entries for all shares in the volume  
from the namespace metadata. To reimport a destaged share,  
enable the share.
```

```
% WARNING: Volume /mktg in namespace wwmed is in use by global  
services.
```

```
Destaging the volume will disrupt all clients using this volume.
```

```
Destage the volume anyway? [yes/no] yes
```

```
bstnA# ...
```

```
destages the '/mktg' volume in the 'archives' namespace.
```

Related Commands

```
show namespace  
show reports  
show external-filer  
enable \(gbl-ns-vol-shr\)
```

nsck ... migrate-metadata

Purpose Use the `nsck migrate-metadata` command to move a managed-volume's metadata from one share to another.

Mode `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `nsck name migrate-metadata volume volname target filer-name {nfs3 | nfs3tcp | cifs} path`

name (1-30 characters) is the name of the namespace.

migrate-metadata is required.

volume volname (1-256 characters) is the chosen managed volume.

target filer-name (1-64 characters) is the new filer or file server for the volume's metadata. Use the [show external-filer](#) command for a list of configured filers.

nfs3 | nfs3tcp | cifs is the protocol for accessing the above filer (NFSv3 over UDP, NFSv3 over TCP, or CIFS). This can be different from the protocol(s) for the managed volume, though you cannot choose a CIFS share for a managed volume in an NFS-only namespace.

path (1-1024 characters) is the path to the back-end filer share, or a CIFS-share name (possibly with a sub-path). Use forward slashes (/) for Unix exports or CIFS shares.

Default(s) None.

Guidelines This applies to a managed volume only, not to a [direct](#) volume.

This stops client access to the managed volume while the metadata migration proceeds. The CLI asks for confirmation before moving the volume's metadata; enter **yes** to continue.

The migration occurs in stages for maximum protection of the volume's metadata. It copies all metadata to the new share, verifies its integrity, and brings the volume back online before it deletes the metadata from the old share. If the job is canceled or if it fails before the final transition, the managed volume comes back online with its original metadata share.

Very large volumes may take a long time for their metadata to migrate. The command returns immediately, providing you with the name of a detailed report. You can continue using the CLI while the migration occurs in the background. The [show nsck](#) command shows the current status of one or more nsck operations.

The migration report is named "migrate_metadata.nsck-job-id.rpt." Use [show reports](#) to list all reports, including this one. To follow the progress of the migration, you can use [tail reports report-name](#) follow. For a sample report, see [Figure 37.1 on page 37-13](#).

To cancel the metadata migration (and return the volume to service with its original metadata share), use [cancel migrate-metadata](#).

The [metadata share](#) command establishes a metadata share for a managed volume. If you decide later to move the metadata to a new share, you can use this command (`nsck ... migrate-metadata`) to perform the metadata migration.

Sample bstnA# nsck wwmed migrate-metadata volume /acct target nas3 nfs3 /exports/meta7

Volume /acct is in use by NFS global service 'ac1.engsmoke.acopianet.com'.
Volume /acct in namespace wwmed is in use or being browsed by global services.

Migrating metadata for this volume will disrupt all clients accessing this volume through these services.
No other volume will be affected by this procedure.

Proceed with metadata migration? [yes/no] yes
Starting metadata migration for wwmed:/acct. 2162688 bytes to be transferred.
Detailed status contained in report: migrate_metadata.39.rpt on switch bstnA

migrates metadata for the 'wwmed~/acct' volume to a share on the "nas3" filer.
See [Figure 37.1](#) for a sample report.

Related Commands [metadata share](#)

```

nsck ... migrate-volume

Purpose Every ARX volume resides in a *volume group*, where it shares CPU and memory resources with the other volumes in the same group. Each volume group is a single failure domain, where certain catastrophic failures affect the other volumes in the same group but do not affect any volumes outside the group. As your deployment grows, you may want to redistribute your volumes to mitigate possible down time. Use the `nsck migrate-volume` command to move a volume from one [volume-group](#) to another.

Mode `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `nsck name migrate-volume volname volume-group id [check-limits]`

name (1-30 characters) is the name of the namespace.

migrate-volume volname (1-256 characters) is the volume to migrate.

volume-group id chooses the destination volume group. Use the [show volume-group](#) command to show all currently-existing volume groups and their volumes. Choose a volume group from the same namespace as the source volume, or choose a new one. This volume group must be able to support the new volume without exceeding any of its licensed limits. To confirm that the migration meets all these criteria, you can use the **check-limits** option (below).

check-limits verifies that the volume migration is possible without actually migrating the volume. You can use this option to run a test before you perform the migration. This checks the licensed limits at the destination volume group and any other possible obstacles for a successful migration.

Default(s) None.

Guidelines This command stops client access to the volume until the migration is complete. The CLI lists all affected front-end services and asks for confirmation; enter **yes** to continue.

A volume cannot migrate while it is importing files from its back-end shares. (You invoke volume import with the [enable \(gbl-ns, gbl-ns-vol\)](#) command.) The import must be complete before you move the volume to another volume group.

If you run multiple volume migrations at the same time, they must all be to different volume groups. A volume group can only accept one migrating volume at a time.

Very large volumes may take a long time to migrate. The command returns immediately, providing you with the name of a detailed report. You can continue using the CLI while the migration occurs in the background. The [show nsck](#) command shows the current status of the migration, along with the status of all other nsck operations. After the nsck job is complete, the front-end service(s) require a few additional seconds before they allow client access to the volume.

The migration report is named “`migrate_volume_group.nsck-job-id.rpt.`” Use [show reports](#) to list all reports, including this one. To follow the progress of the migration, you can use [tail reports report-name](#) follow. For a sample report, see [Figure 37.2 on page 37-15](#).

To cancel the volume migration (and return the volume to service in its original volume group), use [cancel migrate-volume](#).

Samples bstnA# nsck medarcv migrate-volume /test_results volume-group 3
check-limits
 % INFO: Volume-group migration limit checking passed.

confirms that it is possible to migrate the 'medarcv~/test_results' volume to volume group 3.

bstnA# nsck medarcv migrate-volume /test_results volume-group 3

Volume /test_results is in use by CIFS global service 'ac1.medarch.org'.
 Volume /test_results in namespace medarcv is in use or being browsed by global services.

Migrating the volume to a different Volume-Group will disrupt all clients accessing this volume through these services.
 No other volume will be affected by this procedure.

Proceed with volume migration? [yes/no] yes
 Scheduling report: migrate_volume_group.40.rpt on switch bstnA

migrates 'medarcv~/test_results' to volume group 3. See [Figure 37.2](#) for a sample report. This is a direct volume, so the report does not include any information about metadata.

nsck ... rebuild

Purpose The namespace-check (*nsck*) utility finds and repairs inconsistencies between a managed volume's metadata and actual files on back-end storage. An *nsck rebuild* operation deletes all metadata and re-imports all shares. Use the *nsck rebuild* command to re-initialize all managed volumes in a namespace, or a particular volume.

Mode priv-exec

Security Role(s) storage-engineer or crypto-officer

Syntax *nsck name rebuild [volume volname] [force]*

name (1-30 characters) is the name of the namespace to rebuild. Use the [show namespace](#) command to see a list of configured namespaces.

volume volname (optional, 1-256 characters) limits the rebuild to the chosen volume (for example, '/home').

force (optional) indicates that you want to force the destage even if another *nsck* job is currently under way. You can force any *nsck* job with this option except [nsck ... migrate-metadata](#) or [nsck ... migrate-volume](#); you must cancel those jobs explicitly (with [cancel migrate-metadata](#) or [cancel migrate-volume](#)) before you can rebuild the volume.

Default(s) None.

Guidelines: Determining if a Rebuild is Necessary If clients get front-end-service (NFS or CIFS) failures for a particular managed volume, the volume's metadata might be inconsistent the files on the back end. As further indication of inconsistency, search through the syslog file for DB_RUNRECOVERY messages. Use [show logs](#) to view the current syslog, or use [grep syslog](#) to search the syslog for certain patterns. Use [show logs](#) to view all log files, including backups, in the logs directory.

You can use the [nsck ... report inconsistencies](#) command to check the namespace, volume, or share for inconsistencies without changing any metadata. To attempt to repair inconsistencies, you can use the [sync files](#) command to synchronize the metadata with actual files, or the [sync directories](#) command to find any new directories and add them to the metadata. If a sync fails, *nsck ... rebuild* is a last resort. This operation stops all volume processing, rebuilds all metadata, and re-syncs all filer subshares; this causes a complete service interruption.

Guidelines: Modify Flag Each managed volume has a "modify" flag that you can set with the *gbl-ns-vol modify* command. This flag, if raised, allows the volume to rename any imported files or directories with the same pathname as previously-imported files. If lowered, such files and directories are not imported *and* clients cannot write to the volume.

The *nsck ... rebuild* command lowers this flag for each managed volume that it rebuilds. By default, it keeps the flag lowered after the rebuild is over. This is a safety feature to avoid renamed files when they might not be expected. To allow modifications, you can run the *gbl-ns-vol reimport-modify* command for each desired volume. This command tells *nsck* to re-instate the *modify* flag after the rebuild.

**Guidelines: Directory
Mastership After the
Rebuild**

If your volume has tiered shares, where some shares reside on faster and/or more reliable filers than others, we recommend placing all of your *master directories* onto your Tier 1 shares. Whenever two or more directories have the same name and path, one is considered *master* and the others are called *stripes*. The volume's clients cannot access a directory if its master instance is unavailable from the back end, so it is important to keep the masters on reliable filers.

Use a [place-rule](#) to select all directories in the volume, place them onto one or more Tier 1 shares, and promote them to master. The rebuild process follows all directory-place rules during the re-import. Additionally, set all of your Tier 1 shares to [import priority 1](#), to force the volume to scan those shares before the lower-priority shares. This ensures that all master directories for the volume are on Tier 1 shares.

**Guidelines: Running
the Command**

The CLI prompts for confirmation before disabling the namespace or volume: you must answer **yes** to proceed with the rebuild operation.

The optional **force** flag is useful for working through a hung nsck job. An nsck job may hang if one of the back-end shares or filers goes offline at the wrong time.

All NFS clients that use the volume(s) must unmount and remount after the rebuild is finished.

Samples

```
bstnA# nsck ns rebuild
Reimport all shares in the namespace ns? [yes/no] yes
bstnA#
```

rebuilds the "ns" namespace.

```
bstnA# nsck archives rebuild force
forces a rebuild in the "archives" namespace.
```

```
bstnA# nsck archives rebuild volume /etc
rebuilds the "/etc" volume in the "archives" namespace.
```

[place-rule](#)

nsck ... report dir-structure

Purpose A managed volume's *metadata* is its background information about its files and directories, such as their physical locations on back-end filers. You can use the `nsck report dir-structure` command to get a report of a volume's directory structure from its metadata. This is faster than the full `nsck ... report metadata-only` command, and the report provides a quick overview of the volume's directory layout.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `nsck name report dir-structure [path] [norecurse] [summary] [outputfile outputfile]`

name (1-30 characters) is the namespace on which to report. Use the `show namespace` command for a list of configured namespaces.

path (optional, 1-256 characters) narrows the scope of the report to a specific virtual path in the namespace (for example, `/home/jrandom`). If you omit this, the command generates one report per volume.

norecurse (optional) specifies to not recurse into subdirectories during the report. The directory listing therefore only includes the root of the volume, or the *path* if you chose that option.

summary (optional) removes the table of directories from the report.

outputfile outputfile (optional; 1-255 characters) specifies a prefix for a customized file name (for example, `jrandom_dir.rpt`), as opposed to the default. Use the `show reports` command to display the file in the maintenance directory.

Default(s) *path* - the root of the namespace (all volumes).

outputfile outputfile - `'dir-structure.nsck-id.rpt.'` The *nsck-id* is a unique number assigned to each nsck job.

Guidelines The name of the nsck report appears after you issue the command. Use `tail` to follow the report as it is written. Use `show reports file-name` to read the report. You can search through the report with `grep`. To copy or delete it, use the `copy` or `delete` commands.

The non-summary report shows

- the configuration options chosen by this command,
- the back-end shares that hold the directories,
- a table of directories, where each directory appears in one row,
- a summary of the directory structure (maximum and average entries, files, links, and so forth amongst these directories), and
- a listing of total files, directories, and other high-level information.

The summary report omits the table of directories.

If you want to cancel the report before it finishes, use the `cancel nsck report` command.

For a full report of all files and directories in a managed volume, use the `nsck ... report metadata-only` command.

Samples bstnA# nsck medarcv report dir-structure /rcrds
 Scheduling report: dir_structure.34.rpt on switch bstnA
 bstnA# ...

shows the directory structure for the 'medarcv~/rcrds' volume. The report appears in 'dir_structure.34.rpt.' A sample appears below in [Figure 37.3 on page 37-19](#).

bstnA# nsck insur report dir-structure
 Scheduling report: dir_structure.43.rpt on switch bstnA
 bstnA# ...

shows the directory structure for all volumes in the 'insur' namespace. This produces a single report, , for the namespace's single volume. A sample appears in [Figure 37.4 on page 37-20](#).

nsck ... report inconsistencies

Purpose A managed volume's *metadata* is its background information about its files and directories, such as their physical locations on back-end filers. If a client has direct access to one of the volume's back-end shares (that is, access that does not go through the volume), the volume's metadata is likely to be inconsistent. Metadata inconsistencies can also occur in a multi-protocol (NFS and CIFS) volume without any client intervention: on a multi-protocol filer, a file or directory name may differ between NFS and CIFS.

Use the `nsck report inconsistencies` command to find (but not repair) any inconsistencies in a namespace's metadata, or to prove that there are none.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `nsck name report inconsistencies [path] [share share-name] [norecurse] [nofilehandles] [multi-protocol] [outputfile outputfile]`

name (1-30 characters) is the namespace on which to report. Use the [show namespace](#) command for a list of configured namespaces.

path (optional, 1-256 characters) narrows the scope of the report to a specific virtual path in the namespace (for example, `/home/jrandom`).

share *share-name* (optional, 1-64 characters) limits the report to a single share in the volume.

norecurse (optional) specifies to not recurse into subdirectories during the report.

nofilehandles (optional) specifies to not validate file handles during the report.

multi-protocol (optional) focuses the report on inconsistencies between NFS names and CIFS names. This only applies to a volume in a multi-protocol (NFS and CIFS) namespace.

outputfile *outputfile* (optional; 1-255 characters) specifies a prefix for a customized file name (for example, `jrandom_inconsistencies.rpt`), as opposed to the default. Use the [show reports](#) command to display the file in the maintenance directory.

Default(s) *path* - the root of the namespace (all volumes).

outputfile *outputfile* - `'inconsistencies.nsck-id.rpt.'` The *nsck-id* is a unique number assigned to each nsck job.

share-name - all shares in the volume.

Guidelines The name of the nsck report appears after you issue the command. Use [tail](#) to follow the report as it is written. Use [show reports file-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the [copy](#) or [delete](#) commands.

The report shows various types of inconsistency:

- Metadata disagrees with actual files or directories on the back-end filers,
- A file or directory name matches an alternate “8.3” name on a back-end-CIFS share, or
- A file or directory name matches a filer-generated name (FGN) on a back-end share that supports both CIFS and NFS.

The [ARX CLI Maintenance Guide](#) discusses all of these inconsistency types in detail, and describes methods for addressing each inconsistency type.

If this operation finds any metadata inconsistencies, you can use [sync files](#) to synchronize the metadata with the filer.

If you want to cancel the report before it finishes, use the [cancel nsck report](#) command.

Guidelines: This report also describes any network issues, filer issues, or other unusual problems that temporarily prevent a full listing. These are denoted by the following codes:
Transitional States

- MF - The file is being migrated from one share to another, so it is in a transitional state. If there is an additional FF (Found-File) entry for the same file, the FF indicates that it found an extra copy of the file while it existed (for an instant) on both the source share and the destination share. You can probably disregard the FF state for that file. Run the report later for an accurate assessment of its metadata consistency.
- NL - The nsck software could not lock the parent directory, typically due to heavy client activity. Without this lock, numerous changes (such as file additions, edits, and deletions) can be underway, making it possible to mistakenly assume an inconsistency. Run the report later on this directory to get an accurate measure of its inconsistencies. You can use the optional *path* in this command to focus on a particular path in the volume.
- FE - The nsck software lost contact with the filer during the report. Check for connectivity issues with this filer. Once the problem is corrected, run the report again.
- FO -The filer is offline. Address the problem at the filer and rerun this report.
- DC - A client issued a “delete-on-last-close” command for this file, but the filer deleted it early. EMC Celerra servers have shown this behavior in lab testing. The client application has already announced its intention to delete the file, so this condition is cleared when the client application closes the file.

Samples bstnA# nsck wwmed report inconsistencies
Scheduling report: inconsistencies.2.rpt on switch bstnA
bstnA# ...

nsck ... report metadata-only

Purpose A managed volume's *metadata* is its background information about its files and directories, such as their physical locations on back-end filers. Use the `nsck report metadata-only` command to show a namespace's or volume's metadata.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `nsck name report metadata-only [path] [share share-name] [norecurse] [outputfile outputfile]`

name (1-30 characters) specifies a namespace on which to report. Use the [show namespace](#) command for a list of configured namespaces.

path (optional, 1-256 characters) narrows the scope of the report to a specific managed volume or path in the namespace (for example, `/eng/share`).

share share-name (optional, 1-64 characters) limits the report to a single share in the volume.

norecurse (optional) specifies to not recurse into subdirectories during the report.

outputfile outputfile (optional, 1-255 characters) specifies a prefix for a customized file name (for example, `'jrandom_inconsistencies.rpt'`), as opposed to the default. Use the [show reports](#) command to display the file in the maintenance directory.

Default(s) *path* - the root of the namespace (all managed volumes).

share-name - all shares in the volume.

outputfile outputfile - `'metadata_only'`

Guidelines When a share is first imported into a managed volume, a report similar to this one is generated. You can compare that report to this one to see the effects of policy on your file locations. The import reports are accessible through [show reports](#). Their names have the following formats:

```
import.share-id.share-name.job-id.rpt
```

Use the [find](#) command to show the physical location of a single file.

The name of the nsck report appears after you issue the command. Use [tail](#) to follow the report as it is written. Use [show reports file-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the `copy` or `delete` commands.

If you want to cancel the report before it finishes, use the [cancel nsck report](#) command.

You can use the [nsck ... report dir-structure](#) command for a faster report that focuses on the volume's directory structure.

Guidelines: Report Content The report lists all files (labeled FL) and directories (labeled DR) recorded in the volume's metadata. An SL indicates that the file or directory is actually a symbolic link, or symlink. Most of the other labels indicate a naming issue; you can examine these thoroughly with the [nsck ... report inconsistencies](#) command.

The NL condition is typically transitory; it indicates that the nsck software is currently unable to get a lock on the parent directory for the given file or directory. This typically indicates high client activity (such as file creates and deletes) in the parent directory, which may lead to temporarily-inaccurate metadata readings in the report. The volume updates its metadata as soon as it is able to get the lock.

Guidelines: File Tracking This identifies the back-end locations of all the volume's files as of now; for file locations in the past, you can use *file tracking*. This can be useful for finding the correct filer-backup tape for a lost or compromised file.

The file-tracking feature requires some configuration before you can make any file queries. Specifically, a managed volume requires a [snapshot rule](#) to regularly copy its configuration and metadata to a [file-history archive](#). After some copies of metadata have been archived, you can use the [show file-history virtual-service](#) command to query file locations at different dates.

Samples

```
bstnA# nsck wwmed report metadata-only
Scheduling report: metadata_only.5.rpt on switch bstnA
bstnA# ...
```

shows the metadata for the 'wwmed' namespace. The report appears in 'metadata_only.5.rpt.' A sample report appears in [Figure 37.7 on page 37-29](#).

```
bstnA# nsck archives report metadata-only /arch
```

checks the virtual path, '/arch,' in the archives namespace. Note that this path could span multiple volumes.

```
bstnA# nsck archives report metadata-only /arch share fs6
```

checks only the files from /arch that are stored on the 'fs6' share.

```
bstnA# nsck acopia3 report metadata-only outputfile 6-5mdata
Scheduling report: 6-5mdata.15.rpt on switch bstnA
bstnA# ...
```

checks the 'acopia3' namespace and puts the report in a file, '6-5mdata.15.rpt.'

nsck ... report symlinks

Purpose A managed volume's *metadata* is its background information about its files and directories, such as their physical locations on back-end filers. The metadata also contains a flag for all NFS symbolic link (symlink) files. A multi-protocol (CIFS and NFS) volume uses this flag to support symlink de referencing for its CIFS clients. Use the `nsck report symlinks` command to show all of the NFS symlinks that are identified in the current volume's metadata.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `nsck name report symlinks [path] [share share-name] [norecurse] [outputfile outputfile]`

name (1-30 characters) specifies a namespace on which to report. Use the [show namespace](#) command for a list of configured namespaces.

path (optional, 1-256 characters) narrows the scope of the report to a specific managed volume or path in the namespace (for example, `/claims/common` for the `/common` directory in the `/claims` volume).

share share-name (optional, 1-64 characters) limits the report to a single share in the volume.

norecurse (optional) specifies to not recurse into subdirectories during the report.

outputfile outputfile (optional, 1-255 characters) specifies a prefix for a customized file name (for example, `jrandom_symlinks.rpt`), as opposed to the default. Use the [show reports](#) command to display the file in the maintenance directory.

Default(s) *path* - the root of the namespace (all managed volumes).

share-name - all shares in the volume.

outputfile outputfile - `'symlinks'`

Guidelines The name of the nsck report appears after you issue the command. Use [tail](#) to follow the report as it is written. Use [show reports file-name](#) to read the report. You can search through the report with [grep](#). To copy or delete it, use the `copy` or `delete` commands.

If you want to cancel the report before it finishes, use the [cancel nsck report](#) command.

-
- Guidelines: Report Content** The report lists all symlinks (labeled SL) recorded in the volume's metadata. For each symlink, one of the following codes provides some more information:
- RF indicates that the symlink resolves to (or points to) a file.
 - RD shows that the symlink resolves to a directory.
 - RS means that the symlink resolves to another symlink.
 - RX indicates a symlink error: the symlink points to a non-existent file or directory.
 - ER indicates an error in querying the filer for symlink information. The report includes specific error information in parentheses.
- The NL condition is typically transitory: it indicates that the nsck software is currently unable to get a lock on the parent directory for the given file or directory. This typically indicates high client activity (such as file creates and deletes) in the parent directory, which may lead to temporarily-inaccurate metadata readings in the report. The volume updates its metadata as soon as it is able to get the lock.
- Sample** `bstnA# nsck insur report symlinks outputfile insur_symlinks`
 Scheduling report: `insur_symlinks._claims.rpt` on switch `bstnA`
`bstnA# ...`
 shows all symlinks in the 'insur' namespace. The report appears in 'insur_symlinks._claims.rpt.' A sample report appears in [Figure 37.8](#).

nsck ... sync directories

Purpose	If someone goes around a managed volume to directly create a directory on a back-end filer, the volume metadata does not include the new directory. The volume's clients therefore cannot see or use the new directory. (This may be necessary for directories with special features that can only be provisioned at the filer itself, such as disk quotas.) Use the <code>nsck ... sync directories</code> command to find any new subdirectories under a known directory. This is equivalent to the sync directories command.
Modes	priv-exec
Security Role(s)	storage-engineer or crypto-officer
Syntax	<code>nsck namespace sync directories dir-path [share share-name]</code> <i>namespace</i> (1-30 characters) specifies the namespace to sync. Use the show namespace command for a list of configured namespaces. <i>dir-path</i> (1-256 characters) narrows the scope of the sync operation to a specific managed volume and path (for example, "/vol/var/log"). The path must describe a valid volume in the namespace, or one of its subdirectories. Use forward slashes (/) for NFS or CIFS paths. <i>share share-name</i> (optional, 1-64 characters) limits the sync and repair to a single share in the volume.
Default(s)	<i>share share-name</i> is unspecified, so all shares in the volume are synchronized and repaired.
Guidelines	This invokes the same software used by the sync directories command. Follow the Guidelines for that command.
Sample	<pre>bstnA# nsck medarcv sync directories /lab_equipment path / Scheduling sync directories operation on switch bstnA, report name: sync.9._lab_equipment.rpt bstnA# checks for unrecorded directories in the root of the "medarcv~/lab_equipment" volume.</pre>
Related Commands	sync directories show sync wait-for sync cancel sync clear sync nsck ... report inconsistencies show namespace show reports nsck ... rebuild

nsck ... sync files

Purpose If a file changes on a back-end filer without the managed volume's awareness, the volume metadata is *inconsistent* for that file. Use the `nsck ... sync files` command to report on metadata inconsistencies and repair them. This is equivalent to the [sync files](#) command.

Modes priv-exec

Security Role(s) storage-engineer or crypto-officer

Syntax `nsck namespace sync files dir-path [share share-name] [recurse] [rename-files]`

namespace (1-30 characters) specifies the namespace to sync. Use the [show namespace](#) command for a list of configured namespaces.

dir-path (1-256 characters) narrows the scope of the sync operation to a specific managed volume and path (for example, "/vol/var/log"). The path must describe a valid volume in the namespace, or one of its subdirectories. Use forward slashes (/) for NFS or CIFS paths.

share share-name (optional, 1-64 characters) limits the sync and repair to a single share in the volume.

recurse (optional) causes the sync operation to descend into subdirectories.

rename-files (optional) determines that, if a file-collision is discovered, the sync operation can rename the newly-discovered file. All collisions and renames are included in the sync report.

Default(s) *recurse* is off; the sync only examines the *dir-path* without descending into any child directories.

rename-files is off; collisions are noted in the sync report, and the metadata is not repaired.

share share-name is unspecified, so all shares in the volume are synchronized and repaired.

Guidelines This invokes the same software used by the [sync files](#) command. Follow the Guidelines for that command.

Sample

```
bstnA# nsck wwmed sync files /acct recurse
Scheduling sync files operation on switch bstnA, report name:
sync.1._acct.rpt
bstnA#
```

repairs the top-level directory in the "wwmed~/acct" volume. This descends into child directories but does not repair any renamed files that have collided with known files.

Related Commands [sync files](#)
[show sync](#)
[wait-for sync](#)
[cancel sync](#)
[nsck ... report inconsistencies](#)
[show namespace](#)
[show reports](#)
[nsck ... rebuild](#)

show nsck

Purpose Use the `show nsck` command to show the current state of all nsck report, nsck rebuild, and sync operations.

Modes (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show nsck [nsck-id | namespace name | all]`

nsck-id (optional) identifies one nsck or sync job to show. The job ID appears if you run `show nsck` without any options.

name (optional, 1-30 characters) shows the nsck and/or sync job(s) in one namespace.

all (optional) shows a detailed view of all nsck and sync jobs.

Default(s) None.

Guidelines If you do not include any of the options, the command displays the nsck and sync records for all namespaces.

The `show nsck` command shows the operation ID (Op ID), the type of operation (Op Type), the namespace and path where the operation is running, and the current Status of the operation. Possible status lines appear below.

The `show nsck all` and `show nsck nsck-id` commands add detail to the output, including the name of the job report and the switch where the report resides. The latter is useful in redundant pairs, where a report could be generated on either peer.

The report data from the nsck commands is stored in a `.rpt` file in the “reports” directory. Use [show reports](#) to view files from this directory.

Use the [clear nsck](#) command to clear one nsck job (or all nsck jobs). The [clear sync](#) command clears sync jobs.

Guidelines: Possible Status Conditions

Complete indicates a successful nsck operation.

Pending shows that the nsck operation is starting.

Rebuild in progress shows that the nsck operation is rebuilding a namespace or managed volume ([nsck ... rebuild](#)).

Destage in progress appears for the [nsck ... destage](#) command.

Report in progress indicates that the nsck job is writing a report, such as an inconsistencies report ([nsck ... report inconsistencies](#)) or metadata report ([nsck ... report metadata-only](#)).

Cancelled means that someone stopped the nsck operation.

Migrate in progress (x%) indicates that someone is migrating a managed-volume's metadata from one metadata share to another. The percentage shows the progress of the migration.

Cancel in progress appears if someone stopped the metadata migration.

Synchronizing appears for the [sync files](#) command.

Pending Cancel and then

Canceling appears if someone stopped the synchronization job with the [cancel sync](#) command.

Guidelines: Possible Errors

Any of these Status comments indicate that the nsck job failed.

Error: Path not found - A virtual tree has a file or directory that is missing from its physical counterpart.

Error: Out of memory - The namespace software ran out of memory during the nsck operation.

Error: Temporary database - The namespace software encountered an error creating, opening, or deleting a temporary database.

Error: Resolving database entry - An error occurred while resolving an entry in the operation's temporary database.

Error: Bad storage type - The namespace software could not determine whether a file-system entry was a file or a directory.

Error: Attributes not found - The namespace software failed to access file attributes from one of the back-end-directory trees.

Error: Incomplete - The switch rebooted before the nsck job was finished.

Error: Incomplete at force time - An [nsck ... rebuild force](#) interrupted the nsck job.

Error: Bad report type specified - The user specified an invalid report name in the nsck command.

Error: Migration failed - The metadata migration failed. All metadata still resides on its original share. You can use the [nsck ... migrate-metadata](#) command to invoke a metadata migration.

Error: Unable to open report - This is an internal error. Contact customer support.

Samples `bstnA# show nsck`

displays the state of the latest nsck and sync operations for all namespaces.
[Figure 37.9 on page 37-38](#) shows sample output.

`bstnA# show nsck namespace medarcv`

displays the state of the latest nsck/sync operations for the “medarcv” namespace.
[Figure 37.10 on page 37-39](#) shows sample output.

`bstnA# show nsck 1`

shows details about the nsck operation with ID 1. See [Figure 37.11 on page 37-39](#) for sample output.

```

show sync

Purpose Use the `show sync` command to show the results of all sync operations.

Modes (any)

Security Role(s) `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

Syntax

```
show sync {files | directories}
show sync {files | directories} namespace
show sync {files | directories} namespace volume vol-path
show sync {files | directories} namespace volume vol-path path
path
```

files | directories is a required choice. This selects the type of sync operation to show.

namespace (optional, 1-30 characters) is the name of a namespace. Use [show namespace](#) for a list of all configured namespaces. If you omit this (and all other options), the output includes all recorded sync-files or sync-directories operations.

vol-path (optional, 1-1024 characters) focuses on a particular volume. Use forward slashes (/) for all volumes, including CIFS.

path (optional, 1-1024 characters) narrows the focus further, to a particular path within the volume. As with volumes, use forward slashes in all paths.

Default(s) None.

Guidelines This command shows all sync operations, past and present. They are organized by namespace, volume, and in-volume path where the sync ran:

Namespace is a namespace where at least one sync operation occurred.

Volume is one volume where someone invoked a sync.

Path is the path where a sync operation occurred. This contains details about the operation:

Options are “recurse” and/or “rename-files.” This does not appear unless the user selected one of these options. They are options in the [sync files](#) command only.

Type appears only for auto-sync operations. An auto-sync occurs only in a volume that is enabled to run them with [auto sync files](#). A client triggers an auto-sync operation by getting an error that indicates metadata inconsistency. The value for this field is “Automatic.”

Status is “Pending,” “Synchronizing,” “Pending Cancel,” “Canceling,” “Success,” or “Failed.” A typical sync operation goes from “Pending” to “Synchronizing” to “Success.” Use the [cancel sync](#) command to cancel the sync operation. For details on the sync operation’s progress, you can look at the sync report, described below.

Report Name is the name of a detailed report about the sync operation. You can use the [show reports](#) command to view the report.

Share only appears if the share was specified (see the documentation for [sync files](#) or [sync directories](#)).

Guidelines (Cont.)

Lost Items are the files or directories that were recorded in metadata but are missing from the back-end filer.

Found Items are the reverse: these were found on the filer and needed to be added to the metadata.

Synchronized Items is the total repaired files and directories. Ideally, this should be the sum of the lost and found items above.

Processed Items is the total number of files and directories processed.

This output grows with every run of the `sync files` or `sync directories` command. Use `clear sync` to clear all sync operations from this output (without deleting any of the detailed sync reports; use `delete reports` to remove those).

Samples

`bstnA# show sync files`

displays the state of all sync-files operations for all namespaces. [Figure 37.12](#) shows sample output.

`bstnA# show sync directories`

displays the state of all sync-directories operations. [Figure 37.13 on page 37-42](#) shows sample output.

`bstnA# show sync files medarcv volume /rcrds`

displays the state of all sync-files operations for a CIFS volume, "medarcv~/rcrds." [Figure 37.14 on page 37-42](#) shows sample output.

sync directories

Purpose If a directory appears on a back-end filer without the managed volume's awareness, the volume metadata is out-of-sync for that directory. This may occur for new directories that cannot be created from a client interface, such as NetApp qtrees. To use one of these special directories in a managed volume, you can create it on the back-end filer itself and then use the `sync directories` command to find it and add it to the volume's metadata.

Modes priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `sync directories namespace volume volume path path [share share-name]`

namespace (1-30 characters) specifies the namespace to sync. Use the [show namespace](#) command for a list of configured namespaces.

volume (1-1024 characters) specifies the namespace volume. All of the namespace's volumes appear in the `show namespace` output.

path (1-1024 characters) chooses a specific directory in the volume (for example, "var/log"). The sync operation looks for new directories under this path; it does not descend into any already-known subdirectories. This path is relative to the *volume* root, above. Use forward slashes (/) for NFS or CIFS paths.

share *share-name* (optional, 1-64 characters) limits the sync and repair to a single share in the volume.

Default(s) all shares in the volume are synchronized and repaired.

Guidelines In general, no changes should occur on a filer share that is imported into a managed volume, except changes that go through that volume. However, some directories require features that can only be applied directly on the back-end filer, such as NetApp qtrees. Use this command after one or more empty directories were added behind a managed volume.

As mentioned above, only empty directories can be found with the `sync` utility.

To find all new directories where they exist, use [nsck ... report inconsistencies](#). This command, `sync directories`, finds all new subdirectories under a known directory.

Very large directories may take a long time to synchronize. The command returns immediately, providing you with the name of a detailed report. You can continue using the CLI while the synchronization occurs in the background. The [show sync](#) command shows the current status of one or more sync operations. You can use the [wait-for sync](#) command to wait for the operation to complete. To cancel the operation, use [cancel sync](#).

Each sync operation generates a report named "sync.sync-job-id.volume.rpt," shown after you issue the command. Use [show reports](#) to list all reports, including this sync report. To follow the progress of the sync operation, you can use [tail reports report-name](#) follow.

If the sync/repair fails, use the [nsck ... rebuild](#) command to rebuild the volume (drop all volume metadata and re-import all back-end shares).

**Guidelines: Directory
Mastership After the
Sync**

The `sync directories` command uses the share priority set by the [import priority](#) command. That is, if two or more shares have the synchronized directory, and no other instance of that directory is already imported, the import priority determines which share has the master instance of the directory. Whenever there are two or more instances of a volume directory on the volume's back-end shares, one of them is *master* and the rest are called *stripes*. The stripe directory conforms to the attributes of the master.

Sample

```
bstnA# sync directories medarcv volume /lab_equipment path /acme share  
leased
```

```
Scheduling sync directories operation on switch bstnA, report name:  
sync.4._lab_equipment.rpt  
bstnA#
```

finds any new subdirectories under a particular directory and on a particular share: the /acme directory in the "medarcv~/lab_equipment~leased" share.

[Figure 37.15](#) shows a sample report, where one new directory, "/filters," was found and synchronized.

sync files

Purpose If a file changes on a back-end filer without the managed volume's awareness, the volume metadata is *inconsistent* for that file. Use the **sync files** command to report on metadata inconsistencies and repair them.

Modes priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax **sync files namespace volume volume path path [share share-name] [recurse] [rename-files]**

namespace (1-30 characters) specifies the namespace to sync. Use the [show namespace](#) command for a list of configured namespaces.

volume (1-1024 characters) specifies the managed volume. All of the namespace's volumes appear in the **show namespace** output.

path (1-1024 characters) narrows the scope of the repair to a specific path in the volume (for example, "var/log"). This path is relative to the **volume** root, above. Use forward slashes (/) for NFS or CIFS paths.

share share-name (optional, 1-64 characters) limits the sync and repair to a single share in the volume.

You can enter the final two options in any order, or you can omit them:

recurse causes the sync operation to descend into subdirectories.

rename-files determines that, if a file-collision is discovered, the sync operation can rename the newly-discovered file. All collisions and renames are included in the sync report, described below.

Default(s) **recurse** is off; the sync only examines the **dir-path** without descending into any child directories.

rename-files is off; collisions are noted in the sync report, and the metadata is not repaired.

all shares in the managed volume are synchronized and repaired.

Guidelines In general, no changes should occur on a filer share that is imported into a managed volume, except changes that go through that volume. However, some situations make this impossible:

- On reboot recovery, some filers replace files that were deleted shortly before the reboot.
- A filer-integrated Anti-Virus application may rename, remove, or create files on the filer itself.
- Some customers prefer to perform restore operations directly on their back-end filers.

Guidelines (Cont.) Whenever a client tries to access a file that has been removed by one of the above operations, the client system reports an internal error. For CIFS operations, messages appear in the syslog (labeled UNXFINDDNONE, UNXNOPATH, UNXOPENTYPE and/or UNXCRETYPE.), and the volume software sends an SNMP trap (vcifsNotfound or vcifsTypeMismatch). Use `grep` to search the syslog for a string. If a CIFS-only volume is configured to launch synchronizations automatically (with `auto sync files`), the manual `sync files` command is unnecessary.

Use this command after any of the above operations (filer reboot, filer restore, or virus detection at the filer). You can also use this in response to client complaints. To confirm any inconsistencies and find all directories where they exist, use `nsck ... report inconsistencies`.

Very large directories may take a long time to synchronize. The command returns immediately, providing you with the name of a detailed report. You can continue using the CLI while the synchronization occurs in the background. The `show sync` command shows the current status of one or more sync operations. You can use the `wait-for sync` command to wait for the operation to complete. To cancel the operation, use `cancel sync`.

Each sync operation generates a report named “`sync.sync-job-id.volume.rpt`,” shown after you issue the command. Use `show reports` to list all reports, including this sync report. To follow the progress of the sync operation, you can use `tail reports report-name` follow.

If the sync/repair fails, use the `nsck ... rebuild` command to rebuild the managed volume (drop all volume metadata and re-import all back-end shares).

Guidelines: This command also probes for NFS symbolic links (or symlinks) in a multi-protocol namespace. NFS symlinks are recorded in a multi-protocol volume’s metadata so that the volume can support them for its CIFS clients. (You can disable this CIFS-side de-referencing with the `cifs deny-symlinks` command, if desired).

Discovering Symlinks

Symlink discovery is unnecessary for most installations because symlinks are correctly flagged during import, and whenever an NFS client creates a new symlink. It is only necessary after a software upgrade adds CIFS symlink support to an existing multi-protocol volume, or if an NFS client created symlinks directly on a back-end filer.

Guidelines: Before the sync operation can sync any file, it must first verify that the file’s parent directory has synchronized attributes (permissions, ACLs, ownership, and so on). The parent directory’s attributes must be identical for all instances of the directory, in all of the shares behind the managed volume. If any of the managed volume’s shares are nearly out of space, this attribute-sync process may fail; this is because CIFS ACLs may be part of the directory attributes, and they require disk space.

Directory-Stripe Synchronization

This directory-attribute sync may result in SC or SI flags in the report:

- **SC** indicates that a previously unsynchronized directory was successfully synchronized by this command. The managed-volume software does this in the background, so it is rare to see this in the report for a manual sync operation.
- **SI** indicates that the sync operation attempted to sync a directory’s attributes, and the directory-attribute synchronization failed. This indicates that one of the managed volume’s shares is out of space. You can use `show namespace` to find the full share. You can access the filer directly to add more space, or use a `place-rule` with a `source` share to drain some files off of the full share. Then the managed-volume software synchronizes the directory attributes in the background, and this condition clears.

**Guidelines: File
Mastership After the
Sync**

The `sync files` command uses the share priority set by the `import priority` command. That is, if two or more shares have the same file at the same path, and no other instance of that file is already imported, the share with the better import priority wins the master instance of the file. The volume renames the other file(s) or fails the sync operation, as determined by the `rename-files` flag.

This is only relevant if you synchronize multiple shares. If you synchronize a single share, its files can only collide with already-imported files. An already-imported file is always master over a newly-imported file.

Samples

```
bstnA# sync files wwmed volume /acct path /
Scheduling sync files operation on switch bstnA, report name:
sync.1._acct.rpt
bstnA#
```

repairs the top-level directory in the “wwmed~/acct” volume. This does not descend into child directories, nor does it repair any renamed files that have collided with known files.

```
bstnA# sync files wwmed volume /acct path /jsmith recurse
Scheduling sync files operation on switch bstnA, report name:
sync.2._acct.rpt
bstnA#
```

recursively repairs the entire /jsmith directory in the “wwmed~/acct” volume.

```
bstnA# sync files medarcv volume /rcrds path / recurse rename-files
Scheduling sync files operation on switch bstnA, report name:
sync.3._rcrds.rpt
```

recursively repairs the root directory (/) in a CIFS volume, “medarcv~/rcrds.” [Figure 37.16 on page 37-48](#) shows a sample report, where a missing file, “/copyRandomx.exe,” was found and synchronized. Two additional files were also newly-discovered and synchronized.

sync subshares from-namespace

Purpose A *subshare* is a CIFS share (along with its ACL) that is nested under an imported CIFS share. Use the `sync subshares from namespace` command to discover all of the CIFS subshares behind a managed volume and then share them from a front-end service. This synchronizes the CIFS subshares between back-end filers and the front-end service.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `sync subshares from-namespace ns volume vol to-service fqdn [expose-hidden] [tentative]`

ns (1-30 characters) is the namespace for the sync operation. The namespace must support CIFS.

vol (1-1024 characters) specifies a managed volume with subshares. This command finds all CIFS subshares in all of the back-end shares behind this volume. It also replicates any subshares that are not already identical on those back-end shares. The command replicates the subshare name, directory path (relative to the share root), and ACL on each back-end filer that needs it.

fqdn (1-255 characters) is the target CIFS service to export all of the subshares found in the above volume.

expose-hidden (optional) causes the command to use a different front-end name for any subshares that are “hidden” on their back-end filers. A CIFS share is hidden from Windows-network views by adding a dollar-sign (\$) to the end of the share name (for example, “mybooks\$”). This option causes the operation to use an “exposed” front-end subshare for all such hidden subshares, without the dollar suffix (“mybooks”). Clients of the CIFS service can therefore see the shares.

This option does not expose any hidden subshares that may have been generated by the ARX, such as “_acopia_mybooks_4\$.”

tentative (optional) finds all of the subshares behind the volume and prints them in a report, but does not share them from the CIFS service.

Default(s) `None`.

Guidelines This operation is only effective in volumes that support CIFS and filer subshares. Subshares require special processing and configuration in order to be supported by the ARX. By default, if a CIFS client connects to a subshare on the ARX, the managed volume connects to the root of the filer share and then changes to the subshare directory from there. Since the volume connects to the root share, the ACL at that share is used to determine client-access privileges. This bypasses any share-level ACL that may be defined for the filer subshare.

You can configure a managed volume so that it passes a client connection from a front-end subshare directly to the back-end subshare, thereby allowing the filer to enforce its subshare ACLs. Use the `gbl-ns-vol filer-subshares` command to prepare a CIFS volume for subshare support, and then use this command to share all filer subshares out through a front-end CIFS service. (You can also use the `export (gbl-cifs) ... filer-subshare` command to share out a single subshare at a time.)

This command replicates all subshares, so that they have the same share names, ACLs, and directory names on all of the volume's shares. The *subshare-replication* process creates a sync report with the results. The name of the report appears after you issue the command. Use `show reports report-name` to see it.

To add a new subshare to a running CIFS service, follow the procedure outlined in the *Guidelines* of the `filer-subshares` command.

**Guidelines:
Preparation for
NetApp/EMCs Where
You Want Free-Space
Quotas**

If the volume is backed by any NetApp filers or EMC servers and you plan to support free-space quotas on them (see `freespace cifs-quota`), prepare the subshares directly on the filer *before* you invoke this command. The subshare-replication process does not create NetApp qtrees or EMC quota trees, and those special directories are required to support free-space quotas. Before you run subshare replication with this command, access the filers directly and

- (on a NetApp) create one qtree per subshare, or
- (on an EMC) ensure that the imported share is a File System with one quota tree per subshare.

See the *Guidelines: Subshare Replication with Free-Space Quotas* section of the `filer-subshares` documentation. Then invoke this command to synchronize their share-level ACLs and other attributes.

Guidelines: Naming for Replicated Subshares

This operation replicates subshares between filers as needed. Subshare replication also occurs during share import, so it is not typically necessary for this command to repeat it. For cases where it is necessary, the volume replicates every subshare name, directory path (relative to the import-share root) and ACL. Replicated subshares use the same name as the source subshare, called the *native* subshare name, whenever possible.

The volume cannot use a native subshare name if any other CIFS share on the back-end filer is already using that name. This is called a subshare-name *collision*. For subshare-name collisions, the managed volume names the subshare with the following syntax:

```
_acopia_subshare_id$
```

where

- *subshare* is the native name of the original subshare.
- *id* is unique integer to identify the subshare. This is unique for every subshare behind the ARX and its redundant peer.
- \$, at the end of the share name, hides the subshare name from most network clients.

To prevent any such generated names on a volume's filers, you can use the *native-names-only* option in the [filer-subshares](#) command. The *native-names-only* option causes subshare replication to fail.

Guidelines: Repairing a Failed Subshare Replication

If this replication process fails for any subshare, the front-end subshare is “degraded:” clients cannot access the files in the unsynchronized back-end subshare(s). The [show cifs-service](#) all command shows the current status of the subshare-replication process, and whether or not any subshare is degraded. You can use this command's sync report to understand the problem, resolve the problem at the filer, and then use [sync subshares from-service](#) to re-run the subshare replication.

Sample

```
bstnA# sync subshares from-namespace medarcv volume /rcrds to-service
ac1.medarch.org expose-hidden
```

```
% INFO: Sync subshares operation completed. See report
'syncSshrVolToService_20100706010239.rpt' for more detail.
```

replicates all subshares in the “medarcv~/rcrds” volume, then shares them out to clients through the “ac1.medarch.org” service. [Figure 37.17 on page 37-53](#) shows a sample report.

sync subshares from-service

Purpose	A <i>subshare</i> is a CIFS share (along with its ACL) that is nested under an imported CIFS share. Use the <code>sync subshares from-service</code> command to send CIFS subshares from a front-end CIFS service to all of the filers behind it. This is useful for repairing a degraded subshare.
Modes	priv-exec
Security Role(s)	storage-engineer or crypto-officer
Syntax	<code>sync subshares from-service <i>fqdn</i> to-namespace <i>ns</i> volume <i>vol</i> [tentative]</code>

fqdn (1-255 characters) is the FQDN for a CIFS service with subshares. Use the [show cifs-service subshares](#) all command for a complete list of CIFS services with subshares.

ns (1-30 characters) is the namespace behind the above service.

vol (1-1024 characters) is a particular managed volume with subshares. If the CIFS service exports any subshares from this volume, this command replicates the subshare definitions at all filers behind the volume.

tentative (optional) prints a report about all of the changes the command would make, but does not replicate any subshare information from filer to filer.

Default(s) None.

Guidelines This operation is only effective in volumes that support CIFS and filer subshares. When you configure subshare support at the volume (with [filer-subshares](#)) and the volume's front-end export (with `export (gbl-cifs) ... filer-subshare`), a client that connects to the front-end subshare passes through the volume to the back-end subshare, so that the back-end filer can impose its subshare ACL. Without subshare support, a client that connects to a front-end subshare is passed through to the root of the back-end share, and the filer uses the root share's ACL.

The ACL must be identical on all back-end instances of a subshare, so that clients have the same access rules no matter which back-end subshare they need.

You can use this command, `sync subshares from-service`, to correct a possible problem with subshares. When you first enable a managed volume with subshare support, it discovers and replicates all of the subshares on its back-end shares. After you export a subshare through a front-end service at some *fqdn*, the `show cifs-service fqdn` command indicates whether or not this subshare-replication process succeeded. If the subshare is degraded, you can get a detailed report about the problem by running this sync command with its **tentative** flag. Then you can correct the problem at the back-end filers and run this sync command again, this time without the **tentative** flag, to retry the replication.

The command creates a sync report with the results. The name of the report appears after you issue the command. Use `show reports report-name` to see it.

To export subshares that are currently defined at the back-end filers, use the [sync subshares from-namespace](#) command. This is the reverse of the current command; it sends subshare definitions from the back-end filers to the front-end service.

**Guidelines:
Preparation for
NetApp/EMCs Where
You Want Free-Space
Quotas**

If the volume is backed by any NetApp filers or EMC servers and you plan to support free-space quotas on them (see [freespace cifs-quota](#)), prepare the subshares directly on the filer *before* you invoke this command. The subshare-replication process does not create NetApp qtrees or EMC quota trees, and those special directories are required to support free-space quotas. Before you run subshare replication with this command, access the filers directly and

- (on a NetApp) create one qtree per subshare, or
- (on an EMC) ensure that the imported share is a File System with one quota tree per subshare.

See the [Guidelines: Subshare Replication with Free-Space Quotas](#) section of the [filer-subshares](#) documentation. Then invoke this command to synchronize their share-level ACLs and other attributes.

**Guidelines: Naming
for Replicated
Subshares**

This operation replicates subshares between filers as needed. The volume replicates every subshare name, directory path (relative to the import-share root) and ACL. Replicated subshares use the same name as the source subshare, called the *native* subshare name, whenever possible.

The volume cannot use a native subshare name if any other CIFS share on the target filer is already using that name. This is called a subshare-name *collision*. For subshare-name collisions, the managed volume names the subshare with the following syntax:

```
_acopia_subshare_id$
```

where

- *subshare* is the native name of the original subshare.
- *id* is unique integer to identify the subshare. This is unique for every subshare behind the ARX and its redundant peer.
- \$, at the end of the share name, hides the subshare name from most network clients.

To prevent any such generated names on a volume's filers, you can use the `native-names-only` option in the [filer-subshares](#) command.

Sample

```
newptA# sync subshares from-service provmed.MEDARCH.ORG to-namespace  
provMed volume /mds tentative
```

```
% INFO: Sync subshares operation completed. See report  
'syncSshrServToVolume_201110030248.rpt' for more detail.
```

tentatively syncs the subshares in the “provmed.MEDARCH.ORG” service. This produces a report that lists the subshares that require synchronization: see the sample in [Figure 37.18 on page 37-57](#). The sample report shows missing subshares.

wait-for nsck

Purpose Use the `wait-for nsck` command to wait for an nsck operation to complete.

Mode (any)

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `wait-for nsck namespace [vol-path] [timeout timeout]`

namespace (1-30 characters) is the name of a namespace.

vol-path (optional, 1-4096 characters) identifies a particular managed volume in the namespace.

timeout (optional, 1-2096) is the timeout value, specified in seconds. If this timer expires before the nsck operation completes, the command exits with a warning.

Default(s) *timeout* - 0 (zero, meaning “wait indefinitely”)

Guidelines The `wait-for nsck` command waits for an nsck operation on a specified namespace or volume to complete.

To interrupt the `wait-for nsck` command before the nsck operation completes, press `<Ctrl-C>`.

If the command is waiting for `nsck ... rebuild`, it exits after the volume(s) are destaged and have started importing files and directories from back-end shares. This command only waits until clients have full access to their files, not until import is complete.

Sample `bstnA(gbl-ns[medarcv])# wait-for nsck medarcv timeout 60`
waits for a nsck operation to complete in the “medarcv” namespace. If 60 seconds elapse before the nsck operation is finished, the command exits.

Related Commands [clear nsck](#)

[terminal beta](#)

wait-for sync

Purpose Use the wait-for sync command to block the CLI until one or more sync operations completes.

Mode (any)

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `wait-for sync {files | directories} [timeout timeout]`
`wait-for sync {files | directories} namespace [timeout timeout]`
`wait-for sync {files | directories} namespace volume vol-path [timeout timeout]`
`wait-for sync {files | directories} namespace volume vol-path path path [timeout timeout]`

files | directories is a required choice. This selects the type of sync operation to await.

The ***namespace***, ***vol-path***, and ***path*** arguments mimic the ones used in the [sync files](#) or [sync directories](#) command. These identify one or more sync operations; if you omit all of them, the command waits for all sync-files or sync-directories operations on the switch.

namespace (1-30 characters) specifies a namespace where one or more sync operations are occurring.

vol-path (optional, 1-1024 characters) specifies a volume. Use forward slashes (/) for all volumes, including CIFS.

path (optional, 1-1024 characters) identifies a particular path that is being synchronized. As with volumes, use forward slashes in all paths.

timeout (optional, 1-2096) is the timeout value, specified in seconds. If this timer expires before the sync operation completes, the command exits with a warning.

Default(s) *timeout* - 0 (zero, meaning “wait indefinitely”)

Guidelines The wait-for sync command waits for a specified sync operation to complete. To interrupt the wait-for sync command, press <Ctrl-C>. Use [cancel sync](#) to cancel the sync operation altogether. The [show sync](#) command shows all sync-files or sync-directories operations.

Samples `bstnA# wait-for sync files timeout 60`
waits for all sync-files operations on the switch to complete. If they do not complete in 60 seconds, the command returns with a warning.

`bstnA(gbl-ns[medarcv])# wait-for sync directories medarcv timeout 300`
waits for all sync-directories operations in the “medarcv” namespace to complete. If they do not complete in 300 seconds, the command returns with a warning.

`bstnA> wait-for sync files wwmed timeout 120`
waits for all sync-files operations in the “wwmed” namespace to complete. If they do not complete in 120 seconds, the command returns with a warning.

Related Commands [sync files](#)
[sync directories](#)
[show sync](#)
[cancel sync](#)

Basic Troubleshooting Tools

This chapter contains reference information for using and tuning the System Logging (syslog) utility and other troubleshooting tools.

Log Components

A *log component* is a source of syslog messages, typically an internal process or group of processes. The table below is an alphabetical list of all log components, with a brief description and an indication of the board(s) where the software runs.

Log Component	Description
AFFINITY	Affimgrd and libaffin, which manage the assignment of internal processes to CPU cores.
AFN_NET	IPC Abstraction Layer, for communication between internal ARX processes.
API	API Services.
APP_RON_RTMD	RON Route Table Maintenance Daemon.
AT	AT Library. This is deprecated, so it is unlikely to yield any log messages.
AUTH_CONSOLE	Console Authentication. This component performs authentication for administrators who log into the Console (serial) port.
AUTH_HTTP	HTTP Authentication. This component performs authentication for administrators who access the GUI through HTTP.
AUTH_HTTPS	HTTPS Authentication. This component performs authentication for administrators who access the GUI through HTTP over SSL, or HTTPS.
AUTH_SSH	SSH Authentication. This component performs authentication for administrators who access the CLI through Secure SHell (SSH).
AUTH_TELNET	Telnet Authentication. This component performs authentication for administrators who access the CLI through Telnet.
AUTO_DIAG_CLI	Auto Diagnostics, which gathers input/output statistics and monitors for service degradation.
BESPD	Back-end Share Probing daemon, which periodically probes the shares behind ARX volumes and checks their health.
BOOTPD	BOOTP Daemon, or the boot-protocol server, which manages ARX boots and reboots.
CATALOG_INTERNAL	Message Catalog Internal Errors.
CHASS	Chassis Manager, which implements chassis operations such as 'reload,' 'firmware upgrade,' and hardware monitoring.
CHASS_LIB	Chassis Manager Library. The chassis manager implements chassis operations such as 'reload,' 'firmware upgrade,' and hardware monitoring.
CIFS_CLI	CIFS CLI.

Log Component	Description
CIFS_SHIM_LIB	Interface to metadata storage on CIFS filers. Metadata is data about managed-volume files, such as their locations on back-end filers.
CIFSCONFD	CIFS Configuration Daemon, which manages one front-end CIFS service.
CLI	Command Line Interface.
CLI_NFS_COPY	Copy to/from NFS namespace.
CLI_RUN_EXIM	Run exim4 from the CLI..
CLI_WIZARD	Initial Interview, which prompts with questions and performs initial configuration the first time the ARX boots.
CLUSTER	Not supported.
COMMON_DNAS	Common DNAS Messages.
COMMON_NIS	Common Network Information System (NIS) messages. NIS servers provide a lookup service for NFS servers, to manage large NFS access lists.
COMMONLIB	Not supported.
CORE	Core collector.
CRMD	Critical Resource Monitor Daemon, which makes HA failover decisions based on external filers, routers, etc.
DDBD	Distributed Database Library. This is for the internal database, which stores the ARX configuration. You can see the full configuration with 'show running-config' and 'show global-config'.
DEBUG	Internal debugging - used for development only.
DFPD	DNAS Fast Path Manager Daemon, which configures managed volumes in the NSM data plane.
DME	Policy Data Mover Engine (DME). This implements file migrations from one back-end filer to another.
DMOUNTD	Distributed Mount Daemon for NFS mounts.
DMSG_LIB	DNAS Message Library.
DNAS_IMPORT	DNAS Import Messages. An import occurs when a filer share is enabled in an enabled managed volume. This is the process of walking the directory tree of the share and recording all of its files and directories in managed-volume metadata.
DNAS_MD_MIGRATE	DNAS Metadata Migration, which moves managed-volume metadata from one external filer to another.
DNAS_PGRP	DNAS Process Group and NFS. DNAS, or Distributed NAS, is the internal name for namespace software.

Log Component	Description
DNAS_POLICY	Inline policy events that occur during normal volume processing, such as file creates, directory renames, and other client actions. This is off by default because it generates a great deal of log messages, enough to potentially affect client traffic.
DNAS_SINIT	DNAS Storage Initialization.
DNAS_SREMOVE	DNAS Storage Removal.
DNC_LIB	DNAS Configuration Library for NFS. DNAS is the internal name for namespace software.
DOMAIN_JOIN	Active Directory domain joining components, which join an ARX-CIFS service to a Windows domain.
DR	Disaster Recovery, which involves loading a configuration on a backup-ARX site and activating the configuration on command.
DT	Direct Transport processes. This is a high-speed inter-process communication (IPC) library.
EMAILHOME	Email home daemon and CLI commands.
ENVLIB	Environmental Library, for monitoring the hardware platform. This only applies to the ARX-500.
EVAL_NET_RESULT	The results of joining an Active Directory (AD) domain.
EXIMD	Exim Daemon, which sends RPC requests to the exim message-transfer agent. That agent sends SMTP (email) messages from the ARX to external devices.
FCN	File Change Notification, for API access to snapshotted configuration and metadata.
FCND	File Change Notification daemon which provides API access to snapshotted configuration and metadata.
FFP	Fast Filter Processor.
FFP_UTIL	Fast Filter Processor Library.
FFPD	Fast Filter Processor Daemon.
FILER_MGMT_LIB	Snapshot daemon filer operations library.
FREESPACEMONITOR	Free Space Monitor.
FT_CIFS_SHIM_LIB	Interface to metadata storage on CIFS filers. Metadata is information about files and directories in managed volumes, such as their locations on back-end filers.
FT_CLI	File Tracking CLI. These are the CLI operations for setting up a file-history archive and using it to track the location of managed-volume files over time.

Log Component	Description
FTD	File Tracking daemon. This is the process of sending volume metadata and configuration to an external file-history archive, and using that archive to track the location of managed-volume files over time.
GBL_LIB	Global Services Library, for NFS and CIFS service management operations.
GBL_SVCMGR	Global Service Manager, which starts and stops NFS and CIFS front-end services.
GBLSVC_CLI	Global Service CLI.
GUI	Graphical User Interface (GUI), also known as the ARX Manager.
HA_CLI	High Availability CLI, such as the 'redundancy' command.
HWAGENT	Hardware Agent, for startup, shutdown, and monitoring of hardware components.
IPC_EVENT_LIB	IPC Event Library, for communication between internal ARX processes. This is deprecated, so it is unlikely to yield any log messages.
IPC_EVENT_MGR	IPC Event Manager, for communication between internal ARX processes.
IPC_LIB	Internal software inter-process messaging library.
IPCMOND	IPC service monitoring daemon, for monitoring the communication between internal ARX processes.
IPMIUTIL	ipmiutil event collector. All log levels for this logging component go to the kernel.log file, not syslog.
KRBCONFD	Active Directory (AD) Configuration Daemon, for periodically monitoring DCs and selecting the active DCs for each Windows domain.
KRBDDNS	Dynamic DNS registration helper. This registers dynamic-DNS aliases for an ARX-CIFS service with a remote DNS server.
L2SW_DRV	Layer2 - Internal Switch Hardware. This only applies to ARX-500, ARX-2000, and ARX-4000 systems.
L2SW_LVL7	Layer2 - Internal Switch Software. This controls packet traffic over network interfaces, channel traffic and LACP, spanning-tree, and other low-level networking. This only applies to ARX-500, ARX-2000, and ARX-4000 systems.
LIBCIFS	CIFS client library, used for non-client access to CIFS file servers. For example, this library is used for policy-invoked migrations.
LIBCIFSAUTH	CIFS authentication library, for authenticating front-end CIFS clients and internal ARX processes that access back-end filers.
LIBCIFSXT	CIFS utility library, used in conjunction with LIBCIFS.

Log Component	Description
LIBEXIM	Exim Utilities messages.
LIBKDCLBSTATS	Kerberos load-balancing statistics.
LIBSDDL	CIFS Security Descriptor Definition Language translation library, which transforms binary Security IDs (SIDs) and descriptors into text strings. Callers to this library include the SID_CACHE, POLICY_SHADOW, and SUBSHRMGT processes.
LIBXSD	CIFS security-descriptor translation library, which processes can use to access the SID_CACHE daemon. The SID_CACHE daemon translates between Security IDs (SIDs) on various file servers and the group/user names in a Windows domain.
LICENSE	License monitoring daemon and CLI.
LIP_LIB	Logical IP Address Library. A logical IP address is an internal address that processes use to communicate to one another.
LOCBROKERD	IPC Location Broker for internal (process-to-process) RPC requests.
LOGMGRD	Logging Manager Daemon.
MANUF	Manufacturing Purposes only - Internal Switch Software.
MERGED	Layer2 - Merge FPGA Daemon.
MGMT_CLI	Management SLM - not supported.
MGT_DNAS_CONFIG	DNAS Configuration. DNAS, or Distributed NAS, is the internal name for namespace software.
MGT_RON_RTMD	Route Table Control Daemon. This checks gateway health and loads the best available routes into the OS route tables.
MGT_SVC_AGENT	Service Agent, which acts as a local agent for the central Service Manager (MGT_SVCMGR) process.
MGT_SVCMGR	Service Manager, used to start (and possibly restart) ARX processes.
MLBD	Metalog Block Device (MLBD) Controller, which manages the internal metalog subsystem. The metalog subsystem stores database-transaction logs for managed volumes.
MS_CLIENT	Microsoft RPC Services - High-level library used to interact with CIFS filers.
MS_RPC	Microsoft RPC Library - Low-level library used to interact with CIFS filers.
MTLDAEMON	Metalog Daemon. This is the process that records metalog (namespace-recovery log) data, on the local NVRAM hardware. This only runs on the ARX-500, ARX-2000, and ARX-4000.
NET	Network, or data-plane, processes.
NET_APP	Miscellaneous Application Events in the network software.

Log Component	Description
NET_CIFS	NSM CIFS Proxy.
NET_ERR_TRAP	Fastpath resource errors.
NET_HA	NSM HA.
NET_IPC_PROXY	NSM IPC Proxy, for communication between internal ARX processes on the control plane and on the data plane.
NET_LOG_PROXY	NSM Log Proxy.
NET_MSG	NSM Messaging between network processes.
NET_NFS	NSM NFS Proxy.
NET_OS	NSM Embedded Operating System.
NET_SLB	Server Load Balancing in the network software - not supported.
NET_STATS	NSM Statistics Collection.
NET_TCPSP	TCP Splicing.
NETBIOS	Netbios name service, which supports WINS.
NETSNMP	SNMP management on ARX-1500 and ARX-2500.
NFSCONFD	NFS Configuration Daemon, which manages one front-end NFS service.
NISD	NIS daemon messages. NIS servers provide a lookup service for NFS servers, to manage large NFS access lists. The NIS daemon queries all the configured NIS servers and caches the results of those lookups.
NLA	NETLOGON Agent, supports NTLM authentication of CIFS clients, but only for ARX CIFS services configured for constrained delegation.
NLM	NFS Network Lock Manager (NLM) Daemon. This implements the NFS NLM protocol, which manages file locks for NFS clients.
NMPIPE	Named Pipe, for communication between internal ARX processes (MS-RPC operations on CIFS IPC\$ named pipes).
NSCK	DNAS Namespace Check (NSCK), for examining and repairing managed-volume metadata. Metadata is managed-volume information about its files and directories, such as locations on back-end filers.
NSCKRPT	NSCK Report Messages.
NSM	NSM Shared Memory.
NSM_ROM	NSM ROM.
NTLMAGENTAPI	NTLM/NTLMv2 authentication library using ARX Secure Agent.
NTP	Network Time Protocol (NTP) subsystem to keep the ARX clock(s) synchronized with an external clock on the IP network.

Log Component	Description
NVRDAEMON	Non Volatile RAM (NVRAM) Daemon, which manages one or more mtlDaemons (see MTLDAEMON). An mtlDaemon records metalog (namespace-recovery log) data, on the local NVRAM hardware. This only runs on the ARX-500, ARX-2000, and ARX-4000.
OBJ_MGR	Object Manager Database.
OBJ_MGR_LIB	Object Manager Library.
OM	Object Manager (Distributed Database) process. This is for the internal database, which stores the ARX configuration. You can see the full configuration with 'show running-config' and 'show global-config'.
OMIO	Object Manager Record I/O Tracing. This tracing is for the internal database, which stores the ARX configuration. (You can see the full ARX configuration with 'show running-config' and 'show global-config'.).
OMTT	Object Manager Transaction Tracing. This tracing is for the internal database, which stores the ARX configuration. (You can see the full ARX configuration with 'show running-config' and 'show global-config'.).
PERSONALITY	Personality, which parses XML data transferred between internal processes.
POLICY	not supported.
POLICY_ACTION	Migration requests and responses. You can use this to diagnose migration issues, such as file matching and mismatching.
POLICY_CLI	not supported.
POLICY_PDP	Policy Decision Point - policy scheduler, which uses schedule configuration to trigger scans and other policy events.
POLICY_PEP	Policy Enforcement Point - policy scanning, events, rule-state processing, and rule info.
POLICY_SHADOW	Policy Shadow Volume, a read-only volume that contains replicas of all the files and directories on another volume.
PROBE	Probes for Monitoring and Controlling Subsystems.
PTW	Parallel Treewalk Library.
RELMGR	Release Manager, which stores software-release (.rel) files, unpacks them, prepares them for use on the ARX, and otherwise manages them.
RELMGR_CLI	Release Manager CLI commands. This is deprecated, so it is unlikely to yield any log messages.
REMOTE_CLI	Remote SSH CLI command execution, invoked through the CLI (with the 'rconsole' command) or the GUI.
REPLMGR	Replication Manager - Directs Data-Mover Engine (DME) file-migrations.

Log Component	Description
REPORT	Common subsystem for generating and viewing reports.
RESTARTDETECT	This determines if internal processes can be restarted after a failure.
RON	Resilient Overlay Network (RON) CLI operations.
RON_SPFD	Resilient Overlay Network (RON) Routing Daemon. This manages RON tunnels and determines the best route to remote ARX devices.
RON_VPND	Not supported.
ROOTD	Root Daemon, which performs internal Unix management that requires root-level privileges.
SCM_DSMD	DNAS Switch Monitor.
SEC_CONFIG	Security Configuration.
SEC_LOCAL	Security Local Enforcement.
SECURITY_CLI	Security CLI.
SECURITYD	Security Daemon.
SHMEM	Common, shared, memory-management subsystem. This is primarily used for gathering statistics.
SHRTOP	Share topology library - Used for various filer-subshare computations.
SID_CACHE	Security descriptor translation daemon (XSDD) and its caches. XSDD translates between Security IDs (SIDs) on various file servers and the principal (group or user) names in a Windows domain.
SLMCONFD	SLM Configuration Daemon - not supported.
SMGMT	Storage Management Library.
SMTP	Used for file transfer (through email), email events, and other email-related features.
SNAPD	Snapshot daemon, which coordinates snapshots on multiple filers behind an ARX volume.
SQMD	Redundant Pair Site Quorum Manager, which makes failover decisions based on cluster integrity.
SSB_LIB	SSB Library. The SSB is an internal mechanism for processes to communicate with one another.
SSBEVENTD	SSB Event Daemon. The SSB is an internal mechanism for processes to communicate with one another.
SSH	SSH configuration.
SSRM	Simple Share Resource Monitor, which monitors filers on behalf of the HA subsystem.

Log Component	Description
STATSD	Statistics Daemon, which exposes all ARX statistics to SNMP, the CLI, and the ARX manager (GUI).
STATSMON	Statistics monitoring.
SUBSHRMGT	Subshare management daemon and its client library. This manages filer subshares. A filer subshare is any CIFS share that is inside another CIFS share.
SVCMGR_LIB	SvcMgr Client Library. This is deprecated, so it is unlikely to yield any log messages.
SYNC_CLOCK	Log messages related to sync_clock and sntpc on ASMs - not supported.
SYNC_LIB	Shadow Synchronization Library, which supports a shadow volume (see POLICY_SHADOW).
SYSLOG_NG_GUARD	syslog-ng_guard, which monitors and (if necessary) reanimates the syslog-ng process. The syslog-ng process maintains the syslog file, possibly duplicating it to a remote peer.
TASK_LIB	Task Dispatcher Library - Internal framework used by internal processes for managing event-driven tasks and scheduled tasks.
TCMD	NSM Configuration Manager.
TCORED	NSM Core Dump Manager.
TIME	Not supported.
TRANFS	Transitional File System in DNAS.
TRANFSD	Not supported.
TXNMOND	Object Manager Transaction Monitor. This monitors the internal database, which stores the ARX configuration. (You can see the full ARX configuration with 'show running-config' and 'show global-config:').
UTIL	Fast Filter IPC Utilities, for communication between internal ARX processes and the Chassis Manager (see CHASS).
VCIFS	dNAS CIFS Proxy, which handles requests to volume software on behalf of CIFS clients.
WDOG	Watchdog, which performs internal health checks on ARX hardware such as the SSB. The SSB is an internal mechanism for processes to communicate with one another.
WMA	Windows Management Authorization (WMA) CLI Commands and Library.
WMI	Software Library for managing snapshots on back-end Windows servers using Windows Remote Management protocol (WinRM) and Windows Management Instrumentation (WMI).

additional-command

Purpose You can set up *auto-diagnostics* to regularly gather system information and send it to F5 Support. F5 can use this information to monitor your ARX from off site, watching for gradual loss of service or resource degradation. The information sent to F5 is the output from a series of CLI `show` commands. You can use the `additional-command` operation to add another `show` command to this collection of diagnostics.

Use `no additional-command` to remove an extra `show` command from auto-diagnostics.

Mode gbl-auto-diag

Security Role(s) storage-engineer or crypto-officer

Syntax `additional-command "show-command-string"`
`no additional-command "show-command-string"`

"show-command-string" (1-128 characters) is a valid `show` command in the ARX CLI, such as "show schedule." Surround the string with quotation marks (as shown) if it contains any spaces.

Default(s) No additional commands configured.

Guidelines This command adds an additional `show` command to the following list, which is always included in the auto-diags collection:

- `show clock`
- `show chassis`
- `show processors`
- `show processors usage`
- `show health`
- `show version`
- `show running-config`
- `show global-config`
- `show ron`
- `show namespace all`
- `show arp all`
- `show redundancy all`
- `show cores`
- `show statistics namespace ... fastpath all fastpath`
- `show policy details`
- `show cifs-service user-sessions all summary`
- `show statistics cifs authentication all`
- `show active-directory status detailed`
- `show statistics filer detailed`
- `show external-filer all`

Guidelines (Cont.) You can add up to 20 additional commands to the above list.

The `no` form of this command cannot remove any of these default `show` commands.

In a redundant pair of ARX machines (see [redundancy](#)), both peers collect and send auto-diagnostics information through E-mail. All of the commands in `gbl` mode are shared between the peers, so only the active peer collects `gbl`-mode information (such as [show global-config](#) and [show namespace all](#)). Both peers collect and send commands related to `cfg` mode (such as [show running-config](#) and [show ron](#)). This also applies to any commands you add to the collection with `additional-command`; if the command relates to `gbl` mode, it is only included in collections from the currently-active peer. If the command relates to `cfg` mode, it is included in auto-diagnostic collections from both peers.

Sample `prtlnDA(gbl-auto-diag)# additional-command "show channel summary"`
adds a new `show` command to the `auto-diags` collection for the “prtlnDA” chassis.

Related Commands [auto-diagnostics](#)

auto-diagnostics

Purpose	<p>F5 Support can monitor your ARX from off site, watching for gradual loss of service or resource degradation. This is accomplished by the ARX gathering diagnostic information and sending it (encrypted) as an E-mail attachment to F5. You can set the schedule, along with additional E-mail recipients and other options. Use the <code>auto-diagnostics</code> command to begin setting up auto monitoring by F5 Support.</p> <p>Use the <code>no auto-diagnostics</code> command to disable auto-diagnostics and remote monitoring.</p>
Mode	<code>gbl</code>
Security Role(s)	<code>storage-engineer</code> or <code>crypto-officer</code>
Syntax	<code>auto-diagnostics</code> <code>no auto-diagnostics</code>
Default(s)	<code>no auto-diagnostics</code>
Guidelines	<p>You must configure SMTP on the ARX before you enable auto-diagnostics, which uses E-mail as a delivery mechanism. Start with the <code>smtp</code> command in <code>cfg</code> mode.</p> <p>We recommend activating this feature so that F5 Support can monitor your ARX and watch for impending issues. This also provides F5 Support with you updated configuration data, so that you will not be required to provide this data at the beginning of a support call. This eases the burden of backing up your <code>running-config</code> and <code>global-config</code>; this provides a second backup for both configuration files.</p> <p>This command places you in <code>gbl-auto-diag</code> mode, where you must use the <code>schedule (gbl-auto-diag)</code> command to assign a schedule for collecting and sending diagnostic information. You can optionally use the <code>mail-to (gbl-auto-diag)</code> command to add additional E-mail recipients; the attachment is only encrypted for the E-mail to F5 Support. You can also use <code>additional-command</code> to add more <code>show</code> commands to the E-mail. To test the configuration, you can use the <code>auto-diagnostics test</code> command in <code>priv-exec</code> mode. The <code>show auto-diagnostics</code> command shows the current configuration for this utility, along with the status of the most-recent auto-diagnostics collection.</p> <p>In a redundant pair of ARX machines (see <code>redundancy</code>), both peers collect and send auto-diagnostics information through E-mail. All of the commands in <code>gbl</code> mode are shared between the peers, so only the active peer collects <code>gbl-mode</code> information (such as <code>show global-config</code> and <code>show namespace all</code>). Both peers collect and send commands related to <code>cfg</code> mode (such as <code>show running-config</code> and <code>show ron</code>). This also applies to any commands you add to the collection with <code>additional-command</code>; if the command relates to <code>gbl</code> mode, it is only included in collections from the currently-active peer. If the command relates to <code>cfg</code> mode, it is included in auto-diagnostic collections from both peers.</p> <p>To address an immediate issue, use the <code>collect</code> command to gather a larger amount of diagnostic information and possibly send it to F5 Support.</p>

**Guidelines: Show
Commands Included
in the Auto
Diagnostics
Collection**

The process always includes the following `show` commands in its E-mail attachment:

- `show clock`
- `show chassis`
- `show processors`
- `show processors usage`
- `show health`
- `show version`
- `show running-config`
- `show global-config`
- `show ron`
- `show namespace all`
- `show arp all`
- `show redundancy all`
- `show cores`
- `show statistics namespace ... fastpath all fastpath`
- `show policy details`
- `show cifs-service user-sessions all summary`
- `show statistics cifs authentication all`
- `show active-directory status detailed`
- `show statistics filer detailed`
- `show external-filer all`

Sample

```
bstnA(gbl)# auto-diagnostics  
bstnA(gbl-auto-diag)# ...
```

starts configuring auto diagnostics (and remote monitoring) for the “bstnA” switch.

Related Commands

```
schedule (gbl-auto-diag)  
mail-to (gbl-auto-diag)  
additional-command  
collect  
smtp  
auto-diagnostics test  
show auto-diagnostics
```

auto-diagnostics test

Purpose F5 Support can monitor your ARX from off site, watching for gradual loss of service or resource degradation. This is accomplished by the ARX gathering diagnostic information and sending it (encrypted) as an E-mail attachment to F5. After you set up the schedule for this [auto-diagnostics](#) data collection, you can use the `auto-diagnostics test` command to perform a test run.

Mode `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `auto-diagnostics test [local]`

local (optional) sends the E-mail to local recipients only, defined by the [mail-to \(gbl-auto-diag\)](#) command. This does *not* send any E-mail to F5.

Default(s) None.

Guidelines This command gathers auto diagnostics (as determined by the [auto-diagnostics](#) command and its sub-mode commands), compresses them into a Unix Tape Archive (tar) file, and sends the file through [smtp](#) as an E-mail attachment. This tests both the [auto-diagnostics](#) configuration and the [smtp](#) configuration.

By default, the E-mail goes to F5 Support and all configured [mail-to \(gbl-auto-diag\)](#) addresses. The E-mail attachment for F5 Support is encrypted, as it must travel outside your local network. The E-mail attachment is unencrypted for each of the local [mail-to \(gbl-auto-diag\)](#) addresses, for convenience. You can use the `local` option to send the test message only to the local addresses.

The E-mail messages from this test have a different “subject” line than standard messages from scheduled runs: the subject line begins with “Test:”.

Sample `bstnA# auto-diagnostics test local`
collects and sends auto diagnostics, unencrypted, to the local E-mail addresses set by the [mail-to \(gbl-auto-diag\)](#) command.

Related Commands [auto-diagnostics](#)
[mail-to \(gbl-auto-diag\)](#)
[smtp](#)

clear health

Purpose Certain SNMP traps raise persistent alarms on the system. For each “raise” trap, there is a corresponding “clear” trap that clears the alarm condition. You can use the `clear health` command to manually clear a raised alarm condition.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear health trap`

trap (1-64 characters) identifies the trap(s) to be cleared. Use `show health` to see a list of traps with open alarm conditions. Use the **Event** name from the output of `show health`.

Default(s) None

Guidelines The `show health` command shows all currently-raised traps on the system. For cases where a raised trap is unlikely to every be cleared by its corresponding “clear” trap, you can use this command to manually clear the trap. This clears all instances of the given trap. Then the alarm condition no longer appears in the `show health` output.

Sample `bstnA# clear health diskFail`
clears all diskFail traps.

Related Commands `show health`

collect

Purpose	Some machine problems require more diagnosis than is possible on-site. Use the <code>collect</code> command to collect diagnostic data on the switch and either upload it or store it locally.
Mode	<code>priv-exec</code>
Security Role(s)	<code>network-technician</code> , <code>network-engineer</code> , <code>storage-engineer</code> , or <code>crypto-officer</code>
Syntax: Uploading to an FTP Site	<code>collect {all diag-info config cores logs stats-logs reports state capture} ftp://[user:password@]server/file.tgz [async]</code>

`all | diag-info | config | cores | logs | stats-logs | report | state | capture` chooses the type of diagnostics to be collected:

all collects all diagnostic files on the switch.

diag-info collects all diagnostic files on the switch except reports, which can be excessively large.

config collects the configuration database, database logs, and the output from `show running-config` and `show global-config`.

cores gathers any core-dump files on the system, along with all shared-object libraries used by the system.

logs assembles the syslog, the `procdat` log (process data; a more-detailed log file for diagnosis by engineers), upgrade and installation logs, disk-usage logs, Kerberos state files, and logs from the system's service manager. For options to collect logs from specific times, see the documentation for [collect logs](#).

stats-logs selects all stats-log files, `.csv` files with performance data relevant to the ARX, its filers and servers, and other external devices. You can use the `show stats-logs` command to list all of the stats-log files currently available.

reports chooses all reports.

state collects individual log files from every processor in the switch, three system log files (`syslog`, `procdat`, and `traplog`), a chronological list of all CLI commands used since the switch booted, the latest of each of the stats-log files, and the output from a series of useful `SHOW` commands.

capture selects only the packet-capture files, if there are any. These files show the flow of IP traffic through the ARX during a [capture session](#). You can use `show capture` to list all of the capture files currently available.

`ftp://[user[:password]@] server/file.tgz` (1-1024 characters) is the destination URL:

`user[:password]@` (optional) is the username and password (for example, "random:pw@"). If you omit the password, the CLI prompts you for one.

`server` is the machine name (for example, "mymachine.myco.com").

`file.tgz` is the desired path name for the file. Lead with an extra slash (/) if the path is absolute: for example, "...myserver//var/log/acopiaDiags.tgz" specifies `/var/log/acopiaDiags.tgz` on "myserver." Use only a single slash if the path is local to the *user*'s home directory.

Syntax: Uploading to an FTP Site (Cont.) `async` (optional) makes this command return immediately, rather than waiting for the collection process to finish. The CLI generates a report that you can use to chart the collection process; the report name appears after the process starts.

Syntax: Secure Upload through SCP `collect {all | diag-info | ... | capture}`
`scp://[user@]server:file.tgz [accept-host-key] [async]`

`{all | ... | capture}` define the collection process, as explained above.

`scp://[user@]server:file.tgz` (1-1024 characters) is the URL for the destination file:

`user@` (optional if someone created an [ip scp-user](#)) is the username to present to the other end of the SCP connection. This user must be valid at the remote host. If you omit this and an [ip scp-user](#) is defined, it defaults to the username set by that command.

`server:` is the IP address or hostname for the SCP host. End with a colon (:).

`file.tgz` is the destination-file path. Lead with a slash (“/”) if the path is absolute (for example, “`scp://root@10.1.1.5:/var/diags/arx.tgz`”). Use no slash if the path is local to the home directory for `user` (for example, “`scp://root@10.1.1.5:diags.tgz`”).

`accept-host-key` (optional) indicates that if the other end of the connection has an unknown SSH host key (that is, if it is new, or if its key has changed since the last time the host was contacted), the ARX should accept the new host key and continue with the upload. Otherwise, the ARX stops the upload if the host presents an unknown key.

`async` (optional) was explained above.

Syntax: Sending to an ARX Volume `collect {all | diag-info | ... | capture}`
`{nfs|cifs} namespace vol file.tgz [async]`

`{all | ... | capture}` are explained above.

`nfs | cifs` is a required choice. This chooses the protocol for the file transfer.

`namespace` (1-30 characters) identifies the namespace to hold the collect file.

`path` (1-1024 characters) is the volume name.

`file.tgz` is the path to the collect file, starting at the root of the volume.

`async` (optional) was explained above.

Syntax: Uploading to a TFTP Server `collect {all | diag-info | ... | capture} tftp://server/file.tgz`
`[async]`

`{all | ... | capture}` are explained above.

`tftp://server/file.tgz` (1-1024 characters) is the URL for the collect file:

`server` is the machine name (for example, “`mymachine.myco.com`”).

`file.tgz` is the desired path name for the file. Lead with an extra slash (/) if the path is absolute: for example, “`...myserver//var/log/acopiaDiags.tgz`” specifies `/var/log/acopiaDiags.tgz` on “`myserver`.” Use only one slash if the path is local to the server’s “`tftpboot`” directory. This conforms with the specification for FTP URLs in RFC 1738.

`async` (optional) was explained above.

Syntax: Sending to an E-mail Address `collect {all | diag-info | ... | capture} smtp://[e-mail-address]/file.tgz [async]`

`{all | ... | capture}` are explained above.

`smtp://[e-mail-address]/file.tgz` (1-1024 characters) is an E-mail destination for the collect file:

`smtp://` declares that the destination is an E-mail address.

e-mail-address (optional) is the recipient of the E-mail in *username@host* format (for example, “jsmith@myco.com”). If you omit this, the CLI uses the default address set by the `cfg-smtp to` command.

file.tgz is the name of the copy. This is sent as an attachment to the outbound E-mail message. This is not a path, so do not use slashes (/). You must use a .tgz extension. For example, “...acopiaDiags.tgz” is a valid file name.

`async` (optional) was explained above.

Syntax: Collecting Locally `collect {all | diag-info | ... | capture} local-file.tgz [async]`

`{all | ... | capture}` are described above.

local-file.tgz (1-1024 characters) saves the file locally, to the diag-info directory. To preserve disk space, you can only save one diag-info file at a time. You must use a .tgz extension.

`async` (optional) was explained above.

Default(s) (FTP only) If you omit the *user:password* from the FTP URL, the CLI uses the username and password set by the `ip ftp-user` command.

Guidelines This file contains multiple log files and possibly core files, so it can be very large. If you upload it, choose a host with ample disk space. If you send the message through SMTP, configure the local E-mail server (chosen with the `mail-server` command) and the recipient E-mail server to allow very large E-mail messages. (The E-mail server at F5 Support allows for large messages.)

For SCP uploads, the CLI prompts for a password; enter the password for the *user* that you identified in the URL. The CLI also prompts for a password for FTP uploads where you do not supply one in the command.

The CLI prompts for confirmation before collecting the diagnostics. Answer **yes** to continue. The collection process can be time-consuming; prompts appear to show the progress of the operation as it occurs.

You must configure SMTP on the ARX before you use the “smtp://” syntax for E-mail. Start with the `smtp` command in `cfg` mode.

For saves to the local disk, you can only save one “collect” file at a time. If one already exists, the CLI prompts for permission to overwrite the previously-collected file. Use `show diag-info` to show that the file was created on disk.

Samples bstnA# `collect diag-info ftp://jpublic@arxftp.f5.com/10-24-03.tgz`
Password: `jpassword`

Collect diagnostic information? [yes/no] `yes`
sends all diagnostic information to the FTP server at arxftp.f5.com.

bstnA# `collect diag-info cifs medarcv /rcrds admin/collect.tgz`

Collect diagnostic information? [yes/no] `yes`
sends all diagnostic information to a CIFS volume on the ARX,
“medarcv~/rcrds.”

bstnA# `collect config ftp://arxftp.f5.com/10-24-03.tgz`

Collect diagnostic information? [yes/no] `yes`
sends only config information. This uses the FTP credentials established by the `ip ftp-user` command.

bstnA# `collect diag-info investigate.tgz`

Only one copy of diagnostic information may be stored on the switch at one time. This automatically removes any saved diagnostic information.

Are you sure? [yes/no] `yes`
collects all diagnostic information in a local file.

prtlnA# `collect logs smtp://logsAndReports.tgz`

Collect diagnostic information? [yes/no] `yes`
collects all logs and sends them in an E-mail attachment.

Related Commands `collect logs`
`copy ftp`
`copy scp`
`copy smtp`
`copy {nfs|cifs}`
`copy tftp`
`ip ftp-user`
`ip scp-user`
`smtp`
`show diag-info`

collect logs

Purpose You can collect all log files on the system at once, or you can focus on the logs from a specific time. This is an extension of the [collect](#) command that applies to log files only.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `collect logs [start-time start [utc]] [end-time end [utc]] destination [async]`

start-time start [utc] (optional) sets a starting time for collected logs. If you omit this, the CLI collects all of its logs up to the **end-time**.

start is a time stamp in one of two formats:

- *mm/dd/yyyy:HH:MM:SS* is designed for manual entry of a date and time.
- *yyyy-mm-ddTHH:MM:SS* is designed for a copy-and-paste of a time stamp from a log file. Time stamps from log files are in UTC instead of local time.

utc (optional) declares that the start is in UTC instead of local time. This is typically used for time stamps copied from a log file (the second format from above).

end-time end [utc] (optional) sets an end time for collected logs. If you omit this, the CLI collects all of its logs after the **start-time**. The details of this time stamp are otherwise the same as above.

destination is a local-file name, an ARX volume, or a URL. The URL can use FTP, SCP, TFTP, or SMTP. The documentation for the [collect](#) command describes the exact syntax.

async (optional) makes this command return immediately, rather than waiting for the collection process to finish. The CLI generates a report that you can use to chart the collection process; the report name appears after the process starts.

Default(s) If you omit the optional flags, the CLI collects all logs.

Guidelines This is an alternative syntax for the [collect](#) command. It is useful for collecting logs from a specific time frame; this can reduce the size of the collection as well as focus a diagnosis.

Samples bstnA# collect logs start-time 06/05/2007:12:00:00 end-time
06/05/2007:13:00:00 ftp://jpublic@arxftp.f5.com/1hr
Password: jpassword

Collect diagnostic information? [yes/no] yes

collects logs from noon until 1PM on June 5, 2007. It then sends the collected logs to an FTP site.

prtlnA# collect logs start-time 2007-01-07T05:00:34 utc sinceBoot.tgz

Only one copy of diagnostic information may be stored on the switch at one time. This automatically removes any saved diagnostic information.

Are you sure? [yes/no] yes

collects all logs since the given time (in UTC format). All of the logs are placed in a local file named "sinceBoot.tgz."

Related Commands [collect](#)

expect monitor

Purpose You can use the `expect monitor` command to repeat a `show` command at regular intervals.

Mode `priv-exec`

Security Role(s) `crypto-officer`, `storage-engineer`, `network-engineer`, or `network-technician`

Syntax `expect monitor seconds "show-command" ["search-string"] [timeout timeout-seconds]`

seconds is the number of seconds to wait between each invocation of the command.

"show-command" is a valid CLI show command, surrounded by quotation marks ("""). Use any of the `show` commands documented in this manual.

"search-string" (optional) also requires quotes. If you use this, the command stops repeating as soon as the *search-string* appears in the output. Otherwise, the command repeats until you use `<Ctrl-C>` to stop it.

timeout-seconds (optional, 1-2096) sets a time limit on this monitor process. The show commands stop repeating when this time expires. You can also use `<Ctrl-C>` to stop the process at any time.

Default(s) *timeout-seconds* - 21,600 (6 hours)

Guidelines You can use this command to watch the progress of a configuration change from the CLI. For example, this command can repeat the `show redundancy` command after you `enable (cfg-redundancy)` redundancy for a pair of ARXes, to monitor their initial rendezvous.

You cannot issue other CLI commands in this session while the `expect monitor` command is running. Use `<Ctrl-C>` to stop the repetition at any time.

To run a full CLI script, copy the script onto the ARX (using `copy ftp`, `copy scp`, `copy {nfs|cifs}`, or `copy tftp`), and then use `run` to invoke it. To perform any command in the future (possibly on a schedule), use the `at` command.

Samples `bstnA# expect monitor 5 "show namespace wamed"`
repeats the `show namespace wamed` command every 5 seconds, until you use `<Ctrl-C>` to stop it.

`bstnA# expect monitor 10 "show namespace medarcv" "/rcrds"`
repeats the `show namespace medarcv` command every 10 seconds until `"/rcrds"` appears in the output.

Related Commands `at`
`run`

logging destination

Purpose	Use the <code>logging destination</code> command to define an external syslog server as an external logging destination. Use the <code>no</code> form of the command to remove a syslog server.
Mode	cfg
Security Role(s)	network-engineer or crypto-officer
Syntax	<code>logging destination server-name [udp tcp] [port port]</code> <code>no logging destination server-name</code> <i>server-name</i> (1-80) is the IP address or hostname of the external syslog server. <code>udp tcp</code> (optional) is the transport protocol over which to send the syslog messages. <code>port port</code> (optional, 1-65,535) is the UDP or TCP port number where the external server is listening.
Default(s)	<code>udp</code> <code>port 514</code>
Guidelines	The external server receives log messages as they are generated and appends them to its local syslog file. Use the show logging destination command to list all configured external syslog servers.
Samples	<code>bstnA(cfg)# logging destination 10.1.1.76 tcp</code> sends syslog messages over TCP to an external syslog daemon at 10.1.1.76. <code>bstnA(cfg)# no logging destination 172.16.44.7</code> stops sending syslog messages to 172.16.44.7.
Related Commands	show logging destination

logging level

Purpose Each group of log messages, known as a log component, has a separately-tunable *logging level*. Critical level is the most terse, displaying critical log messages only; debug level is the most verbose, displaying all log messages from critical down to debug. The messages appear in the syslog file. Use the `logging level` command to set a logging level.

Use the `no` form of this command to revert a logging level back to the default.

Mode `cfg`

Security Role(s) `network-engineer` or `crypto-officer`

Syntax `logging level component {critical | error | warning | notice | info | debug | disable}`
`logging level all {critical | error | warning | notice | info | debug | disable}`
`no logging level {component | all}`

component (up to 255 characters) is the component to tune. See [Log Components](#), on page 38-3 for a complete list of components.

`all` selects all components.

`critical | error | warning | notice | info | debug | disable` is a required choice. This is the logging level you choose for the component. The `disable` option stops all logging from the chosen *component*.

Default(s) `info`

Guidelines Use [show logging levels](#) to verify the log-level settings for each component. From any mode, use [show logs syslog](#) or `grep pattern logs syslog` to view the log messages in the syslog file. See the manual, *ARX Log Catalog*, for a full list of log messages.

This command applies to components on the ACM. To enable log messages for the NSM, use [logging fastpath processor](#) and [logging fastpath component](#).

Samples `bstnA(cfg)# logging level NSCKRPT debug`
 sets the logging level to debug (as verbose as possible) for NSCKRPT messages.

`bstnA(cfg)# logging level all error`
 sets the logging level to error (fairly terse) for all messages.

`bstnA(cfg)# no logging level all`
 sets the logging level to the default for all messages.

`bstnA(cfg)# logging level RON disable`
 disables logging for the RON component.

`bstnA(cfg)# no logging level POLICY_ACTION`
 sets the logging level to the default for POLICY_ACTION messages.

Related Commands [show logging levels](#)
 [show logs](#)
 [grep](#)
 [logging fastpath processor](#)
 [logging fastpath component](#)

mail-to (gbl-auto-diag)

Purpose The auto-diagnostics utility gathers performance data and sends it to F5 Support. It sends the data as an E-mail attachment. You can use the **mail-to** command to add an additional destination address for these E-mails.

Use the **no mail-to** command to remove an E-mail recipient.

Mode gbl-auto-diag

Security Role(s) storage-engineer or crypto-officer

Syntax **mail-to** *recipient*
no mail-to *recipient*

recipient (1-128 characters) is one E-mail recipient (for example, “juser@nemed.com”).

Default None

Guidelines This sets a destination for auto-diagnostics E-mail messages. This E-mail recipient receives a copy of every auto-diagnostics collection that the ARX assembles. This is in addition to the copy sent to F5 Support. The attachment delivered to F5 Support is encrypted, but the attachment sent to this E-mail recipient is not.

The maximum number of E-mail recipients is limited by the total bytes required to store them. If they are concatenated into a single string, separated with commas, the total string length cannot exceed 1024 bytes.

You cannot remove F5 Support as an E-mail recipient.

Samples `bstnA(gbl-auto-diag)# mail-to juser@wwmed.com`
sets up one E-mail recipient for the “bstnA” switch. Whenever the bstnA switch sends out auto-diagnostics to F5 Support, it also sends an unencrypted copy of the diagnostics to juser@wwmed.com.

`prt1ndA(gbl-auto-diag)# no mail-to ex@nemed.com`
removes an E-mail recipient.

Related Commands [auto-diagnostics](#)

management source

Purpose	Use the <code>management source</code> command to set a source address for sending syslog messages. Use the <code>no</code> form to remove the management-source configuration.
Mode	cfg
Security Role(s)	network-engineer or crypto-officer
Syntax	<code>management source {mgmt vlan <i>vlan-id</i>}</code> <code>no management source</code> <code>mgmt</code> is the switch's out-of-band management interface, the default. You specify the out-of-band management IP address at switch boot-up. <code>vlan</code> specifies to use a configured VLAN. <code>vlan-id</code> (1-4096) identifies the VLAN to use as the source. Use the show vlan summary command for a list of all configured VLANs.
Default(s)	<code>mgmt</code> on platforms that support this command <code>vlan 1</code> on platforms that do not support this command.
Platforms	any <i>except</i> ARX-VE
Guidelines	Use logging destination to send syslog messages to an external syslog server. This command sets the source address for those log messages. If you remove a VLAN interface that is configured as the management source, the syslog does not function properly. You must configure another source (mgmt or VLAN). The in-band management address for VLAN 1 (the default VLAN) is always the management source for an ARX-VE. The ARX-VE has no out-of-band management interface. Use the show logging destination command to view the current management source.
Sample	<pre>bstnA(cfg)# management source vlan 9</pre> configures VLAN 9 as the management source for sending syslog traffic and SNMP traps.
Related Commands	logging destination show logging destination show vlan summary

moving-average

Purpose **** This is a beta-level command. It does not appear in the CLI unless you use the [terminal beta](#) command to unlock all beta-level commands. ****

The ARX records the round-trip times between itself and external devices, such as CIFS clients and back-end filers. The *stats-monitor* process keeps moving averages of these round-trip times and other statistics, and records them in .csv files in the stats-log directory. The stats monitor also can log *notification* messages if the number of errors and/or response time from an external device increases dramatically. The stats monitor only logs a notification if the device has these increases multiple times in a row. Use the **moving-average** command to define the percentage of increase required, and the number of times that the errors or response times must increase that much to merit a notification.

Use **no moving-average** to return to the default thresholds.

Mode gbl-stmon-nfy

Security Role(s) storage-engineer or crypto-officer

Syntax **moving-average** {*response-time* | *errors*} **threshold** *pct-threshold*
moving-average {*response-time* | *errors*} **interval** *num-samples*

no moving-average {*response-time* | *errors*} **threshold**

no moving-average {*response-time* | *errors*} **interval**

response-time | **errors** is a required choice. This determines the type of threshold or interval you are setting, response times or errors.

threshold *pct-threshold* (optional, 1-65,535) is the percentage above the moving average that could trigger an alarm. For example, if you set **moving-average response-time threshold 200**, the stats monitor may trigger a notification if a device's response time is 200% above (or, 3 times) its current moving average. As another example, if you set **moving-average errors threshold 150**, stats monitor may trigger a notification if the device's number of errors is 150% above its current average. The stats monitor process only triggers the notification if this occurs for some number of samples, as set by the **interval** option.

interval *num-samples* (optional, 1-65,535) is the number of high samples in a row that are required to trigger a notification. If this many samples in a row are at least *pct-threshold* above the current average, the stats-monitor process logs a notification.

Default(s) either **threshold** - 100%

either **interval** - 6

Guidelines This is a beta-level command. Use the [terminal beta](#) command to unlock all beta-level commands, including this one.

The defaults are sufficient for most sites. Use this command only on the advice of F5 Support.

This command changes the moving-average thresholds for one set of filers or ARX front-end services, chosen when you use the [notify](#) command to enter the mode.

The *moving average* is the average for a number (for example, 8) of the most-recent samples. The 8th time the software calculates a moving average, it takes the average of samples 1 to 8; the 9th time it runs, it averages samples 2 to 9; the 10th time, it takes the average of samples 3 to 10; and so on.

If a group of samples deviates from the current moving average, the stats monitor generates a notification. Use this command, **moving-average**, to decide how many samples in a row it takes to log the notification, and to decide how far over the current average a sample must be to qualify.

These notifications are recorded in the syslog; you can use [show logs syslog](#) to view them along with all other syslog messages. Look for the log component named “SMON_ANALYSIS,” or use [grep](#) to search for it. To create an additional SNMP trap for each notification, use the [trap](#) command.

The stats monitor collects data for a long period of time, called a *moving-average window*, before it starts using the moving average for notifications. This window is calculated from the **moving average** and **sampling interval** commands: it is $8 * \text{moving-average interval} * \text{sampling interval}$. By default, that is $8 * 6 * 5$ minutes, or four hours. The moving-average window restarts if you use the **sampling interval** command to change the sampling interval.

Samples `bstnA(gbl-stmon-nfy)# moving-average response-time threshold 10`
`bstnA(gbl-stmon-nfy)# moving-average response-time interval 3`
sets the following tolerances for response times: if a device’s response time is **10%** (or more) slower than its current average for **3** samples in a row, stats monitor logs a notification message. It also sends an SNMP trap if [trap](#) is enabled.

`bstnA(gbl-stmon-nfy)# moving-average errors threshold 5`
`bstnA(gbl-stmon-nfy)# moving-average errors interval 3`
sets the following tolerances for errors: if a device returns **5%** (or more) errors than its current average for **3** samples in a row, stats monitor logs a notification message. As above, stats monitor also sends an SNMP trap if [trap](#) is enabled.

Related Commands [notify](#)
[trap](#)

notify

Purpose **** This is a beta-level command. It does not appear in the CLI unless you use the [terminal beta](#) command to unlock all beta-level commands. ****

The ARX records the round-trip times between itself and external devices, such as CIFS clients and back-end filers. You can use the `notify` command to trigger analysis for one group of external devices: CIFS-service clients, NFS-service clients, CIFS filers, and or NFS filers. Whenever an issue is discovered for one of the analyzed device groups, the stats-monitor process logs a *notification* in the syslog. Optionally, the stats monitor can also send an SNMP trap. This command also brings you into a submode, where you can alter the notification settings for the chosen group of devices.

You can use the negative form of the command, `no notify`, to deactivate this stats-monitor process for front-end or back-end services.

Mode gbl-stmon

Security Role(s) storage-engineer or crypto-officer

Syntax `notify {cifs-service | nfs-service}`
`notify filer-share {cifs | nfs}`

`no notify {cifs-service | nfs-service}`
`no notify filer-share {cifs | nfs}`

`cifs-service` | `nfs-service` is a required choice. The `nfs-service` option starts analyzing all `nfs` front-end services, and the `cifs-service` option starts analyzing all `cifs` front-end services.

`cifs` | `nfs` is a required choice if you choose to monitor filer shares. This chooses between analyzing CIFS or NFS on back-end filers.

Default(s) `no notify cifs-service`
`no notify nfs-service`
`no notify filer-share cifs`
`no notify filer-share nfs`

Guidelines This is a beta-level command. Use the [terminal beta](#) command to unlock all beta-level commands, including this one.

The `notify` command places you in `gbl-stmon-nfy` mode, where you can use other CLI commands to edit the notifications for the set of devices you have chosen. The notifications only occur when some number of samples deviates from the moving average by some percentage; for example, a notification occurs when 6 samples from a particular CIFS service have twice as many `NetworkErrors` as the moving average, or when 6 samples from a particular back-end NFS export have progressively-higher round-trip times for `GETATTR` requests. You can use the [moving-average](#) command to reset the number of samples to trigger a notification, and/or to change the threshold for each sample to qualify as “too high.” By default, a notification goes to the syslog only; the [trap](#) command enables SNMP traps in addition to those syslog messages.

The stats monitor records its notifications in the syslog; you can use [show logs syslog](#) to view them along with all other syslog messages. Look for the log component named “`SMON_ANALYSIS`,” or use [grep](#) to search for it. To create an additional SNMP trap for each notification, use the [trap](#) command.

Sample

```
bstnA(gbl-stmon)# notify cifs-service
bstnA(gbl-stmon-nfy)#
    enables analysis of all front-end cifs services.
```

Related Commands [stats-monitor](#)
[moving-average](#)
[trap](#)
[show health](#)

sampling interval

Purpose *** *This is a beta-level command. It does not appear in the CLI unless you use the [terminal beta](#) command to unlock all beta-level commands.* ***

The ARX records the round-trip times between itself and external devices, such as CIFS clients and back-end filers. The stats-monitor process keeps running averages of these round-trip times and other statistics, and records them in .csv files in the stats-log directory. You can use the **sampling interval** command to determine the interval at which these samples are recorded.

Use **no sampling interval** to return to the default interval.

Mode gbl-stmon

Security Role(s) storage-engineer or crypto-officer

Syntax **sampling interval *seconds***
no sampling interval

seconds (30-86,400) is the number of seconds between each sample. 86,400 seconds is one day.

Default(s) 300 (seconds, or 5 minutes)

Guidelines This is a beta-level command. Use the [terminal beta](#) command to unlock all beta-level commands, including this one.

The default is sufficient for most sites. Use this command only on the advice of F5 Support.

If you select a sampling interval that is shorter than the default, the stats-monitor process writes .csv files more frequently. These raw .csv files are kept (together with all other log files) on a separate disk partition from configuration files and other important data. Each hour, the stats-monitor also creates an hourly file with the hour's first set of samples; this is a summary of the data in the raw file. Use [show stats-logs](#) to see a list of these .csv files, or [show stats-logs file-name](#) to view the contents of one of them. The stats-monitor files are not permitted to consume more than 50% of the log partition. If the .csv files approach their size limit, the oldest raw-data files are removed and the hourly-summary files remain.

This command restarts the calculation of all moving averages. After you invoke this command, stats monitor must run for the full *moving-average window* before it can log any more notifications (or, possibly, send any more traps). This window is calculated from the **sampling interval** command as well as the [moving-average](#) command: it is $8 * \text{moving-average interval} * \text{sampling interval}$. By default, that is $8 * 6 * 5$ minutes, or four hours.

Sample bstnA(gbl-stmon)# **sampling interval 60**
reduces the sampling interval (and raises the sampling frequency) to once every minute.

Related Commands [stats-monitor](#)
[show stats-logs](#)
[moving-average](#)

schedule (gbl-auto-diag)

Purpose The auto-diagnostics utility gathers data about the ARX, encrypts it, and sends it in an E-mail message to F5 Support. Use this **schedule** command to assign a schedule for this operation.

Use **no schedule** to remove the auto-diag schedule, thereby disabling auto diagnostics.

Mode gbl-auto-diag

Security Role(s) storage-engineer or crypto-officer

Syntax **schedule** *name*
no schedule

name (1-64 characters) identifies the schedule for auto diagnostics. Use [show schedule](#) for a list of configured schedules. Choose a schedule that has a frequency measured in days, weeks, or a longer time measure; for example, every day, every 3 days, every 1 week, or every 2 months. This command does not accept a schedule with a higher frequency, such as every 12 hours.

Default(s) None.

Guidelines The auto diagnostics utility gathers performance information about your system and regularly sends it to F5 Support. This command sets the schedule for sending this information. The auto diagnostics utility requires a schedule in order to run automatically.

To create a schedule, use the gbl-mode [schedule](#) command. The schedule cannot run more frequently than once per day; you can define this with the [every](#) command.

Sample `minturnA(gbl-auto-diag)# schedule every2am`
uses a schedule named “every2am” for auto-diagnostic collection on “minturnA.”

Related Commands [auto-diagnostics](#)
[schedule](#)
[show schedule](#)

show auto-diagnostics

Purpose F5 Support can monitor your ARX from off site, watching for gradual loss of service or resource degradation. This is accomplished by the ARX gathering diagnostic information and sending it (encrypted) as an E-mail attachment to F5. After you set up the schedule for this [auto-diagnostics](#) data collection, you can use the `show auto-diagnostics` command to show the auto-diagnostics configuration along with the status of the latest auto-diagnostics run.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show auto-diagnostics`

Guidelines The output contains several tables of configuration information, followed by a table showing the status of the last auto-diagnostics run.

Schedule is the schedule's configured name, chosen with the [schedule \(gbl-auto-diag\)](#) command. The fields in this table show the configuration of the schedule.

Description only appears if set by the `gbl-schedule description (gbl-schedule)` command.

Start Time can be reset by the `gbl-schedule start` command. This is the date and time of day used for all time-based calculations: for example, if a schedule runs every Saturday, this determines the time of day on Saturdays when the schedule fires.

Stop Time only appears if set by the `gbl-schedule stop` command. This is the expiration time for the schedule, after which the schedule never fires.

Interval is set by the `gbl-schedule every` command. This is the time between scheduled runs.

Duration appears only if set by the `gbl-schedule duration` command. This is not applicable to auto-diagnostics.

Status is "Paused" (the schedule is between run times), "Running," or "Waiting for start time" (the schedule has never been invoked).

Previous is a sub-table showing the **Run time** (when the run started) and **End time** of the most-recent run.

Current appears if the rule is currently running. This has the same fields as the **Previous** table, **Run time** and **End time**.

Next shows when the schedule's next run will begin. It also has the **Run time** and **End time** fields.

Mail-to is a list of local E-mail addresses, added with the [mail-to \(gbl-auto-diag\)](#) command. Every time the above schedule fires, the system sends a tar file with auto-diagnostic output to each of these addresses. It also sends an encrypted version of the same tar file to F5 Support.

- Guidelines (Cont.)** Additional commands are extra CLI-show commands that are collected along with the default auto-diagnostics. You can add or remove these with the [no] [additional-command](#) command.
- Status describes the most-recent auto-diagnostics collection and delivery operation since the last reboot. The following fields appear only if an auto-diagnostics collection has occurred:
- Last time executed is the most-recent time that the schedule fired and the collection process started.
 - Status of last execution is either “Success” or “Failure” with a report name in square brackets. You can use [show reports report-name](#) to read the report and find the specific failure.
 - Date last sent is a time stamp for the most-recent E-mail delivery.
 - Number of times sent since last reboot shows how many times the system has collected and delivered auto-diagnostics data since the last ARX reboot.

Sample `bstnA(cfg)# show auto-diagnostics`
shows the auto-diagnostics configuration and status for the “bstnA” switch. See [Figure 38.1](#) for sample output.

Related Commands [auto-diagnostics](#)

Figure 38.1 Sample Output: show auto-diagnostics

Number of times sent since last reboot: 2
```

show documentation

Purpose Many syslog and CLI-response messages have further documentation to help with problem assessment and diagnosis. Use the `show documentation` command to display the documentation for a given message.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show documentation msg-catalog-id`

msg-catalog-id (1-255 characters) identifies the message. Every message-catalog message has an uppercase ID that appears with it in the syslog and in the CLI.

Guidelines The output shows the documentation for a particular message-catalog message. The CLI, the syslog, and most processes share a common message catalog. The full message catalog is documented in an alphabetical reference, the *ARX Log Catalog*.

Sample `bstnA(cfg)# show documentation SQM_CANNOT_BE_PROMOTED_GRACE_PERIOD`
shows the documentation for one message ID. See [Figure 38.2](#) for sample output.

Related Commands [show logs](#) `syslog`

Figure 38.2 Sample Output: show documentation

```
bstnA(cfg)# show documentation SQM_CANNOT_BE_PROMOTED_GRACE_PERIOD
```

```
SQM_CANNOT_BE_PROMOTED_GRACE_PERIOD documentation:
```

```
In order to force a seniority promotion, the remote peer switch must be
offline and the local switch must be stalled waiting for it to come online.
This condition is indicated by the presence of the "Peer has more recent
configuration..." (SQM_PTN_IN_TIME_STALL) message in the 'show redundancy
history' output. Unless the switch has been in this stalled state for at
least five minutes, it cannot be promoted.
```

show health

- Purpose** Certain SNMP traps raise persistent alarms on the system. For each “raise” trap, there is a corresponding “clear” trap that clears the alarm condition. Use the `show health` command to see all SNMP-related alarms that have been raised but not cleared.
- Mode** (any)
- Security Role(s)** crypto-officer, storage-engineer, network-engineer, network-technician, or operator
- Syntax** `show health`
- Guidelines** This shows a table with one row per active alarm. Each row has the following columns:
- Date** is the date and time when the event occurred.
 - ID** is the last three digits in the trap’s OID.
 - Event** is the name of the trap.
 - Description** explains the alarm condition.
- Refer to the [ARX SNMP Reference](#) for a full list of all traps, along with explanations for each trap and procedures to address the issue.
- To manually clear a raised trap, you can use the `clear health` command.
- Follow the Guidelines for the command, [snmp-server traps](#), to set up a remote host to receive SNMP traps. For an overall view of the system hardware, use `show chassis`.
- Samples**
- ```
prtlnA(cfg)# show health
```
- shows any raised alarms on the “prtlnA” chassis. See [Figure 38.3 on page 38-40](#) for sample output.
- ```
bstnA> show health
```
- shows any raised alarms on the “bstnA” chassis. See [Figure 38.4 on page 38-41](#) for sample output.

show health time-skew

Purpose Several ARX applications require clock synchronization between the ARX and its network peers. These applications include Kerberos, which frequently uses time stamps, and the policy engine, which often places files based on their last-modified times. Use the `show health time-skew` command to see the clock differences between the ARX and other stations with which it communicates.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show health time-skew [timeout seconds]`

timeout seconds (optional, 1-3600) is the maximum number of seconds to wait for each server response. The default timeout is 3 seconds. The ARX makes two or more attempts in some cases, and this timeout applies to each attempt. Also, the timeout applies to each individual server; the overall time for all servers to respond may be significantly longer. You can use <Ctrl-C> to stop the command at any time.

Guidelines We strongly recommend using NTP to keep the ARX clock synchronized with other system clocks on the network. Use the [ntp server](#) command to connect the current switch to one or more NTP servers.

The output shows a table with one row per network peer. Each row has the following columns:

IP Address identifies the network device.

Role shows the relationship of this device to the ARX. Possible values here are “External Filer” or “Domain Controller.” Use the [show external-filer](#) command for a full list of external filers used by this ARX. Use the [show active-directory](#) command for a full list of DCs and a general understanding of how the ARX is using them.

Observed Time Skew ... shows a time value in *HH:MM:SS* format, followed by “ahead,” “behind,” or (for a time value of “00:00:00”) nothing.

Sample `bstnA> show health time-skew timeout 30`
shows the time skews between the “bstnA” chassis and its network peers. See [Figure 38.5 on page 38-42](#) for sample output.

Related Commands [ntp server](#)
[show external-filer](#)

show id-mappings

Purpose Syslog messages use numeric IDs to identify namespaces, volumes, shares, and file-history archives. Use the `show id-mappings` command to map these IDs to the names used in the CLI.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show id-mappings`

Guidelines The output shows four tables:

Namespace lists all namespaces on the switch, one per row. The **ID** column contains the numeric ID.

Volume lists all volumes on the switch, one per row. The **Namespace** column shows the volume's namespace, and the **ID** column contains the volume's numeric ID.

Share lists all shares on the switch, one per row. The **Volume** and **Namespace** columns show the share's context, and the **ID** column contains the share's numeric ID. Contact F5 Support if "Not Found" appears at the end of any of these rows; this indicates an issue in the configuration database.

Archive Name is a table of file-history archives on the ARX. A *file-history archive* is a repository for a managed volume's file-location records. You can use the [file-history archive](#) command to create one. The **ID** column in this table contains the archive's numeric ID.

Sample `bstnA(cfg)# show id-mappings`
shows the ID mappings on the current switch. See [Figure 38.6](#) for sample output.

Related Commands [show logs](#) [syslog](#)

show logging destination

Purpose Use the `show logging destination` command to view a list of configured external syslog servers.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show logging destination`

Guidelines The output contains the Source Interface used for communicating with the syslog servers, followed by a list of syslog servers.

Use the [logging destination](#) command to define a syslog server.

Use the [management source](#) command to define a source address for sending syslog messages and traps.

Sample `bstnA# show logging destination`

```
Source Interface:  mgmt (10.1.1.7)
```

```
External Syslog Destination(s)
-----
172.16.202.8
```

Related Commands [logging destination](#)
[management source](#)

show logging levels

Purpose Log messages are divided into groups based on the system components that generate them. You can set a logging level for each component, from critical (terse; shows only the most-urgent messages) to debug (verbose). Use the `show logging levels` command to list all of the log components and the current logging level for each.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show logging levels [component]`

component (optional) specifies that you only want the logging level for the given component.

Guidelines The log components are listed in an earlier section; see [Log Components](#), on page 38-3. This command shows the logging levels in a graph: for each log component, an X appears in the column of its logging level. Use the [logging level](#) command to change any or all component-logging levels.

Samples `bstnA(cfg)# show logging levels`
shows the logging levels for all components. See [Figure 38.7](#), below.

`bstnA(cfg)# show logging levels POLICY`
shows the logging levels for one component, POLICY. See [Figure 38.7](#), below.

Related Commands [logging level](#)

show stats-monitor

Purpose	The stats-monitor process keeps round-trip-time (RTT) and error statistics for communication between the ARX and external devices, as well as internal performance statistics. It also analyzes this data, watches for sudden changes in RTT or error rates, and notifies you of these changes. Use the <code>show stats-monitor</code> command to see the current administrative state of the stats monitor.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>show stats-monitor</code>
Guidelines	<p>The output contains a configuration table, followed by a table of configured notifications. The notification table only appears if at least one notification is set up with the <code>notify</code> command.</p> <p>Statistics Monitor Configuration is a table with the high-level configuration for the stats monitor. You can edit this configuration with the <code>stats-monitor</code> command and its sub commands.</p> <p>Status is always Enabled.</p> <p>Sampling Interval is the time between the data samples (such as average RTTs and error rates) recorded in the stats-log. The stats monitor records these samples in a series of .csv files. Each .csv file represents one group of external devices (such as back-end CIFS filers or NFS clients for a particular NFS service), or an internal process (such as file migrations or an internal CIFS work queue). You can use <code>show stats-logs</code> to view these .csv files. The default sampling interval is adequate for most sites, but you can use the <code>sampling interval</code> command to change it if necessary.</p> <p>Max Data Size is the storage limit for all statistics (.csv) files stored in the stats-logs partition.</p> <p>Max Raw Data Size is the percentage of Max Data Size permitted for .csv files with “raw” (not “hourly”) in their names.</p> <p>Used Data Size and Used Raw Data Size are the amounts of the above storage that are already used. These are for all statistics (hourly and raw) and raw statistics, respectively.</p> <p>Notification Parameters only appears if at least one notification is active; use the <code>notify</code> command to enable analysis and notification for front-end services or back-end filers. This shows each notification in one row of the table, with the following fields:</p> <p>Applies To identifies the type of service, process, or device that is configured for notifications. You set this with the <code>notify</code> command. This is :</p> <ul style="list-style-type: none"> – “CIFS Services” (related to a <code>cifs</code> front-end service and its clients; these statistics are similar to the CIFS output from <code>show statistics global server</code>), – “NFS Services” (for an <code>nfs</code> service and its clients, similar to the NFS output from <code>show statistics global server</code>), – “CIFS Shares” or “NFS Shares” (back-end <code>shares</code> behind an ARX <code>volume</code>, viewable with <code>show statistics namespace ... summary</code> on an individual share),

Guidelines (Cont.)

Statistics shows the type of notification. This is **Errors** for a notification of an unusual number of errors, or **RespTime** for a notification of an increase in response time. You can use the [moving-average](#) command to enable or disable notifications for this type of event.

Traps indicates whether or not the stats monitor sends an SNMP trap with this notification. This is **Enabled** or **Disabled**, and you can use the [trap](#) command to change the setting.

Metric is always **Mov.Avg**.

Parameters shows the threshold settings that trigger a notification. You can use the [moving-average](#) command to change these thresholds.

Sample bstnA# `show stats-monitor`

shows the configuration of the stats monitor. See [Figure 38.9](#), below.

Related Commands [stats-monitor](#)

Statistics Monitor Configuration

```
-----  
Status                Enabled  
Sampling Interval     300 seconds  
Max Data Size         500 MB  
Max Raw Data Size     80% of Max  
Used Data Size        327 kB  
Used Raw Data Size    274 kB
```

Notification Parameters

Applies To	Statistics	Traps	Metric	Parameters
-----	-----	-----	-----	-----
CIFS Services	Errors	Disabled	Mov.Avg	>100% for 6 Samples
CIFS Services	RespTime	Disabled	Mov.Avg	>100% for 6 Samples
NFS Services	Errors	Disabled	Mov.Avg	>100% for 6 Samples
NFS Services	RespTime	Disabled	Mov.Avg	>100% for 6 Samples
CIFS Shares	Errors	Disabled	Mov.Avg	>100% for 6 Samples
CIFS Shares	RespTime	Disabled	Mov.Avg	>100% for 6 Samples
NFS Shares	Errors	Disabled	Mov.Avg	>100% for 6 Samples
NFS Shares	RespTime	Disabled	Mov.Avg	>100% for 6 Samples

show system tasks

Purpose Use the `show system tasks` command to see a list of subsystem tasks running on the ARX.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show system tasks`

Guidelines **Proc** - is the module slot (number) and processor on which this task is running. This column only appears for platforms with more than one physical processor, such as the ARX-4000.

Subsystem - is the name of the subsystem task. If the task is a script, that fact is noted in parentheses: “(script).”

Instance - is how many instances of the same task are running on this processor. This column does not appear for the ARX-1500 or ARX-2500.

Memory (Kb) - is the amount of memory used by this task.

CPU% - measures the CPU cycles that the task is consuming. This percentage is measured since the last invocation of `show system tasks`. For a measurement of overall CPU usage, use [show processors](#) and/or [show processors usage](#).

CPU-Time - only appears on an ARX-1500 or an ARX-2500. This shows the CPU time used by the current subsystem task since the process last started. The time is expressed in *HH:MM:SS* format.

Samples `bstnA> show system tasks`
shows all subsystem tasks. See [Figure 38.10](#) for sample output.

`stoweA> show system tasks`
shows all subsystem tasks running on an ARX-2500 named “stoweA.”
[Figure 38.11 on page 38-52](#) shows sample output.

stats-monitor

Purpose *** *This is a beta-level command. It does not appear in the CLI unless you use the [terminal beta](#) command to unlock all beta-level commands.* ***

The ARX records the round-trip times and errors between its own software and other external devices (such as back-end filers and front-end clients), as well as time required for migrations and internal operations. You can use the `stats-monitor` command to begin configuring an analysis process that keeps a running average of this data and monitors it for sudden changes. Whenever an issue is discovered, the `stats-monitor` process logs a notification of the issue. Optionally, it also sends an SNMP trap and raises an alarm that is visible with the `show health` command.

You can use the `stats-monitor` command to enter `gbl-stmon` mode and edit the analysis parameters.

Mode `gbl`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `stats-monitor`

Default(s) `None`

Guidelines This is a beta-level command. Use the [terminal beta](#) command to unlock all beta-level commands, including this one.

This command puts you into `gbl-stmon` mode, where you can use commands to change the `stats-monitor` configuration. The `stats monitor` takes periodic samples of errors, computation times, and round-trip times for analysis; you can use the [sampling interval](#) command to change the time between these samples. To change the set of external devices that are analyzed (such as front-end client machines and/or back-end filers), you can use the [notify](#) command. The [notify](#) command also leads to a submode, where you can enable [traps](#) for the group of devices and change the thresholds for the device set's notifications.

The `stats monitor` records its notifications in the `syslog`; you can use [show logs syslog](#) to view them along with all other `syslog` messages. Look for the log component named "SMON_ANALYSIS," or use [grep](#) to search for it.

The raw monitoring data from the `stats monitor` is kept in `.csv` files, which you can list and examine with the [show stats-logs](#) command.

Sample `bstnA(gbl)# stats-monitor`
`bstnA(gbl-stmon)#`
enters the configuration mode for monitoring statistics. From here, you can change parameters for the `stats-monitor` process.

Related Commands [sampling interval](#)
[notify](#)
[show stats-logs](#)
[show stats-monitor](#)
[show health](#)

trap

Purpose *** *This is a beta-level command. It does not appear in the CLI unless you use the [terminal beta](#) command to unlock all beta-level commands.* ***

The ARX records the round-trip times between itself and external devices, such as CIFS clients and back-end filers. The stats-monitor process keeps running averages of these round-trip times and other statistics, and raises alarms in the syslog if the number of errors from an external device increases dramatically, or if the response time from an external host slows dramatically. Use the `gbl-stmon-nfy trap` command to trigger an SNMP trap for these alarms.

Use `no trap` to stop sending an SNMP trap for these alarm conditions.

Mode `gbl-stmon-nfy`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `trap {response-time | errors}`
`no trap {response-time | errors}`

`response-time | errors` is a required choice. This determines the type of error that triggers an SNMP trap: slow response times or excessive errors.

Default(s) `no trap response-time`
`no trap errors`

Guidelines This is a beta-level command. Use the [terminal beta](#) command to unlock all beta-level commands, including this one.

This command enables traps for one set of filers or ARX front-end services, chosen when you use the [notify](#) command to enter the mode.

Refer to the [ARX SNMP Reference](#) for a full list of all traps, along with explanations for each trap and procedures to address the issue. Follow the *Guidelines* for the command, [snmp-server traps](#), to set up a remote host to receive SNMP traps. To manually clear a raised trap, you can use the [clear health](#) command.

To send these traps in E-mail to a set of interested recipients, you can use the [email-event](#) command and its sub-commands to create an e-mail event group.

Sample `bstnA(gbl-stmon-nfy)# trap response-time`
`bstnA(gbl-stmon-nfy)# trap errors`
causes the stats monitor to send SNMP traps for any slow response times or excessive errors.

Related Commands [notify](#)
[snmp-server traps](#)
[clear health](#)
`email-event -> group ... event` or `group (cfg-email-event) stats-monitor`

Network Troubleshooting Tools

Network-Log Components

A *Network-log component* is a source of fastpath-log messages, typically an internal process or group of processes responsible for network traffic. On the original ARX platform, these processes all resided on a single module called the Network Services Module, or NSM. The table below is an alphabetical list of all Network-log components, with a brief description of each.

Log Component	Description
NSM_BSD	Board Support Package.
NSM_CACHE	NSM Cache.
NSM_CIFS	CIFS Proxy on the data plane.
NSM_CM	Connection Manager.
NSM_DGRAM	Datagram.
NSM_DME	Data Mover Engine (DME) proxy on the data plane. This migrates files from one back-end filer to another.
NSM_DMS	NSM DMS.
NSM_DT	Direct Transport.
NSM_ECHO	Packet Echo Service.
NSM_GWMON	Gateway Monitor.
NSM_HA	High-Availability.
NSM_HOT	Hot files.
NSM_IPA	AIPC Server and Client, for internal communication between network processes.
NSM_LIB	Networking Library Functions.
NSM_LOG	System Logging.
NSM_LOOP	Packet Loop Service.
NSM_MSG	Inter-NSM Messaging.
NSM_NAT	The Start of tem message categories.
NSM_NAT	NAT Subsystem.
NSM_NET_HEALTH	Network Health Checks.
NSM_NFS	NFS Proxy on the data plane.
NSM_NFS_CLIENT	NSM NFS client.
NSM_NFS_DNAS	The NFS proxy interactions with DNAS (becoming obsolete).

Log Component	Description
NSM_NFS_FC	NFS File Cache Management Proxy.
NSM_NFS_IPC	The NFS Proxy IPC (obsolete?).
NSM_NFS_MOUNT	Obsolete.
NSM_NFS_SERVER	NFS file server state machine.
NSM_NFS_STATE	The NFS proxy state machine (becoming obsolete).
NSM_NLM	NFS Lock Manager (NLM) proxy on the data plane.
NSM_PING	PING Application.
NSM_PORT	Port Management.
NSM_PRESTO	Presto Console Log.
NSM_ROM	RON Fastpath Proxy.
NSM_SNTP	SNTP.
NSM_STATS	Statistics from the data plane.
NSM_TEME	Fastpath environment-kernel.
NSM_TFTP	TFTP Client.
NSM_TTCP	TTCP Service.
NSM_VIP	VIP Processing.
NSM_VIP_FENCE	VIP Fencing, which can occur when an ARX volume is creating a coordinated snapshot. The VIP fence, while it is raised, prevents clients from changing any volume state while its back-end filers are each taking their snapshots.
NSM_XID_MAP	NFS RPC XID Mapping.

capture merge

Purpose You can use the [capture session](#) command to capture IP traffic and store it in multiple files, where each file is closed and the next is opened as it reaches a size limit. The packet-capture uses the same format as WireShark, an open-source packet analyzer. When you end the capture session, the ARX merges these files into a single file by default. You have the option to end the session without merging the files, or the process may not be able to merge them if the session is somehow interrupted. To merge some capture files in one of these cases, use the [capture merge](#) command.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `capture merge file prefix`

prefix (1-256 characters) is the common prefix of the files to be merged. Use [show capture](#) to see a list of available capture files; choose a prefix that is common to two or more of them from the same capture session. The full file names are “*prefix[id_timestamp].cap*,” where the *id* and the *timestamp* differentiate one file from the other.

Default(s) None.

Guidelines This command merges multiple output files from a single [capture session](#). This only works when the session is finished; use [show capture sessions](#) to see any or all currently-active capture sessions.

The merge makes a single file in chronological order, with the earliest captured packet at the top of the file. To analyze the file from the CLI, you can use [show capture filename](#) to see the full contents or [show capture filename summary](#) to see a summary.

Use [grep](#) to search through the file for a string. You can also use [collect](#), [copy ftp](#), or a similar [copy](#) command to copy a capture file to another machine. You can use WireShark, Tshark, tcpdump, or some other packet analyzer to analyze the file on another host, or you can send it back to F5 Support for their analysis.

Sample `bstnA# capture merge file proxyTraffic`

```
% INFO: Merging 2 capture files into proxyTraffic.cap; this may take up to 1 minute to complete.
```

```
merges all packet-capture files with the prefix, “proxyTraffic.”
```

Related Commands [show capture sessions](#)

[collect](#)
[copy ftp](#)
[copy scp](#)
[copy {nfs|cifs}](#)
[copy smtp](#)
[copy tftp](#)

capture session

Purpose This command captures IP traffic and stores it in a file. The packet-capture uses the same format as WireShark, an open-source packet analyzer.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `capture session session-id ip ip-address [and-ip ip2]
vlan vlan-id file prefix [filesize kilobytes]
[filecount count] [protocol {cifs | non-cifs}]`

`no capture session session-id [no-merge]`

session-id (1-4; limit of 2 on the ARX-VE or ARX-500) is a unique ID for the session, to be used for stopping the capture in the `no` form of the command.

ip-address is the address to match against. This selects the IP packets to capture; any packet with a matching source or destination IP address is included in the capture, in chronological order.

and-ip ip2 (optional) adds a second address to the filter. If you enter this, the capture includes all bidirectional traffic between *ip-address* and *ip2*.

vlan vlan-id (1-4095) focuses on traffic over the specified VLAN.

file prefix (1-255 characters) is the prefix you choose for the output file. The full file name is "*prefix[id_timestamp].cap*," where the *id* and the *timestamp* are only used if the session creates multiple capture files. The file(s) go to the "capture" directory: use [show capture](#) to see the file listing, or `show capture file-name` to view the file.

filesize kilobytes (optional, 1-50,000; 1-1,000,000 for the ARX-4000) truncates the capture at the specified file size. One kilobyte is 1000 bytes, not 1024.

filecount count (optional, 1-10) limits the number of capture files. Each file is no larger than the **filesize**. If you set this count to 2 or more, the capture process rotates the capture files indefinitely. With multiple, rotating capture files, you can use `no capture session session-id` to stop capturing packets.

protocol {cifs | non-cifs} (optional) filters the captured packets. If you choose **cifs**, the capture file only includes packets to or from CIFS-related ports: UDP/88, TCP/88, UDP/137, UDP/138, TCP/139, and/or TCP/445. If you choose **non-cifs**, the capture file includes packets to or from any *other* ports.

no-merge (optional, for the `no` form of the command) only applies to a capture session where the **count** is two or more files. Without this, the `no` form of the command merges all files from a multi-file session. This option prevents the merge.

**Syntax: Capture All
Proxy-IP Traffic**

`capture session session-id proxy-all file prefix [filesize
kilobytes] [filecount count] [protocol {cifs | non-cifs}]`

proxy-all captures all traffic with any proxy-IP address as its source or destination. Use [show ip proxy-addresses](#) to show all proxy-IP addresses on the switch. No VLAN ID is required for this syntax; the VLAN is implicit. The ARX-VE only has a single proxy-IP address, so it does not support this option.

Default(s) **filesize** - 16,000 kilobytes
filecount - 1

Guidelines This command starts a capture session, similar to the [monitor](#) command. Unlike the [monitor](#) command, this does not require a network analyzer.

The preparation for a packet capture can be time-consuming, especially on a busy system. The CLI prints a message after you enter this command, warning of the possible delay.

To see any or all currently-active capture sessions, use [show capture sessions](#). Use the [show capture](#) command to view the all capture files in a directory listing, or to view a capture file's contents. Use [grep](#) to search through the file for a string. The [tail](#) ... [follow](#) command displays the capture file as it grows. You can also use [collect](#), [copy ftp](#), or another [copy](#) command to copy a capture file to another machine, where you can examine it with WireShark, TShark, tcpdump, or some other packet analyzer.

The [no capture](#) command immediately stops the current capture. If you use the [no-merge](#) option with a multi-file capture, the session creates multiple capture files. Multiple capture files also result when a multi-file session is interrupted by an ARX reboot. To merge all the files from a particular capture session into a single file, use the [capture merge](#) command.

Jumbo frames are not included in any capture files. The [jumbo mtu](#) command enables jumbo frames. If you use jumbo frames, you can use the [monitor](#) command with a network analyzer to capture your network traffic. The [monitor](#) command requires an ARX with multiple network interfaces.

Samples `bstnA# capture session 1 ip 192.168.25.19 vlan 25 file clientCap`
captures all traffic to and from a particular IP address. The file name is "clientCap."

`bstnA# capture session 2 proxy-all file proxyTraffic filesize 150 filecount 2`
captures all traffic to or from the proxy-IP address(es). This capture session is limited to two files of 150 Kbytes each. The capture session continues indefinitely, rotating the two files, until someone uses `no capture session 2` to stop it.

`bstnA# no capture session 2`
immediately stops capture session 2. This command merges the two files produced by the capture. The resulting file is named "proxyTraffic.cap."

clear statistics filer connections

Purpose	Use this command to clear the connection statistics for a given back-end filer, or for all of them.
Mode	priv-exec
Security Role(s)	storage-engineer or crypto-officer
Syntax	clear statistics filer connections clear statistics filer <i>ext-filer-name</i> connections <i>ext-filer-name</i> (1-64 characters) specifies a single filer where you want to clear all connection statistics. If you omit this, the command clears the connection statistics for all filers. This identifies the external filer by its configured name on the ARX. Use show external-filer to display all configured external filers.
Default(s)	None
Guidelines	The show statistics filer connections command shows current connection counts between the ARX's software and its back-end filers. Use this command to clear those connection counters for one filer, or all of them. The CLI prompts for confirmation before clearing the statistics; enter yes to proceed.
Sample	bstnA# clear statistics filer fs2 Clear the connection statistics on filer 'fs2'. Are you sure? [yes/no] yes clears the connection statistics for the external filer named "fs2."
Related Commands	show statistics filer connections show external-filer

clear statistics global server

Purpose Use this command to clear the client-traffic statistics for a global server.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics global server fqdn`

fqdn (1-64 characters) is the fully-qualified domain name (for example, “myserver.organization.org”) for a global server. Use [show global server](#) to see a list of global servers.

Default(s) None

Guidelines The [show statistics global server](#) command shows the high-level traffic between a global server and its clients. Use this command to clear the traffic counters for one global server.

The CLI prompts for confirmation before clearing the statistics; enter **yes** to proceed.

Sample bstnA# `clear statistics global server ac1.medarch.org`
Clear statistics of global server ac1.medarch.org.

Are you sure? [yes/no] **yes**

Related Commands [show statistics global server](#)
[show global server](#)

drop filer-connections

Purpose Use the `drop filer-connections` command to drop all connections to a back-end filer or server. This command may produce a noticeable interruption for your clients; use it only for a filer that is overwhelmed with ARX connections.

Modes `priv-exec`

Security Role(s) `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

Syntax `drop filer-connections filer [processor slot.processor]`

filer (1-64 characters) identifies the filer to be disconnected (for example, “smb-1”). The `show external-filer` command lists all filers defined on the ARX.

slot.processor (for example, 2.7) focuses on one network (or fastpath, or NSM) slot and processor. If you use this option, only the identified network processor drops its connections to the filer.

Default(s) None

Guidelines The CLI prompts for confirmation before dropping any connections; enter `yes` to proceed.

This is useful for a Tier-2 filer that is currently overwhelmed with TCP traffic, or is experiencing connectivity issues that may be related to a high number of TCP connections. To set a limit on the number of CIFS connections from the ARX to this filer, use the `cifs connection-limit` command. If you set a lower limit than the current one, you have the option to wait for CIFS clients to disconnect gracefully. This causes the ARX to block any new CIFS connections to the filer until enough currently-connected clients drop off. You can use this command to reverse that decision, immediately dropping all connections to the filer and going to the lower limit.

You can use `nfs tcp connections` to set a limit on the number of NFS/TCP connections to the filer.

You can use the `show filer connections` command to monitor the current connections to a filer.

◆ **Note**

The NSM re-establishes its NFS connections as soon as they are dropped. Similarly, CIFS-client applications may re-establish connections as soon as they are disconnected. Therefore, this command may not have any noticeable affect on the `show filer connections` output.

To drop a CIFS-client connection, you can use `drop cifs-service user-session`.

Sample bstnA# **drop filer-connections smb1 processor 2.6**
Drop the connections from processor 2.6 to filer smb1.

Proceed? [yes/no] **yes**

bstnA#

disconnects all CIFS/TCP connections between NSM processor 2.6 and the
“smb1” filer.

Related Commands [show filer connections](#)
[drop cifs-service user-session](#)
[cifs connection-limit](#)

expect nslookup

Purpose Use this command to perform an **nslookup** from the ARX, thereby testing the DNS lookup configuration.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `expect nslookup ip-or-hostname [timeout seconds]`

ip-or-hostname (1-128 characters) is the IP address or host name to look up (for example, “172.16.46.2,” “myserver3,” or “juser-pc.myco.com”).

seconds (optional, 1-2096) sets a time limit on the nslookup operation. If you omit this and the command takes excessive time, you can use <Ctrl-C> to stop it.

Default(s) *seconds* - 21,600 (6 hours)

Guidelines This command calls a remote DNS server to look up an IP address or machine name. The output is the IP address and fully-qualified domain name (FQDN) for the given host.

The lookup fails if none of the ARX’s DNS servers are reachable. Use the [show ip domain](#) command to show all configured DNS servers. To add a new one, use the [ip name-server](#) command.

Sample `bstnA# expect nslookup bboard.wwmed.com`

```
bboard.wwmed.com is an alias for rh1.wwmed.com.  
rh1.wwmed.com has address 192.168.25.19  
looks up the host named “bboard.wwmed.com.”
```

Related Commands [show ip domain](#)
[ip name-server](#)

expect show firewall

Purpose The firewall configuration determines which IP packets are accepted into the control-plane processor (processor 1.1) and which packets are dropped. Use **expect show firewall** to show the current firewall configuration.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax **expect show firewall [timeout seconds]**

seconds (optional, 1-2096) sets a time limit on the show-firewall operation. If you omit this and the command takes excessive time, you can use <Ctrl-C> to stop it.

Default(s) *seconds* - 21,600 (6 hours)

Guidelines These firewall rules apply to out-of-band management (MGMT) port. This is on the ACM or control plane.

This command shows three ordered lists of firewall rules: INPUT (packets coming in), FORWARD (packets to be forwarded to another station), and OUTPUT (packets to be sent out). Every packet is compared to one of these lists depending on its path (for example, all incoming packets are compared to the INPUT list).

Within each list, the packet is compared to the rules in order. Each row is one rule:

pkts is the number of packets accepted by the rule.

bytes is the total number of bytes from the above packets.

target (typically ACCEPT or DROP) determines what to do with a matching packet.

The remaining flags are match criteria.

Use [expect show ifconfig](#) to show configurations for all interfaces (internal and external) on the control-plane processor.

Sample bstnA# **expect show firewall**
shows the firewall rules for the ACM processor. See [Figure 39.1](#) for sample output.

Related Commands [expect show ifconfig](#)

expect show ifconfig

- Purpose** Use `expect show ifconfig` to show configuration details for all ACM-processor interfaces.
- Mode** `priv-exec`
- Security Role(s)** `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`
- Syntax** `expect show ifconfig [timeout seconds]`
- seconds* (optional, 1-2096) sets a time limit on this command. Whether or not you set this timeout, you can use `<Ctrl-C>` to stop the process at any time.
- Default(s)** *seconds* - 21,600 (6 hours)
- Guidelines** These interfaces are on the ACM.
- The output is labeled with interface names in the left column. Next to each interface name are the configuration details for the interface. Most of these interfaces are internal to the ARX, used for communication with other internal processors.
- The interface names are in the following format: *interface.vlan:num*. The *interface* is the name of the interface (such as `eth0`), the *vlan* is the VLAN number, and the *num* is different for every IP alias that is used by the *interface.vlan*.
- Use [expect show firewall](#) to show the firewall rules used by the ACM processor.
- Sample** `prtlnA# expect show ifconfig`
shows the interface configurations for the ACM processor on “prtlnA.” See [Figure 39.2 on page 39-16](#) for sample output.
- Related Commands** [expect show firewall](#)

expect show netstat

Purpose Use `expect show netstat` to show the current network status at the ACM processor.

Mode `priv-exec`

Security Role(s) `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

Syntax `expect show netstat [timeout seconds]`

seconds (optional, 1-2096) sets a time limit on this command. Whether or not you set this timeout, you can use `<Ctrl-C>` to stop the process at any time.

Default(s) *seconds* - 21,600 (6 hours)

Guidelines Use [expect show ifconfig](#) to show configurations for all interfaces (internal and external) on the ACM processor. The [expect show firewall](#) command shows the processor's firewall rules, which determine whether to drop or accept IP packets.

Sample `bstnA# expect show netstat`
shows the network status for the ACM processor. See [Figure 39.3](#) for sample output.

Related Commands [expect show ifconfig](#)
[expect show firewall](#)

Figure 39.3 Sample Output: expect show netstat

```
bstnA# expect show netstat

Active Internet connections (servers and established)
Proto Recv-Q Send-Q Local Address           Foreign Address         State
tcp      0      0 169.254.70.1:35264     0.0.0.0:*               LISTEN

...
```

expect traceroute

Purpose Use this command to show all IP-router hops from the ACM processor to a given IP address.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `expect traceroute ip-destination [timeout seconds]`

ip-destination (1-128 characters) is the destination-IP address (for example, 172.16.46.2).

seconds (optional, 1-2096) sets a time limit on this command. Whether or not you set this timeout, you can use <Ctrl-C> to stop the process at any time.

Default(s) *seconds* - 21,600 (6 hours)

Guidelines This command sends a packet from the ACM processor and shows each IP router that forwards the packet. The packet starts at the MGMT interface (use [show interface mgmt](#) to find this address) or an inband (VLAN) management interface ([show interface vlan](#)).

If the packet does not reach its next hop, it prints asterisks (*) to mark the time. Use <Ctrl-C> to escape the command.

Use the [ping](#) command to see if an address is reachable from various processors. Use [expect show ifconfig](#) to show configurations for all interfaces (internal and external) on the ACM processor. The [expect show firewall](#) command shows the processor's firewall rules, which determine whether to drop or accept IP packets.

Sample bstnA# `expect traceroute 192.168.25.19`

```
1 192.168.25.1 0.587 ms 0.553 ms 0.491 ms
2 192.168.25.19 0.367 ms 0.363 ms 0.367 ms
```

shows that there are two hops from the ACM processor to the machine at 192.168.25.19.

Related Commands [ping](#)
[expect show ifconfig](#)
[expect show firewall](#)

expect ttcp

Purpose Test TCP (TTCP) is an open-source benchmarking tool for testing TCP (and UDP) connections. Use this command to run a TTCP test between two ARXes (over a RON tunnel) or between an ARX and a remote TTCP server.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `expect ttcp server [timeout seconds]`
`expect ttcp transmit ttcp-server-ip [timeout seconds]`

seconds (optional, 1-2096) sets a time limit on this command. Whether or not you set this timeout, you can use <Ctrl-C> to stop the process at any time.

ttcp-server-ip (1-128 characters) is the IP address of a TTCP server (for example, 172.16.46.2). If the TTCP server is another ARX on the RON, use the .1 address on the switch's private subnet (for example, 169.25.100.1). Use [show ron route](#) to find the private subnet.

Default(s) *seconds* - 21,600 (6 hours)

Guidelines To test the throughput between two ARXes, you must first prepare the receiving switch to serve TTCP. Run the `expect ttcp server` command on the receiving switch. This blocks the CLI until the optional **timeout** expires, or until you press <Ctrl-C>. Then go to the sending switch to start the TTCP test.

The `expect ttcp transmit` command invokes a 10-second TTCP test to any server that supports TTCP. This can be any filer, client, or other station on the network that can receive TTCP transmissions, or it can be another ARX on the same Resilient Overlay Network (RON; see [interface ron](#)). You must identify the server first, as described above.

The transmission can hang for longer than one minute if the IP address is incorrect. You can use the optional **timeout** or <Ctrl-C> to cancel the test.

The transmit test ends with a one-line report containing the following fields:

nnnn.nnn MB / 10.00 Sec = xxx.xxxx Mbps is the amount of data transmitted in 10 seconds.

aa %TX is the percent-CPU utilization at the transmitting switch's ACM processor.

bb %RX is the percent-CPU utilization reported from the TTCP server.

When a switch-to-switch test is over, you can go back to the server switch and press <Ctrl-C>.

The ARX can only receive TTCP from another ARX in the same RON.

Use the [ping](#) command to see if an address is reachable from various processors. Use [expect show ifconfig](#) to show configurations for all interfaces (internal and external) on the ACM processor. The [expect show firewall](#) command shows the processor's firewall rules, which determine whether to drop or accept IP packets.

Sample

```
prtlndA# expect tcp server timeout 600  
Waiting for TTCP client. Hit ^C to abort...
```

uses the “prtlndA” switch as the TTCP server. It blocks the CLI for up to 600 seconds (10 minutes), waiting for a transmission from another ARX.

This takes place on the transmitting switch, named “bstnA:”

```
bstnA# show ron route
```

```
Default Policy
```

```
-----
```

Destination	Subnet	via Tunnel	Milliseconds
gffstnA	169.254.104.0/24	toGoffstown	0.1
minturnA	169.254.80.0/24	toMinturn	0.1
provA	169.254.127.0/26	toProvidence	0.1
prtlndA	169.254.66.0/24	toPortland	0.1
prtlndB	169.254.96.0/24	toPortlandB	0.1

```
bstnA# expect tcp transmit 169.254.66.1
```

```
Starting 10 second TCP transmit test. Hit ^C to abort...  
586.5138 MB / 10.00 sec = 491.9229 Mbps 12 %TX 23 %RX
```

```
bstnA#
```

Shows the private subnet for the “prtlndA” switch, then uses the subnet to send a TTCP test to the server.

To unblock the CLI on the server switch, “prtlndA,” you can wait for the timeout or press <Ctrl-C>:

```
Waiting for TTCP client. Hit ^C to abort... <Ctrl-C>  
prtlndA#
```

Related Commands [ping](#)
 [expect show ifconfig](#)
 [expect show firewall](#)

logging fastpath component

Purpose Each group of network-log messages, known as a network-log *component*, has a separately-tunable *logging level*. Level 1 is the most terse, displaying non-recoverable errors only; level 10 is the most verbose, displaying all levels of messages including per-packet logs. The messages appear in a log file named “fastpath.” Use the `logging fastpath component` command to set a network-logging level.

Use the `no` form of this command to disable network logging for a component.

Mode `cfg`

Security Role(s) `network-engineer` or `crypto-officer`

Syntax `logging fastpath component nsm-component Level`
`no logging fastpath component nsm-component`

nsm-component (1-128 characters) is the network component to tune. See [Network-Log Components](#), on page 39-3 for a complete list of network components.

level (0-10) sets the logging level for the component. Level 0 disables all logs from the component. Level 1, as mentioned above, logs only non-recoverable errors. Levels 2 and 3 include warnings and recoverable errors. Level 4 adds logs about internal-configuration changes. Levels 5-10 include per-packet logs, where level 10 is the most verbose.

◆ Important

Any level greater than 1 can significantly degrade networking performance on the ARX. Use this feature only under the strict guidance of F5 personnel.

Default(s) `level - 1`

Guidelines The first time you enter any `logging fastpath` command, the CLI issues a warning about the performance impact of network (also called “NSM”) logging. If this appears, enter `yes` to proceed.

This is similar to the `logging level` command, which sets logging levels for software components on the or ACM. This affects the logging level on all network processors where logging is enabled; use the `logging fastpath processor` command to enable logging on a processor. The `show fastpath logging` command shows which network processors are currently enabled for logging, along with the log-level settings for each component.

If you set the logging level higher than zero, you can filter the logs for a given IP address, host name, or any other search string. This reduces the size of the fastpath file and focuses the logs on a particular problem. Use the `logging fastpath component ... filter` command to implement filtering for an network-log component.

From any mode, use `show logs fastpath` or `grep pattern logs fastpath` to view the log messages in the fastpath file.

Samples `bstnA(cfg)# logging fastpath component NSM_CIFS 6`

Enabling fastpath logging adversely impacts the performance of the switch.

Proceed? [yes/no] **yes**

sets the NSM_CIFS component to log level 6. On every network processor where logging is enabled, the NSM_CIFS component starts logging messages up to and including level-6 messages. This can be verbose on a busy system.

`bstnA(cfg)# no logging fastpath component NSM_CIFS`

disables log messages from the NSM_CIFS component.

Related Commands [logging fastpath processor](#)
[logging fastpath component ... filter](#)
[show fastpath logging](#)

logging fastpath component ... filter

Purpose Each source of network-log messages, known as an network-log *component*, can filter its messages before adding them to the log file. This reduces the stress on network processors and can help with diagnosing a network problem. Use the `logging fastpath component ... filter` command to filter the log messages from a particular network component.

Use the `no` form of this command to remove one match string from the log filter.

Mode `cfg`

Security Role(s) `network-engineer` or `crypto-officer`

Syntax `logging fastpath component nsm-component filter match-string {include | exclude}`

`no logging fastpath component nsm-component filter match-string`

nsm-component (1-128 characters) is the network component to filter. See [Network-Log Components](#), on page 39-3 for a complete list of network components.

match-string (optional, 1-80 characters) is a string to match against. Quote the string if it contains any spaces. Any messages that match this string are added to the “fastpath” log file. To include log messages that match multiple strings (for example, multiple IP addresses), repeat this command with each desired string. If a log message matches *any* of the entered strings, the logging component adds it to the “fastpath” file.

include | exclude is a required choice. The **include** choice causes the filter to include any network-log messages that match the *match-string*. The **exclude** option reverses the filter; a message is *excluded* from the log if it matches the *match-string*.

Default(s) `no filter`

Guidelines The first time you enter any `logging fastpath` command, the CLI issues a warning about the performance impact of network logging. If this appears, enter **yes** to proceed.

Use [logging fastpath processor](#) to activate logging for one or more network processors, then use the [logging fastpath component](#) command to set the logging level for an network-log component. This command filters the messages from the component; the filter is ineffective for any component(s) where the logging level is 0 (zero).

Use [show fastpath logging](#) to verify the filter settings for each component.

From any mode, use [show logs fastpath](#) or [grep pattern logs fastpath](#) to view the log messages in the fastpath file.

Samples `bstnA(cfg)# logging fastpath component NSM_CIFS filter 172.16.22.100`
`include`
`bstnA(cfg)# logging fastpath component NSM_CIFS filter 192.168.25.31`
`include`
`bstnA(cfg)# logging fastpath component NSM_CIFS filter 192.168.25.32`
`include`

filters the NSM_CIFS component for three IP addresses. Any NSM_CIFS log message that matches any of these IP addresses is included in the fastpath file.

`bstnA(cfg)# no logging fastpath component NSM_CIFS filter 192.168.25.32`
removes one IP address from the NSM_CIFS filter.

`bstnA(cfg)# logging fastpath component NSM_VIP filter 192.168.25.10`
`exclude`
`bstnA(cfg)# logging fastpath component NSM_VIP filter 192.168.25.12`
`exclude`

filters the log messages from the NSM_VIP component. This excludes all log messages that match either “192.168.25.10” or “192.168.25.12;” all other messages from the component are included.

Related Commands [logging fastpath processor](#)
[logging fastpath component](#)
[show fastpath logging](#)

logging fastpath processor

Purpose A network processor can send log messages to the “fastpath” log file for a detailed diagnosis of networking issues. Use the `logging fastpath processor` command to activate logging for one network processor.

Use the `no` form of this command to stop the processor from adding any log messages to the file.

Mode `cfg`

Security Role(s) `network-engineer` or `crypto-officer`

Syntax `logging fastpath processor slot.processor`
`no logging fastpath processor slot.processor`

slot.processor (for example, 1.4, 2.7, or 3.1) identifies a slot and network processor. Use the `show processors` command for a full list of processors on the ARX.

Default(s) `no logging`

Platforms ARX-500, ARX-2000, and ARX-4000

Guidelines The first time you enter any `logging fastpath` command, the CLI issues a warning about the performance impact of network logging. If this appears, enter `yes` to proceed. Several network *components* run on a network processor, where each component can generate its own set of log messages in the “fastpath” log file. The network components are listed earlier in the chapter; see [Network-Log Components](#), on page 39-3. Each component has a tunable logging level that you can set with the `logging fastpath component` command. By default, all of the logging components are set at a very terse logging level, so as not to overwhelm the network processor(s) that have logging enabled. If you raise the logging level to diagnose a problem, you should limit the volume of logging messages with the `logging fastpath component ... filter` command.

◆ Important

Too much logging may overwhelm a network processor, possibly resulting in a service interruption. Only use network logging under the guidance of F5 personnel.

Use `show fastpath logging` to show which processors are enabled for logging. This also shows all configured logging levels and filter settings.

From any mode, use `show logs fastpath` or `grep pattern logs fastpath` to view the network-log messages in the fastpath file.

Samples `bstnA(cfg)# logging fastpath processor 3.1`

Enabling fastpath logging adversely impacts the performance of the switch.

Proceed? [yes/no] **yes**

enables logging for processor 1 in slot 3.

`bstnA(cfg)# no logging fastpath processor 4.4`

disables logging for processor 4 in slot 4.

Related Commands [logging fastpath component](#)
[logging fastpath component ... filter](#)
[show fastpath logging](#)
[show logs](#)
[grep](#)

monitor

Purpose Use the `monitor` command to configure port mirroring. *Port mirroring* mirrors the Ethernet traffic on one or more ports onto another port, where the destination port typically has a network analyzer attached. The network analyzer can therefore see all traffic going through the source interface(s) in real time.

◆ Important

A service interruption can occur if the destination interface is over subscribed. Use this command only as advised by F5 Technical Support.

Use the `no` form of the command to stop port mirroring.

Mode `cfg`

Security Role(s) `network-engineer` or `crypto-officer`

Syntax `monitor {module | diagnostic}
 source-interface slot/port {rx | tx | both}
 destination-interface slot/port`

`no monitor {module | diagnostic}
 source-interface slot/port {rx | tx | both}
 destination-interface slot/port`

module | diagnostic is a required choice.

module enables you to mirror from one external port to another on the same module.

diagnostic is for internal use only.

source-interface *slot/port* (2/1-14 on ARX-4000; 1/1-12 on ARX-2000) identifies a port to be monitored (for example, 2/3 or 1/6).

rx | tx | both is a required choice, where you specify the direction(s) of the packets to monitor (rx = received packets; tx = transmitted packets; both = both received and transmitted packets).

destination-interface *slot/port* (same ranges as for **source-interface**) identifies an external port where the network analyzer is located; for example, 2/1. Choose a destination port with equal or greater bandwidth than the source port.

Default(s) `None`

Platforms `ARX-2000` or `ARX-4000`

Guidelines Before you use this command, you typically connect a network analyzer at the destination port.

The monitor module command may overwhelm the destination interface, causing client/server packets to be dropped. The CLI prompts you with a warning before mirroring any packets; enter **yes** to continue.

Use [show interface summary](#) to show all ports and their slots.

You can issue this command more than once to mirror traffic from more than one port. If there is more traffic from the source port than the destination port can carry, frames are dropped; there is no buffering at the destination port.

Remember to shut down a monitor session when you finish diagnosing the problem. Port mirroring causes a heavy load on the monitored port, which must duplicate every frame and forward it to the network analyzer's port. Use the [show monitor](#) command to see if there is an active monitor session.

Samples `bstnA(cfg)# monitor module source-interface 2/6 both
destination-interface 2/2`
Warning: Oversubscription of the destination monitor port may result in a service interruption. Proceed only upon advice from Technical Support.

Are you sure? [yes/no] **yes**
monitors port 2/6. A network analyzer at port 2/2 will see all packets, both transmit and receive, going through port 2/6.

`bstnA(cfg)# no monitor module`
stops monitoring on the port.

[show interface summary](#)

ping

Purpose Use the `ping` command to send one or more pings (ICMP ECHO requests) to a specified IP address.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax

```
ping destination-ip [count number] [framesize bytes]
ping destination-ip from slot.processor [count number]
    [framesize bytes]
ping destination-ip source source-ip [count number]
    [framesize bytes]
ping destination-ip from slot.processor source source-ip
    [count number] [framesize bytes]
```

destination-ip is the IP address to receive the ping.

count number (optional, 1-10,000) limits the number of pings to send.

from slot.processor (optional) is not available on the ARX-1500, ARX-2500, or ARX-VE. This identifies a slot and processor to send the ping (for example, 2.3). Use the [show processors](#) command for a full list of processors on the ARX. You can ping from processor 1.1 to test the out-of-band (MGMT) network processor and connection.

source source-ip (optional) is the source-IP address to send in the ICMP ECHO request. If you omit the **from** clause, the CLI chooses an appropriate processor. The ICMP ECHO response will be returned to this address; if you set the source processor with **from** and the IP does not reside on that processor, the ping output shows “no response.”

framesize bytes (optional) is the size of the packet that you want to send. This is an extra payload that the software adds to the ICMP ECHO header.

Default(s) *count number* - infinite; use <Ctrl-C> to stop the pings.

from slot.processor -

if you choose a *source-ip*: the processor that is associated with the source IP.

without a *source-ip*: the first available processor. This starts with the first network processor (for example, 1.2 in an ARX-2000). If no network processors are available, the management processor (1.1) sends the ping.

source source-ip - the best source IP to reach the *destination-ip*, as chosen by the sending processor’s routing table.

framesize bytes - 0 (zero)

Guidelines If you do not use the `count` clause to limit the number of pings, use `<Ctrl-C>` to stop them.

For a list of proxy-IP addresses, which network processors use to communicate with filers and servers, use the `show ip proxy-addresses` command. The output maps each proxy-IP address to a particular processor. For a list of virtual-IP addresses, which processors use to communicate with the client side, use the `show global server` command. The `show interface vlan` command produces a list of in-band (VLAN) management interfaces, and the `show interface mgmt` command shows the IP for the out-of-band Mgmt interface on the front panel. Use the `show ip route` command to view the IP routing tables for all processors on the switch.

The output is typical for ping implementations. The last column shows the source processor used for the ping, in `slot.processor` format, for platforms that support a specific processor source. If you specified only the `source-ip` in the command, the last column shows the source address instead. A summary of all pings appears at the end of the output; see *Samples*, below.

You can use the `expect traceroute` command to show all the IP-router hops from the ACM processor to any given IP address.

Samples bstnA> ping 172.16.100.83
PING 172.16.100.83 (172.16.100.83) 0 data bytes
8 bytes from 172.16.100.83: icmp_seq=1 ttl=62 time=3 ms. from 2.3

show capture sessions

Purpose	You can invoke an IP capture session that collects certain IP packets and streams them into a file. Use the <code>show capture sessions</code> command to view all such sessions.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<code>show capture sessions</code>
Guidelines	<p>You can capture IP traffic into a file with the <code>capture session</code> command. This command shows a list of all currently-running sessions.</p> <p>The output is split into two tables. Each session appears on its own row. The first table shows the choices made with the <code>capture session</code> command. It has the following columns:</p> <p>Session identifies the session by its ID.</p> <p>Ip is the address to match against, if any. Any packet or source or destination address matches this is included in the capture file. This is “proxy-all” if the session is capturing traffic from all proxy-IP addresses at once.</p> <p>Additional Ip is another address to match against, if any. Any packet exchanged between this address and the address above is included in the capture. As above, “proxy-all” indicates that the session is capturing traffic to all proxy-IP addresses at once.</p> <p>VLAN is the VLAN ID that is being scanned for matching IP packets. If this is 1, a frame with no specified VLAN ID can also match.</p> <p>File Size is the maximum size of the file, if any. You can set this with an option in the <code>capture session</code> command.</p> <p>File Count is the maximum number of files that the session can produce.</p> <p>The second table shows the current state of the each capture and the prefix for its output files:</p> <p>Session identifies the session by its ID.</p> <p>State is either “Capturing” or “Complete.”</p> <p>File Name is the prefix of all the output files. Use the <code>show capture</code> command to show a list of all capture files, or to show the contents of any of them. To maintain this directory, use the <code>copy</code>, <code>rename</code>, <code>grep</code>, and <code>delete</code> commands.</p>
Sample	<pre>bstnA> show capture sessions</pre> <p>shows all active capture sessions. See Figure 39.4 on page 39-35 for sample output.</p>

1	Capturing	ntaps.cap
2	Capturing	fsrvr.cap

show fastpath logging

Purpose You can enable one or more network processors to send log messages to a “fastpath” log file. The network-log messages are divided into groups based on the software components that generate them. You can set a logging level for each network-software component, from 1 (terse; shows only the most-urgent messages) to 10 (extremely verbose). You can also filter each logging component so that it logs messages that are relevant to a particular network issue. Use the `show fastpath logging` command to list all network processors that are configured for logging along with the log levels and filtering for each network component.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show fastpath logging`

Guidelines The output contains two tables. The first shows the network processors that have logging enabled:

Slot is the slot number , and

Processor is the processor that is actively logging its messages. Use the `logging fastpath processor` command to enable logging on a network processor.

The second table shows all network-log components with a non-default logging level and/or filtering enabled:

Component is an network-log component with non-default settings. A full list of network-log components appears earlier; see [Network-Log Components](#), on page 39-3.

Trace Level is the logging level, where 1 is the most-terse level and 10 is most-verbose. Use the `logging fastpath component` command to change this.

Filter Type is “inclusive” or “exclusive.” This determines whether a log message containing the Filter String is included in or excluded from the “fastpath” log. This is set with the `logging fastpath component ... filter` command.

Filter String is a match string that the network component applies to each log message. This is also set with the `logging fastpath component ... filter` command.

Sample `bstnA(cfg)# show fastpath logging`
shows the logging configuration for the network (or “fastpath”) processes. See [Figure 39.5](#), below.

NSM_CIFS		inclusive	172.16.100.183

show fastpath resources

Purpose Use the `show fastpath resources` command for a detailed breakdown of software resources used on a network processor.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show fastpath resources [slot.processor | ip-address ip-address]`

slot.processor (optional: 2.1-12 on ARX-4000; 1.2-5 on ARX-2000; 1.2 on ARX-500 or ARX-VE) focuses the output on a single network processor (for example, 2.4). If you omit this, the report shows the resources used on all of the ARX's network processors. Use the [show processors](#) command for a full list of processors on the ARX.

ip-address (optional) focuses the output on an IP address. Each IP address is handled by a particular network processor; this finds the correct processor and reports on the resources used there.

Guidelines If you enter an IP address, the top of the output shows the network processor that serves the address. You can also use [show ip address](#) to find the processor assigned to the address.

The output contains the following tables for each network processor:

- NFS resources,
- CIFS resources,
- System resources,
- Presto resources, and
- IP ports.

This data is difficult to interpret without knowledge of the network software's internal processes. Contact F5 Support for further information.

Samples `bstnA(cfg)# show fastpath resources 2.1`
shows the resources used for a single NSM processor. See [Figure 39.6](#), below.

`bstnA(cfg)# show fastpath resources ip-address 192.168.25.23`
shows the resources used on the NSM processor for 192.168.25.23. See [Figure 39.7 on page 39-41](#).

show filer connections

Purpose Use the `show filer connections` command to show the current TCP and UDP connections from the network processors to a given back-end filer.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show filer connections {ext-filer-name | ip-addr ip}`

ext-filer-name (optional, 1-64 characters) identifies the external filer by its configured name. Use [show external-filer](#) to display all configured external filers.

ip is the IP address of the filer.

Guidelines The output is a table with one line per connection to the filer.

Proc is the network processor at one end of the connection, in *slot.processor* format.

Proxy Ip is proxy-IP address that the network processor is using. Use [show ip proxy-addresses](#) to show all proxy-IP addresses on the switch.

Filer Port shows the transport protocol (TCP or UDP) and the port number being used at the filer.

Conn. is the number of connections from the network processor to the filer.

You can use the [drop filer-connections](#) command to drop all connections to a filer. The NSM re-establishes its TCP connections immediately, and CIFS-client applications may do the same; therefore, this output may not change after you run the `drop filer-connections` command.

The [show statistics filer connections](#) command shows statistics on filer connections over time.

Sample `bstnA(cfg)# show filer connections ip-addr 192.168.25.19`
shows connections to the filer at 192.168.25.19. See [Figure 39.8](#) for sample output.

Related Commands [drop filer-connections](#)
[show statistics filer connections](#)

show monitor

Purpose Use the `show monitor` command to show the configuration for any active monitoring session.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show monitor`

Platforms ARX-2000 and ARX-4000

Guidelines A monitor session, also called port mirroring, duplicates frames from one port to another. You can connect a network analyzer to the destination port to examine the traffic on the source port. Use the [monitor](#) command to start or stop a port-monitoring session. Remember to stop a monitoring session if it is not in use; the duplication is a performance strain for both the source and destination ports.

Sample `bstnA(cfg)# show monitor`

```
Monitor Session: System
Source : Slot 2 Port 9
Destination :Slot 2 Port 12
Mode: Rx
```

shows the only currently active monitoring session.

Related Commands [monitor](#)

show statistics filer connections

Purpose Use the `show statistics filer connections` command to show filer-connection statistics for a particular filer, or for all filers.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics filer connections`
`show statistics filer filer connections [processor slot.proc]`

filer (optional, 1-64 characters) identifies a particular filer (for example, “nas10”). The [show external-filer](#) command lists all filers defined on the ARX. If you omit this, the output contains a table with summary statistics for all connected filers.

slot.proc (optional: 2.1-12 on ARX-4000; 1.2-5 on ARX-2000; 1.2 on ARX-500 or ARX-VE) focuses on one NSM slot and processor. If you use this option, the output focuses on connections from the identified NSM processor.

Guidelines: Summary Output The output from the simplest syntax, `show statistics filer connections`, shows a table of current connections and maximum connections for all external filers. Each filer appears on one row with the following fields:

Filer is the name of the external filer, as defined on the ARX.

Connections

Current is the current number of connections to the filer. You can use [cifs connection-limit](#) to set a maximum number of CIFS connections, and you can use [nfs tcp connections](#) to set a ceiling on NFS/TCP connections.

Max is the maximum number of simultaneous connections to the filer since the last reboot, or since the last time someone ran the [clear statistics filer connections](#) command.

Guidelines: Detailed Output

If you specify a filer in the command, the output contains two tables with detailed statistics. The CIFS table contains the following fields:

Connection limit is the maximum number of connections allowed to this filer, if any. You can use the [cifs connection-limit](#) command to set this limit.

Current data connections is the current number of connections through the data plane. That is, this is the number of connections that are directly related to client connections, and do not come from the control plane (processes on the ACM).

Current control connections counts the current connections from processes on the ACM. These are processes that do not directly relate to any client connections, such as connections from the policy engine or connections that require calculations at the control plane.

Max connections (data+control) is the most simultaneous connections to this filer since the last reboot, or since the last time someone ran [clear statistics filer connections](#).

Time of Max connections is the date that the above maximum occurred.

Current data sessions shows the number of data sessions that are currently connected to the filer. Each data connection can hold multiple data sessions, where each session may correspond to a different client. This is the number of sessions that are directly related to client activity, and do not come from the control plane (processes on the ACM).

Max data sessions is the most simultaneous sessions on this filer since the last reboot, or since the last time someone ran [clear statistics filer connections](#). As above, these are sessions that did not go through the control plane.

Time of Max data sessions is the date that the above maximum occurred.

Max sessions per data connection shows the most CIFS sessions to simultaneously run over a single TCP connection. This applies to data-plane connections between the ARX and an external client or filer.

Time of Max sessions/connections is the date that the above maximum occurred.

The NFS table contains the following fields:

Current connections counts the current NFS connections to the filer.

Max connections counts the maximum NFS connections to the filer since the last reboot, or since the last time someone ran [clear statistics filer connections](#).

Time of Max connections is the date that the above maximum occurred.

**Guidelines: Detailed
Output for One
Processor**

If you specify a particular filer and processor, the output shows connection statistics for the traffic between them. These statistics are similar to the ones above, but with a more limited scope:

Data Connection limit is the maximum number of connections allowed to this filer from this processor, if any. You can use the [cifs connection-limit](#) command to set the system-wide limit for CIFS connections.

Current data connections is the current number of connections between the processor and the filer. That is, this is the number of connections that are directly related to client connections, and do not come from the control plane (processes on the ACM).

Current control connections counts the current processor/filer connections that terminate at the ACM. The ACM processes do not necessarily relate to any client connections; they are connections from the policy engine or connections that require calculations at the control plane.

Current data sessions shows the number of data sessions that are currently connected to the filer through this processor. Each data connection can hold multiple data sessions, where each session may correspond to a different client. This is the number of sessions that are directly related to client activity, and do not come from the control plane processes on the ACM.

Max sessions per data connection shows the most CIFS sessions to simultaneously run over a single TCP connection. This applies to data-plane connections between the selected processor and filer.

Time of Max sessions/connections is the date that the above maximum occurred.

The NFS table contains a single field:

Current connections counts the current NFS connections between the network processor and the filer.

**Guidelines: Other
Statistics**

You can use the [show filer connections](#) command to examine the current connections to a given filer. For client-side statistics, use [show statistics global server](#). For raw, read/write statistics from the NSM fastpath, use [show statistics namespace ... fastpath](#).

Samples

`bstnA(cfg)# show statistics filer connections`
sums up all connections to all back-end filers. See [Figure 39.9](#) for sample output.

`bstnA(cfg)# show statistics filer fs4 connections`
shows details on the connections and sessions to the fs4 filer. See [Figure 39.10 on page 39-49](#) for sample output.

`bstnA(cfg)# show statistics filer fs4 connections processor 2.1`
shows the connections from a particular network processor. See [Figure 39.11 on page 39-50](#) for sample output.

show statistics global server

Purpose Use the `show statistics global server` command to show the volume of traffic between clients and a global server. The output shows high-level packet counts, and can break the packet counts down to individual RPC calls and/or CIFS commands.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics global server [interface | nfs | cifs]`

`show statistics global server fqdn [interface | nfs | cifs]`

`show statistics global server vip vip [interface | nfs | cifs]`

fqdn (optional, 1-128 characters) is the fully-qualified domain name (for example, “myserver.organization.org”) for a global server. Use [show global server](#) to see a list of global servers. If you omit this, the output includes all global servers.

vip (optional) identifies a single virtual-IP (VIP) address.

interface | nfs | cifs (optional) focuses the output on a single set of statistics. If you omit this option, the output includes all of the statistics that apply to the chosen *fqdn* or *vip*.

interface shows only a table of high-level packet counts.

nfs displays only a table of NFS-procedure calls.

cifs shows only a table of CIFS commands.

Guidelines The output contains one or more tables for each global server. The following fields identify the global server:

Global Server identifies the [global server](#), and

Virtual Server IP is the Virtual IP (VIP) for the [virtual server](#).

Each global server has up to three tables: one for high-level packet counts, one for NFS RPCs, and one for CIFS commands. The NFS and CIFS tables only appear if statistics of the chosen type have been collected. The guidelines below describe each table in more detail.

To clear the counters shown by this command, use [clear statistics global server](#). To examine traffic between the ARX and its filers, use [show statistics namespace ... fastpath](#) for raw read/write statistics or [show statistics filer](#) for NFS/CIFS call counters.

- Guidelines: Interface Statistics** The interface table contains Ingress (incoming) and Egress (outgoing) packet counts for the following packet types:
- Octets are the number of bytes received from clients or transmitted to clients.
 - Unicast Packets,
 - Non Unicast Packets, and
 - Dropped Packets are packet counts. The dropped packets in the Egress column are TCP packets that were dropped by the receiving station; the global server retransmits each of these dropped packets.
- Guidelines: NFS Statistics** The NFS statistics contain one row per NFS-RPC call. These are calls from NFS clients to the chosen global server. Each row contains the following columns:
- NFS RPC is the name of the RPC call.
 - Count is the number of these RPC calls received from NFS clients.
 - % Total shows the percentage of these RPC calls compared to all the other NFS calls.
 - Service Time (uSec) is the average number of microseconds (millionths of one second) from receiving the RPC to sending back a response.
- Guidelines: NFS Errors** If there have been any NFS errors, they appear in a separate table under the NFS traffic statistics. The table contains the following counters:
- FormatError is the number of malformed NFS packets received from clients.
 - NetworkError counts the send and receive failures.
 - ResourceError is the number of times that the ARX software ran out of resources. Contact F5 Support if you see these errors.
 - RPCError counts any errors from the RPC layer.
 - TimeoutError is the number of timeouts waiting for an NFS response.
- Guidelines: CIFS Statistics** The CIFS statistics contain one row per CIFS command. These are commands from CIFS clients to the chosen global server. Each row contains the following columns:
- CIFS Command is the name of the CIFS command.
 - Count is the number of these CIFS commands received from CIFS clients.
 - % Total shows the percentage of these CIFS commands compared to all the other commands.
 - Service Time (uSec) is the average number of microseconds (millionths of one second) from receiving the command to sending back a response.

- Guidelines: CIFS Errors** Any CIFS errors appear in a table under the CIFS statistics, with the following fields:
- **FormatError** is the number of malformed SMB (Server Message Block, an earlier name for CIFS) packets received from clients.
 - **NetworkError** counts the send and receive failures for SMB traffic.
 - **ResourceError** shows the number of times that the ARX software had insufficient resources to complete the transaction. Contact F5 Support if you see these errors.
 - **SignatureError** counts any SMB packets with missing or incorrect signatures. You can use the [cifs filer-signatures](#) command to change the SMB-signing policy for the current namespace.
 - **SMBError** is the number of SMB packets that failed with errors that are not directly related to any of the above errors.
 - **TimeoutError** is the number of timeouts waiting for an SMB response.

Samples `bstnA(cfg)# show statistics global server`
shows statistics for all global servers. See [Figure 39.12 on page 39-53](#) for sample output.

`bstnA(cfg)# show statistics global server ac1.medarch.org`
shows statistics for the global server at “ac1.medarch.org.” See [Figure 39.13 on page 39-56](#) for sample output.

`bstnA(cfg)# show statistics global server vip 192.168.25.12`
shows the statistics for one virtual server. See [Figure 39.14 on page 39-58](#) for sample output.

Managed-Volume Troubleshooting Tools

cancel migration

Purpose The `cancel migration` command stops a file migration that is in progress. You can cancel all migrations in a managed volume or the migration of a single file.

Modes `priv-exec`

Security Role(s) `crypto-officer` or `storage-engineer`

Syntax `cancel migration ns volume vol-path`
`cancel migration file file-name`

ns (1-30 characters) is the namespace where a migration is in process.

vol-path (1-1024 characters) specifies a managed volume.

file-name (1-1024 characters) is the virtual path of a file that is being migrated. This includes the path name for the managed volume itself (for example, the file name for “mydir/myfile.doc” in the “bigvol” volume would be “bigvol/mydir/myfile.doc”).

Default(s) `None`

Guidelines This command removes one file (or all files) from a managed volume’s file-migration queue. You can examine a volume’s migration queue with the [show policy queue](#) command.

If you cancel all migrations in a managed volume, the CLI prompts for confirmation before clearing the queue. Enter **yes** to proceed.

Samples `bstnA# cancel migration medarcv volume /rcrds`
Are you sure you want to cancel all the queued migrates in volume
'/rcrds'? [yes/no] **yes**
`bstnA#`

clears the entire migration queue for the “medarcv~/rcrds” volume.

`bstnA# cancel migration file /claims/2007/masterlist.xml`
removes a single file from its volume’s migration queue.

Related Commands [show policy queue](#)

cancel remove

Purpose The `cancel remove` command stops a share-removal that is in progress.

Modes `priv-exec`

Security Role(s) `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `backup-operator`

Syntax `cancel remove namespace ns volume vol-path share share-name`

ns (1-30 characters) is the namespace from which the share is being removed.

vol-path (1-1024 characters) specifies the namespace volume.

share-name (1-64 characters) is the share that is being removed.

Default(s) None

Guidelines You can remove a share with `remove-share migrate`, `remove-share nomigrate`, `no share`, or `no filer`. The first stage of the share removal is a scan of the filer; this reads all file attributes on the share's back-end directories. During this phase (the longest in the process), you can cancel the share removal. After this phase is over, the CLI does not permit anyone to cancel the operation.

Sample

```
bstnA# cancel remove namespace ns volume /vol share testrun
Storage job cancelled successfully.
bstnA#
        cancels the removal in progress for the “ns~/vol~testrun” share.
```

Related Commands `remove-share migrate`
`remove-share nomigrate`
`share`
`filer`

clear statistics filer

Purpose Use this command to clear the NFS/CIFS traffic statistics for a back-end filer or share.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics filer`
`clear statistics filer ext-filer-name [share share-name]`

ext-filer-name (optional, 1-64 characters) identifies the external filer by its configured name. Use [show external-filer](#) to display all configured external filers. If you omit this argument, the command clears all traffic statistics on the system. This option is not recommended, as it results in incomplete statistics for some forms of `show statistics namespace`.

share-name (optional, 1-64 characters) clears traffic statistics for this specific back-end share. This is the name of the share at the back-end filer, not at the namespace. As above, this option is not recommended; it results in incomplete statistics for some forms of `show statistics namespace`.

Default(s) None

Guidelines The [show statistics filer](#) command shows the NFS and/or CIFS traffic between the ARX's software and its back-end filers. Use this command to clear those traffic counters. This also clears the traffic counters for the various forms of `show statistics namespace ... fastpath`, `show statistics namespace ... request-detail`, `show statistics namespace ... response-detail`, and `show statistics namespace ... summary`.

The CLI prompts for confirmation before clearing the statistics; enter **yes** to proceed.

Sample `bstnA# clear statistics filer das1`
Clear statistics of ALL shares on filer das1.

```
Are you sure? [yes/no] yes
clears the current NFS/CIFS statistics counts for the external filer named "das1."
```

Related Commands [show statistics filer](#)
[show statistics namespace ... fastpath](#)
[show statistics namespace ... request-detail](#)
[show statistics namespace ... response-detail](#)
[show statistics namespace ... summary](#)
[show external-filer](#)

clear statistics metadata

Purpose Managed volumes use *metadata* to track the locations of their files on back-end storage. They store the metadata on an external [metadata share](#), and keep statistics on the usage of that share. Use this command to clear these statistics for the entire system, a specific namespace, or particular managed volume.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics metadata [namespace ns [volume vol]]`

ns (optional, 1-30 characters) identifies a namespace.

vol (optional, 1-1024 characters) is a managed volume.

Default(s) None

Guidelines The [show statistics metadata](#) command shows usage statistics for the metadata shares behind your managed volumes. Use this command to clear these statistical counters for the whole system, one namespace, or one managed volume.
The CLI prompts for confirmation before clearing the statistics; enter **yes** to proceed.

Sample

```
bstnA# clear statistics metadata
Clear metadata performance statistics for all volumes?
Are you sure? [yes/no] yes
clears all metadata-share statistics for the entire ARX.
```

Related Commands [show statistics metadata](#)

clear statistics metalog

Purpose Volume software stores *metalog* data to be used for recovery from failovers (see [redundancy](#)) and crashes. The volume software needs to read and write this metalog data quickly to ensure proper performance; you can use the [show statistics metalog](#) command to monitor the read/write statistics for metalog storage. Use this command to clear these statistics for the entire system or a specific [volume-group](#).

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics metalog [volume-group vol-group-id]`

vol-group-id (optional, 1-255 characters) identifies a volume group. You can use the [show volume-group](#) command to show all volume groups, which volumes are in each of them, and their ID numbers.

Default(s) None

Guidelines The [show statistics metalog](#) command shows usage statistics for the metalog storage behind your managed volumes. These statistics record the latency for metalog reads and writes. Use this command to clear these statistical counters for the whole system or a single volume group.

The CLI prompts for confirmation before clearing the statistics; enter **yes** to proceed.

Sample

```
bstnA# clear statistics metalog volume-group 9
Clear metalog performance statistics for volume group 9?
```

```
Are you sure? [yes/no] yes
clears all metalog statistics for a particular volume group.
```

Related Commands [show statistics metalog](#)

clear statistics migration

Purpose Managed volumes keep statistics on all of their file migrations. Use this command to clear these statistics for an entire namespace or particular managed volume.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics migration namespace [volume]`

namespace (1-30 characters) identifies a namespace.

volume (optional, 1-1024 characters) is a managed volume.

Default(s) None

Guidelines The [show statistics migration](#) command shows file-migration statistics for managed volumes. Use this command to clear the statistical counters for one namespace or managed volume.

The CLI prompts for confirmation before clearing the statistics; enter **yes** to proceed.

Sample `bstnA# clear statistics migration medarcv /rcrds`

Clear data migration statistics? [yes/no] **yes**

clears all file-migration statistics for the “medarcv~/rcrds” volume.

Related Commands [show statistics migration](#)

export-mapping

Purpose Some volumes are configured to constrain each directory to a single back-end share. This constraint simplifies volume backups: you can backup the entire volume directly from the filer-share. Use the `export-mapping` command to create a report that shows the front-end/back-end mapping for these volume configurations.

Modes `priv-exec`

Security Role(s) `network-technician, network-engineer, storage-engineer, or crypto-officer`

Syntax `export-mapping [outputfile outputfile] [nfs | cifs]`

outputfile *outputfile* (optional; 5-128 characters) specifies a prefix for a customized file name (for example, 'jrandom_exp_map.rpt'), as opposed to the default. Use the `show reports` command to display the file in the maintenance directory.

nfs | cifs (optional) narrows the report to a single protocol, NFS or CIFS.

Default(s) `outputfile outputfile - 'export-mapping.rpt.'`

Guidelines The name of the report appears after you issue the command. For long reports, you can use `tail` to follow the report as it is written. Use `show reports export-mapping.rpt` to read the report. You can search through the report with `grep`. To copy or delete it, use the `copy` or `delete` commands. If you want to truncate the report before it finishes, use the `truncate-report` command.

The report is divided into three tables. The first shows all front-end services, the next shows all back-end filers, and the third table maps all front-end shares to a single back-end path. The single back-end path is the *master directory* for the root of the front-end share; by default, all of the front-end share's subdirectories and files go to this back-end path. If it is the only share in the volume, or if policy is not running in the volume, this contains all of the files and directories in the front-end share.

Otherwise, files and directories may be distributed among the volume's shares; use `show server-mapping` for a map of all back-end shares behind each front-end share.

Samples `bstnA# export-mapping`
Generated report: `export-mapping.rpt` on switch `bstnA`
`bstnA# ...`

A sample appears below in [Figure 40.1](#).

`bstnA# export-mapping outputfile nfs_only.rpt nfs`
Generated report: `nfs_only.rpt` on switch `bstnA`
`bstnA# ...`

generates a mapping report for NFS only. See [Figure 40.2 on page 40-11](#) for a sample report.

```

find

Purpose Use the find command to locate one file's back-end filer and path.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax **find host *hostname-or-ip* {nfs| cifs} *share-name* path *path* [verbose]**

hostname-or-ip identifies a virtual server by its external DNS hostname or Virtual-IP address. Use [show virtual service](#) for a list of all virtual servers and their Virtual IP addresses. (To look up DNS names at an external DNS server, you must first identify the server with the [ip name-server](#) command.)

nfs | **cifs** is a required choice, determining the type of share that follows.

share-name (1-4096 characters) is the name of the front-end share, as seen by clients. The [show server-mapping](#) command shows all front-end shares on the ARX, in the left column.

path (1-4096 characters) is the virtual-file path within the front-end share.

verbose (optional) adds the file's NFS filehandles to the output.

find global-server *fqdn* {nfs| cifs} *share-name* path *path* [verbose]

fqdn (1-255 characters) identifies a global server by its fully-qualified domain name (FQDN). Use [show global service](#) for a list of all global servers and their FQDNs.

The remaining options are described above.

find namespace *namespace* path *path* [verbose]

namespace (1-30 characters) identifies the namespace. Use [show namespace](#) for a list of all namespaces.

path (1-4096 characters) is the virtual-file path within the namespace. This is the file path as seen by the client, starting with the volume path.

verbose (optional) adds the file's NFS filehandles to the output.

find wins *wins-name* {nfs| cifs} *share-name* path *path*

wins-name (1-255 characters) identifies a virtual server by its optional [wins-name](#) or one of its optional [wins-alias](#) names.

The remaining options are described above.

Default(s) None.

Guidelines This command finds one file's physical location. To find all file locations behind a namespace, use the `nsck ... report metadata-only` command.

For files in multi-protocol (NFS and CIFS) namespaces, this shows the file's physical location from an NFS point of view and a CIFS point of view.

The output contains several field to map the ARX-volume location of the file to the file's physical location on the filer:

NFS Physical Location is an NFS path to the physical file. This appears in `ip-address:/path-to-file` format.

Managed Volume Path indicates that the *path* is on a **direct** volume, and the physical location is on an ARX **managed-volume** that is standing in as a filer.

CIFS Physical Location is a CIFS path to the physical file. This appears in `//ip-address/path-to-file` format. If this is an NFS-only file in a multi-protocol (CIFS and NFS) volume, a message here indicates that the file has an inconsistent name. You can use the `nsck ... report inconsistencies` command to find all of the volume's inconsistent names.

The **verbose** output shows two NFS filehandles for the file:

Virtual File Handle is the filehandle that the ARX presents to clients.

Physical File Handle is the filehandle that the server gave to the ARX.

The filehandles may be incomplete for the `find namespace` command. Use one of the other versions (such as `find host`) for complete NFS filehandles.

Guidelines: File Tracking The `find` command identifies a file's location now; for a file's location in the past, you can use *file tracking*. File tracking can be useful for finding the correct filer-backup tape for a lost or compromised file.

The file-tracking feature requires some configuration before you can make any file queries. Specifically, a managed volume requires a **snapshot rule** to regularly copy its configuration and metadata to a **file-history archive**. After some copies of metadata have been archived, you can use the `show file-history virtual-service` command to query file locations at different dates.

Samples `bstnA# find namespace wwmed path /acct/index.html`

```
Namespace:          wwmed
Logical path:       /acct/index.html
NFS Physical location: 192.168.25.19:/exports/budget/index.html
                    finds a file in a namespace.
```

`bstnA# find host 192.168.25.14 nfs /claims path /stats/piechart.ppt`

```
Namespace:          insur
Logical path:       /claims/stats/piechart.ppt
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS-QTREE/insurance/stats/piechart.ppt
CIFS Physical location: The file/directory on //192.168.25.21/insurance has an inconsistent name.
```

finds a file behind a virtual server. The virtual server is exporting the file from a multi-protocol namespace, so it shows both NFS and CIFS locations for the file. This file has an inconsistent, NFS-only name.

```
bstnA# find global-server insur.medarch.org nfs /claims path /stats/piechart.ppt
```

```
Namespace:          insur
Logical path:       /claims/stats/piechart.ppt
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS-QTREE/insurance/stats/piechart.ppt
CIFS Physical location: The file/directory on //192.168.25.21/insurance has an inconsistent
name.
```

finds the same file behind its global server.

```
bstnA# find global-server insur.medarch.org cifs CLAIMS path /index.html verbose
```

```
Namespace:          insur
Logical path:       /claims/index.html
NFS Physical location: 192.168.25.21:/vol/vol1/NTFS-QTREE/insurance/index.html
CIFS Physical location: //192.168.25.21/insurance/index.html
```

NFSv3

```
Virtual File Handle (32 bytes):
  0x000000010b00000010000000000400000000000000000000000000000000000000000000000000000000
Physical File Handle (32 bytes):
  0x01c63600f00da62220000000001ef2a0b0727e2104cf00f1400000008be32b00
```

provides a verbose display for another file behind the same global server.

Related Commands [nsck ... report metadata-only](#)

remove service

Purpose Use the `remove service` command to remove a namespace and all other configuration objects that are exclusively dedicated to the namespace (such as global servers, proxy users, and/or NFS access-lists).

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `remove service namespace [timeout seconds] [sync]`

namespace (1-30 characters) identifies the namespace.

seconds (optional, 300-36,000) is a time limit for each component operation in this service removal, in seconds.

sync (optional) shows the operation's progress at the command line. With this option, the CLI prompt does not return until all components have been removed.

Default(s) None.

Guidelines The CLI prompts for confirmation before removing any configuration objects or metadata; enter `yes` to proceed.

This removes the following objects from the system:

- metadata behind all of the namespace's volumes
- all objects created for CIFS browsing
- all front-end exports that reference the namespace's volumes
- all global and virtual servers that are dedicated to this namespace
- all policy (rules, snapshots, share farms, and filesets)
- all shares and metadata shares
- any NFS access lists that are exclusively devoted to the namespace
- any external filers that are exclusively devoted to the namespace

By default, this command generates a report to show all of the actions it takes to remove the volume(s), in order. The CLI shows the report name after you issue the command, and then returns. You can enter CLI commands as the namespace software removes the objects in the background. Use `tail` to follow the report as it is written. Use `show reports file-name` to read the report. You can search through the report with `grep`. To copy or delete it, use the `copy` or `delete` commands. Use the `sync` option to send the status to the command line instead; the command does not generate a report if you use the `sync` option.

If you remove a `cifs` service with any `dynamic-dns` names, you must remove all of the Dynamic DNS names (with `no dynamic-dns`) before you run this command.

Use `remove namespace` to remove a namespace or volume without affecting any global servers, NFS-access-control lists, or external filers. To remove only the policy objects from the namespace or a single volume, use `remove namespace ... policy-only`. The `remove namespace ... volume ... exports-only` command finds all of a volumes front-end exports and removes them. To remove a share from a volume, use `remove-share migrate` or `remove-share nomigrate`.

Sample bstnA# `remove service medco`

Remove service 'medco'? [yes/no] **yes**

Scheduling report: `remService_medco_201002240751.rpt`

removes all configuration objects associated with the “medco” namespace.

Related Commands [remove namespace](#)
[remove namespace ... policy-only](#)
[remove namespace ... volume ... exports-only](#)
[remove-share migrate](#)
[remove-share nomigrate](#)

remove-share migrate

Purpose Use the `remove-share migrate` command to remove a share from a namespace volume and move all of its files to another share or share farm in the same volume. The volume's clients are unaffected by this share removal.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `remove-share migrate namespace volume share dest [close-file [exclude fileset]] [async]`

namespace (1-30 characters) identifies the namespace.

volume (1-1024 characters) is the name of the volume.

share (1-64 characters) is share being removed.

dest (1-64 characters) is the new destination share or share farm for files and master directories.

close-file (optional) causes the operation to close all files open by CIFS clients in order to migrate them. If you omit this option, files opened by CIFS clients cannot migrate off of the selected *share*. This would leave files stranded on the share and cause the share removal to fail.

exclude fileset (optional if you choose **close-file**, 1-64 characters) is a fileset to exclude from automatic closure. If a file in this fileset is open through CIFS, the rule places it on a retry queue instead of automatically closing it. If such a file remains open for the duration of the share removal, it never migrates off of the share and the share-removal fails.

async (optional if you specify a *dest*) makes this command return immediately, rather than waiting for the share removal to finish.

Default(s) None.

Guidelines This command does not apply to direct volumes (see [direct](#)); only metadata-based managed volumes.

Before removing the share, resolve all dependencies on the share. You can use [show policy](#) to verify that no policy rules reference the share.

This is not recommended in a volume that supports snapshots. In those volumes, you should use a [place-rule](#) to drain the share first, wait until all retained snapshots have "aged out," and then run this command or [remove-share nomigrate](#).

The back-end share must be online for this command to succeed. If the back-end share is offline, you can use [remove-share offline](#) to remove the share from the namespace.

You have the option to configure the share to retain copies of its migrated files, in case you need to recover them later: use [migrate retain-files](#) on the share before you run this command.

Clients are not impacted by the `remove-share` command. All files that migrate to the new back-end share remain in the same volume and namespace, so their file associations remain intact. Front-end clients see no change.

Guidelines: Share Removal in Multi-Protocol Namespaces A directory in a multi-protocol (NFS and CIFS) share cannot migrate if it has an NFS-only name; the volume cannot access the directory through CIFS to replicate its CIFS attributes. You can access the volume through an NFS export and rename the NFS-only directory, or you can temporarily turn off [strict-attribute-consistency](#) at the *dest* share(s).

◆ **Note**

The migration may be slower in a multi-protocol volume. If it's possible for a legitimate directory name to collide with a filer-generated name (like "DIR~1") at one of the filers, the volume probes the target filer(s) for conflicting names.

Guidelines: No Migration Needed for Replica-Snap Shares A volume uses the snapshots on a [replica-snap](#) share and ignores all other files and directories. This type of share does not have any files or directories to migrate, so the *dest* share, **close-file**, and **exclude** options are all ignored.

Guidelines: Reports This command creates two reports:

- `drain_share_rule_for_share_share-name_time.rpt`, and
- `remove.job-id.share-name.share-id.rpt`

Use [show reports](#) to view either of these reports.

Guidelines: Directory Tree Remains After Share Removal When you remove a share from a namespace, the share's empty directory tree remains on the back-end filer. After the removal is complete, you can access the filer directly and remove the empty directory tree.

Sample

```
prtlnDA# remove-share migrate nemed /vol144 rxbills globalmedco
close-file
```

removes the '/vol144~rxbills' share from the 'nemed' namespace, and migrates its files and any primary copies of its directories to the 'globalmedco' share farm. It also closes any files that are currently opened by CIFS clients, so that they will be drained from the share, too.

Related Commands [strict-attribute-consistency](#)
[remove-share nomigrate](#)
[remove-share offline](#)
no share
[wait-for remove](#)

remove-share nomigrate

Purpose Use the `remove-share nomigrate` command to remove a share from a namespace without migrating any of its files. This causes all of the share's files (if there are any) to be removed from the volume.

Modes `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `remove-share nomigrate namespace volume share [dest [async]]`

namespace (1 - 30 characters) is the name of the namespace.

volume (1 - 1024 characters) is the name of the volume.

share (1 - 64 characters) is the name of the share.

dest (not allowed for [replica-snap](#) shares, but required for all other share types; 1 - 64 characters) is the new destination share or share farm where the original share's primary copies of directories (if identified) are to be migrated. Use [show global-config namespace](#) for a list of shares and share farms in the namespace.

async (optional if you specify a *dest*) makes this command return immediately, rather than waiting for the share removal to finish.

Default(s) None.

Guidelines This command does not apply to direct volumes (see [direct](#)); only metadata-based managed volumes.

Before removing the share, resolve all dependencies on the share. You can use [show policy](#) to verify that no policy rules reference the share.

This command deletes all of the share's files from the volume's metadata; from the client's perspective, these files disappear. Use this only for shares that have import failures or must keep their files after being removed from the namespace. For a share that is unreachable, use [remove-share offline](#) instead. To migrate the files to another share in the same managed volume, use [remove-share migrate](#).

**Guidelines: Migrating
Master Directories**

If the share contains any master directories in the volume (that is, the first-imported instance of a directory), they are copied to the *dest* share or share farm. This may fail if the remove process encounters any of the following issues:

- A master directory in a multi-protocol (NFS and CIFS) share cannot migrate if it has an NFS-only name; the volume cannot access the directory through CIFS to replicate its CIFS attributes. You can access the volume through an NFS export and rename the NFS-only directory, or you can temporarily turn off [strict-attribute-consistency](#) at the *dest* share(s).
- A master directory may not be able to migrate to a *dest* that supports CIFS if the destination filer is very low on free space. The CIFS ACL(s) from the master directory could exceed the free space on the destination. You can resolve this issue by choosing a *dest* with more free space behind it, increasing disk space on the destination filer(s), or using a [place-rule](#) (with a [source share](#)) to migrate files from the *dest* share to an emptier share in the same managed volume.

A volume uses the snapshots on a [replica-snap](#) share and ignores all other files and directories. This type of share does not have any master directories to migrate, so a *dest* share is not required.

Guidelines: Report

This command creates a report, “`remove.job-id.share-name.share-id.rpt.`” Use [show reports](#) to view its contents.

Sample

```
bstnA# remove-share nomigrate nemed /vol133 oldScripts globalmedco  
removes the '/vol133~oldScripts' share from the 'nemed' namespace and moves  
any master directories on that share to the 'globalmedco' share.
```

Related Commands

[remove-share migrate](#)
[remove-share offline](#)
[no share](#)
[nsck ... destage](#)
[strict-attribute-consistency](#)
[wait-for remove](#)

remove-share offline

Purpose	Use the <code>remove-share offline</code> command to remove an offline, unreachable, or otherwise defunct back-end share from a namespace.
Modes	priv-exec
Security Role(s)	storage-engineer or crypto-officer
Syntax	<code>remove-share offline namespace volume share dest [async]</code>

namespace (1 - 30 characters) is the name of the namespace.

volume (1 - 1024 characters) is the name of the volume.

share (1 - 64 characters) is the name of the share.

dest (1 - 64 characters) is the new destination share or share farm where the original share's master directories (if any) are to be migrated. A *master directory* is the first-imported instance of a directory in the managed volume. Use [show global-config namespace](#) for a list of shares and share farms in the namespace.

async (optional) makes this command return immediately, rather than waiting for the share removal to finish.

◆ Important

*This operation migrates any master directories from the defunct share to the **dest**. Because the share is unreachable, this operation cannot probe those directories to find their file attributes and/or ACLs. The file attributes for the master directories are therefore set to zero at the **dest**.*

Default(s)	None.
Guidelines	<p>This command does not apply to direct volumes (see direct); only metadata-based managed volumes.</p> <p>Only use this command for a back-end share that is unreachable. If the share is still reachable, use remove-share migrate or remove-share nomigrate instead.</p> <p>Before removing the share, resolve all dependencies on the share. You can use show policy to verify that no policy rules reference the share.</p> <p>This command deletes all of the share's files from the volume's metadata; from the client's perspective, these files disappear. Given that the back-end filer was unreachable, those files were already inaccessible to clients.</p> <p>This command creates a report, "remove.job-id.share-name.share-id.rpt." Use show reports to view its contents.</p> <p>As mentioned above, this command migrates all master directories with 0 (zero) file attributes. Look in the remove report to find these directories: in the section below Prepare Start Time, look for [AR] next to each affected directory. You can access the volume through its VIP to manually reset the attributes of these directories.</p>

Sample `bstnA# remove-share offline nemed /vol133 rxpresc globalmedco`
removes the '/vol133~rxpresc' share from the 'nemed' namespace. If the share had any master directories, this command recreates them on the 'globalmedco' share with zeros for their file attributes and/or ACLs.

show policy history

Purpose Use the `show policy history` command to view the policy events that have occurred in a volume, or the detailed events for a specific rule or share farm.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, and operator

Syntax `show policy history namespace namespace volume volume [rule rule-name]`

namespace (1-30 characters) is the namespace.

volume (1-1024 characters) identifies the volume.

rule-name (optional, 1-1024 characters) narrows the scope to one rule or share farm in the volume. This shows detailed history for the rule or share farm.

Guidelines The output shows one row per policy event, with the date and time for each. The output contains up to 100 events.

The `show policy` command shows all namespace policies. Use `show policy filesets` to show all filesets, and use `show schedule` to show all schedules. The `show policy queue` command shows all files currently waiting to be migrated, if any.

Samples `bstnA# show policy history namespace insur volume /claims`
shows the policy history for the “insur~/claims” volume. See [Figure 40.3 on page 40-23](#) for sample output.

`prt1ndA# show policy history namespace nemed volume /acctShdw rule farm1`
on a different switch, shows policy history for a share farm. See [Figure 40.4 on page 40-24](#) for sample output.

show policy queue

Purpose Use the `show policy queue` command to see which files (if any) are currently queued for migration.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, and operator

Syntax `show policy queue namespace namespace volume volume [auto-close]`

namespace (1-30 characters) is the namespace.

volume (1-1024 characters) identifies the volume.

auto-close (optional) limits the output to files that have been auto-closed. (A file-placement rule can auto-close any file that is already opened through CIFS, and can hold it closed until the file is migrated. The [migrate close-file](#) command enables this feature.)

Guidelines This command is useful for diagnosing migration issues in a particular volume. It shows all the files that are currently waiting to be migrated, three lines per file. These lines contain the following fields:

File, on the top line, is the file being migrated. This is shown from the client's perspective.

Rule is the name of the rule or share farm that is migrating the file.

Target is the name of the target share or share farm. This is the name of the share from the namespace configuration; use the [show global-config namespace](#) command to show all shares in a namespace.

Status is the third line. This explains the current status of the file migration.

The output is typically an empty table, as migrations occur very quickly.

If the queue is very full because migrations are repeatedly failing, you can use the [policy migrate-delay](#) command to stop the policy engine from infinitely retrying its migrations. This causes the policy engine to remove all old entries from the queue. You can also use [policy migrate-retry-delay](#) to change the time between migration retries.

The [cancel migration](#) command clears the queue.

Sample `bstnA# show policy queue namespace medarcv volume /rcrds`
shows the policy queue for the "medarcv~/rcrds" volume. See [Figure 40.5](#) for sample output.

```

show statistics filer

Purpose Use the `show statistics filer` command to show the numbers of NFS RPCs and CIFS SMB commands from various software subsystems to one or more filers.

Mode (any)

Security Role(s) `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

Syntax `show statistics filer [nfs | cifs] [summary | request-detail | response-detail]`

`show statistics filer ext-filer-name [share {shr | all}] [nfs | cifs] [summary | request-detail | response-detail]`

nfs | **cifs** (optional) limits the output to NFS statistics or CIFS statistics.

summary | **request-detail** | **response-detail** is an optional choice, where

summary shows the counts of each NFS and/or CIFS request, the counts of the corresponding responses, and the average round-trip times (RTTs). This is the default output if you select none of these options.

request-detail shows the counts of each NFS and/or CIFS request from each software component.

response-detail shows average RTT for each NFS and/or CIFS response to each software component.

ext-filer-name (optional, 1-64 characters) identifies the external filer by its configured name. Use [show external-filer](#) to display all configured external filers.

shr | **all** is a required choice if you use the optional **share** keyword:

shr (1-64 characters) focuses on traffic to this specific back-end share. This is the name of the share at the back-end filer, not at the namespace.

all shows all shares on the filer. This creates a separate table for each share; if you omit the **share all** option, the output contains a single table showing the sums of all shares.

Guidelines The output from the simplest syntax, `show statistics filer`, shows one or two tables of statistics per [external-filer](#): a table of NFS-traffic statistics and/or a table for CIFS traffic. Each row of the NFS table shows the total packets for a particular NFS RPC. Each row in the CIFS table shows the total packets for a given CIFS SMB command. Each row also displays the average RTT for the RPC or SMB.

To clear the counters shown by this command, use [clear statistics filer](#). For client-side statistics, use [show statistics global server](#). To sort these statistics by namespace or volume, use [show statistics namespace ... summary](#), [show statistics namespace ... request-detail](#), [show statistics namespace ... response-detail](#), or [show statistics namespace ... fastpath](#).

Guidelines: Output This output shows a separate set of tables for every selected back-end filer:

Filer is the name of the external filer. As mentioned above, you can use the [show external-filer *filer-name*](#) command to see the IP address and/or SPN for *filer-name*.

All shares in *filer* appears if you did not use the **share** keyword to specify a single share. This indicates that the statistics are at the filer level; they are the sum of the statistics for all of the filers' imported shares. If you select a particular share, the following fields appear instead:

- NFS Export or
- CIFS Share is the name of the export or share at the filer. Both names appear if this is used as a multi-protocol share.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone uses the [clear statistics filer](#) command or [reloads](#) the chassis.

Guidelines: request-detail and response-detail Output The **request-detail** flag focuses on request counts. This option breaks the request-count statistics down into the software subsystems that sent them:

- Data Plane is *fastpath* traffic through the network software. These packets are not handled by any volume-group software on the Control Plane.
- Ctrl Plane (short for Control Plane) is traffic that passes through the volume-group software for further processing.
- Policy shows the traffic that is initiated by the policy engine, such as migrations and shadow copies.
- Probe is the statistics from the health-checking subsystem in the namespace software. This subsystem sends periodic health-check probes to every back-end share that is connected to an ARX volume.

The **response-detail** flag focuses on average RTTs. This option also breaks the statistics down into the software subsystems that sent the RPCs and/or SMBs.

Guidelines: NFS Errors NFS errors appear in a separate table under the NFS RPC statistics. The table contains the following counters:

- FormatError is the number of malformed NFS packets received from the filer(s).
- NetworkError counts the send and receive failures.
- ResourceError is the number of times that the ARX software ran out of resources. Contact F5 Support if you see these errors.
- RPCError counts any errors from the RPC layer.
- TimeoutError is the number of timeouts waiting for an NFS response.

- Guidelines: CIFS Errors** Any CIFS errors appear in a similar table under the CIFS SMBs, with the following fields:
- **FormatError** is the number of malformed SMB (CIFS) packets received from the filer(s).
 - **NetworkError** counts the send and receive failures for SMB traffic.
 - **ResourceError** shows the number of times that the ARX software had insufficient resources to complete the transaction. Contact F5 Support if you see these errors.
 - **SignatureError** counts any SMB packets with missing or incorrect signatures. You can use the [cifs filer-signatures](#) command to change the SMB-signing policy for the current namespace.
 - **SMBError** is the number of SMB packets that failed with errors that are not directly related to any of the above errors.
 - **TimeoutError** is the number of timeouts waiting for an SMB response.

Samples `stkbrgA(cfg)# show statistics filer`
summarizes all requests and responses to all back-end filers. See [Figure 40.6](#) for sample output.

`canbyA(cfg)# show statistics filer nfs reponse-detail`
shows the response times for NFS RPCs to the filers behind “canbyA.” See [Figure 40.7 on page 40-34](#) for sample output.

show statistics metadata

Purpose Each managed volume stores *metadata* about the files that it keeps on its back-end shares. This metadata is stored on an external [metadata share](#). The latency between the managed-volume software and this external metadata share must be small or the volume's performance suffers. Use the `show statistics metadata` command to measure the latency between namespace processes and their metadata storage.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics metadata [namespace name [volume vol]]`

name (1-30 characters) specifies one namespace. You can use [show namespace](#) to get a list of all namespaces.

vol (optional; 1-1024 characters) specifies one managed volume.

Default(s) None

Guidelines Use this command to measure the performance of managed-volume software with respect to metadata storage. The output contains one table per volume, with each of the following fields:

Namespace,

Volume, and

Location identify a specific metadata share. The name of the back-end filer is its [external-filer](#) name as defined on the ARX; you can use [show external-filer](#) to find its IP address, SPN, and configuration information.

Last Reset Time shows the last time the volume software started or someone cleared these statistics with [clear statistics metadata](#).

The next group of fields describe statistics for metadata-read operations:

- Read Operations counts the number of reads since the above last-reset time.
- Read Response Time is the average response time for the read operations,
- Read Bytes is the total bytes since the Last Reset Time,
- Read Rate shows the running average in Megabytes per second,
- Read Errors counts the total read errors since the volume group started,
- Read Operations in Progress is the number of read operations currently underway, and
- Last Read Operation is a date stamp for the most-recent read operation.

The above statistics are then repeated for all write operations.

Sample `bstnA# show statistics metadata`

measures and displays the latency between all volumes and their metadata storage. See [Figure 40.8 on page 40-38](#) for sample output.

show statistics metalog

Purpose Namespace software records important information in its *metalog*, possibly to be used later for a failure recovery. To ensure proper volume performance, this latency should be low. Use the `show statistics metalog` command to measure the latency between namespace processes and their metalog storage.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics metalog [volume-group id]`

id (optional, 1-255) identifies a particular volume group. If you omit the number, this command displays all volume groups.

Default(s) None

Guidelines To ensure proper volume performance, this latency and the latency to the backup peer (measurable with `show redundancy metalog`) should be as low as possible. Use this command to measure the performance of namespace software with respect to metalog storage. The output contains one table per volume group, with each of the following fields:

Last Reset Time shows the last time the volume-group software started, or the last time someone used `clear statistics metalog` on the volume group.

Read Operations counts the number of reads since the above time.

Read Response Time is the average response time for the read operations,

Read Bytes is the total bytes read since the **Last Reset Time**,

Read Rate shows the running average round-trip time for read operations, in Megabytes per second,

Read Errors counts the total read errors since the volume group started,

Read Operations in Progress is the number of read operations currently underway, and

Last Read Operation is a date stamp for the most-recent read operation.

The above statistics are then repeated for all write operations.

The ARX-1500 and ARX-2500 store their metalog data on their internal disks. On those platforms, you can use the `show metalog usage` command to see the metalog-usage statistics.

The ARX-VE stores its metalog data on an external data store. On the ARX-VE, you can use the `probe metalog latency` command to test the latency between the ARX and this external storage.

The `show redundancy metalog` command shows the latency for resilvering (copying) metalog data to the backup peer. If that latency is too high, slower volume processing may be noticeable by volume clients.

Samples `bstnA# show statistics metalog`

measures and displays the latency between all volume groups and their metalog storage. See [Figure 40.9 on page 40-42](#) for sample output.

`bstnA# show statistics metalog volume-group 1`

focuses on volume group 1. See [Figure 40.10 on page 40-44](#) for sample output.

show statistics migration

Purpose	Use the <code>show statistics migration</code> command to show the file-migration activity on the current ARX.
Mode	(any)
Security Role(s)	crypto-officer, storage-engineer, network-engineer, network-technician, or operator
Syntax	<pre>show statistics migration [namespace ns [volume vol]] show statistics migration activity [namespace ns [volume vol]] show statistics migration history [namespace ns [volume vol]]</pre> <p><i>ns</i> (optional; 1-30 characters) specifies one namespace.</p> <p><i>vol</i> (optional; 1-1024 characters) specifies one managed volume.</p> <p>activity (optional) shows all migrations that are currently in progress for each of the chosen volumes.</p> <p>history (optional) shows the last 100 migrations that occurred in each of the chosen volumes.</p>
Guidelines	<p>The policy engine enforces a managed volume's rules by migrating files from one back-end filer to another. A place-rule causes file migrations, as does the auto-migrate command in a share-farm. Use this command to view in-flight migrations, migration history, and some migration-related statistics.</p> <p>The output is divided into namespaces, volume groups, and then volumes. All volumes appear in the output, whether or not they have any migration statistics.</p> <p>Namespace identifies a namespace.</p> <p>Volume Group is one volume-group in the above namespace.</p> <p>Volume shows one volume in the above volume group.</p> <p>Below each volume are the statistics requested, or configuration data if you did not select activity or history. A volume without any policy associated with it does not have anything below its name.</p>
Guidelines: Default Output	<p>The summary view contains a table of namespace-migration statistics followed by a table of per-volume statistics.</p> <p>Last Reset Time is the last time (in UTC, not local time) that someone ran the clear statistics migration command or rebooted the chassis.</p> <p>Files Migrated is the total files migrated in the namespace.</p> <p>Failed Migrations shows how many migrations failed.</p> <p>Migration Time is the time required to migrate all of the Files Migrated.</p> <p>Data Migrated counts the total size of files successfully migrated.</p> <p>Active Migration Count is the number of migrations that are currently underway. You can see the details of these migrations by re-running this command with the activity keyword.</p> <p>Average Data Rate is the average rate of transfer for all migrations behind the namespace.</p>

- Guidelines: Default Output (Cont.)** Largest File Size, Smallest File Size and Average File Size are high, low, and average samplings of the files migrated in the namespace.
- Guidelines: Activity View** If you use the `activity` option, the output contains a **Current Migration Activity** table for each volume instead of the migration statistics. This table lists the files that the policy engine is currently migrating, one file per row.
- Guidelines: History View** The history option shows two tables per volume with the most-recent migrations (up to 100 total):
- Migration History Failure Activity** shows each failed migration, one per row. Each row contains four fields.
- Timestamp** shows when the migration failed (in UTC, not local time),
 - Source** is the back-end filer and path where the file started.
 - Destination** is the back-end filer and path where the policy engine attempted (and failed) to migrate the file.
 - Reason** is the reason for the failure.
- Migration History Success Activity** lists all successful migrations. Each row contains the following fields.
- Timestamp** shows when the migration occurred (in UTC, not local time),
 - Source** is the back-end filer and path where the file started.
 - Destination** is the back-end filer and path where the policy engine migrated the file.
- Samples**
- `bstnA(cfg)# show statistics migration`
shows high-level migration statistics for the “bstnA” chassis. See [Figure 40.11](#) for sample output.
- `bstnA(cfg)# show statistics migration history namespace medarcv`
shows the detailed migration history for the “medarcv” namespace. See [Figure 40.12 on page 40-48](#) for sample output.

show statistics namespace ... fastpath

Purpose Use the `show statistics namespace ... fastpath` command to show raw read/write statistics between a namespace and its back-end shares.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics namespace ns [volume vol [share {shr | all}]] fastpath`

ns (1-30 characters) identifies the namespace.

vol (optional; 1-1024 characters) specifies one volume in the namespace.

shr | **all** is a required choice if you use the optional **share** keyword:

shr (1-64 characters) specifies one share in the volume.

all shows all shares in the volume. This creates a separate table for each share; if you omit the **share all** option, the output contains a single table showing the sums of all shares.

fastpath specifies that you want the raw statistics for the chosen volumes, as opposed to NFS and/or CIFS statistics (see [show statistics filer](#)). These statistics are kept by the fastpath processes on the NSM (or Data Plane).

Guidelines This command focuses on the fastpath, or data-plane, communication with back-end filers. These are raw byte counts for reads and writes, and the average packet latency. To see the counts of various CIFS and/or NFS requests to the namespace's filers, you can use the [show statistics namespace ... request-detail](#) command. To see the round-trip times (RTTs) for all of these requests, you can use [show statistics namespace ... response-detail](#). For a summary, showing request and response counts together with RTTs, use [show statistics namespace ... summary](#). The output of all three commands includes the counts of various errors. As with this command, you can see these statistics summarized for an entire namespace, focused on a single volume, or focused on one share.

Guidelines: Output This output shows the raw byte counts and throughput between the chosen namespace, volume, or share and its back-end filer(s). Each volume has a separate table of statistics with the following fields:

Namespace and

Volume identify the volume.

All shares in **volume** appears if you did not use the **share** keyword to specify a single share. This indicates that the statistics are at a volume level; they are the sum of the fastpath (data-plane) statistics for all of the volume's shares. If you select a particular share, the following fields appear instead:

- Share identifies the share, as it is named in the ARX configuration. The [show global-config namespace name](#) command shows the share names in the ARX configuration.

**Guidelines: Output
(Cont.)**

- Filer is the name of the external filer that hosts the share. Again, this is the name of the filer in the ARX configuration; you can use the [show external-filer *filer-name*](#) command to see the IP address and/or SPN for *filer-name*.
- NFS Export or
- CIFS Share is the name of the export or share at the filer. Both names appear if this is used as a multi-protocol share.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone [reloads](#) the chassis or uses [clear statistics filer](#) on the share.

Bytes Read,

Read Calls,

Bytes Written, and

Write Calls are all measured since the share was last enabled. Use the [enable \(gbl-ns-vol-shr\)](#) command to enable a namespace share.

Other Calls is the sum of other Remote Procedure Calls (RPCs) including statistics operations and file opens.

All Calls is the sum of reads, writes, and other RPCs.

Average Latency is the average packet-round-trip time between the ARX and the share.

**Guidelines: Clearing
Statistics**

You can use the [clear statistics filer](#) command to clear the statistics from all variations of `show statistics namespace`. If you use that command to clear the statistics from one share in a volume but not another, the volume-level statistics in this command are inconsistent; one share may have statistics for 2 months and the other share may have statistics for only 5 minutes. To confirm that the volume has consistent statistics, run this command on each of the volume's shares and verify that the **Reset...** field has the same date and time for each of them.

Samples

`bstnA> show statistics namespace wwmed fastpath`
shows fastpath statistics for the namespace, "wwmed." See [Figure 40.13 on page 40-51](#) for sample output.

`bstnA> show statistics namespace medarcv volume /rcrds fastpath`
shows statistics for the volume, "medarcv~/rcrds." See [Figure 40.14 on page 40-51](#) for sample output.

Other calls:          180  
All calls:            271  
Average latency:     175900 uSec
```

show statistics namespace ... request-detail

Purpose Use the `show statistics namespace ... request-detail` command to show request counts between a namespace and its back-end shares. The request counts are broken down by request type: the output shows separate counters for each CIFS (SMB) procedure call and/or NFS RPC.

Mode (any)

Security Role(s) `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

Syntax `show statistics namespace ns [volume vol [share {shr | all}]] request-detail`

ns (1-30 characters) identifies the namespace.

vol (optional; 1-1024 characters) specifies one volume in the namespace.

shr | **all** is a required choice if you use the optional **share** keyword:

shr (1-64 characters) specifies one share in the volume.

all shows all shares in the volume. This creates a separate table for each share; if you omit the **share all** option, the output contains a single table showing the sums of all shares.

request-detail causes the output to focus on request counts from ARX software to its back-end shares. This also shows error counts.

Guidelines This command counts the requests from the chosen namespace, volume or share to its back-end filers. These are cross-referenced by request format and by the software component that made the request. To see the round-trip times (RTTs) for all of these requests, you can use [show statistics namespace ... response-detail](#). For a summary, showing request and response counts together with RTTs, use [show statistics namespace ... summary](#). The output of all three commands includes the counts of various errors. To see the raw read/write statistics for the same namespace, volume, or share, you can use the [show statistics namespace ... fastpath](#) command. As with this command, you can see these statistics summarized for an entire namespace, focused on a single volume, or focused on one share.

Guidelines: Output The output shows the counts of specific request types from each component of namespace software. Each selected volume has a separate table of statistics with the following fields:

Namespace and

Volume identify the volume.

All shares in volume appears if you did not use the **share** keyword to specify a single share. This indicates that the statistics are at a volume level; they are the sum of the statistics for all of the volume's shares. If you select a particular share, the following fields appear instead:

- Share identifies the share, as it is named in the ARX configuration. The [show global-config namespace name](#) command shows the share names in the ARX configuration.

**Guidelines: Output
(Cont.)**

- **Filer** is the name of the external filer that hosts the share. Again, this is the name of the filer in the ARX configuration; you can use the [show external-filer *filer-name*](#) command to see the IP address and/or SPN for *filer-name*.
- **NFS Export** or
- **CIFS Share** is the name of the export or share at the filer. Both names appear if this is used as a multi-protocol share.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone [reloads](#) the chassis or uses [clear statistics filer](#) on the share.

The remainder of the output are up to four tables of request counters: NFS RPCs, NFS Errors, CIFS SMBs, and/or CIFS Errors. These tables all have request (or error) types with four columns:

- **Data Plane** is *fastpath* traffic from the network software.
- **Ctrl Plane** (short for Control Plane) is traffic from volume-group software.
- **Policy** shows the requests from the policy engine, which performs migrations, shadow copies, and other policy-related functions.
- **Probe** is the requests from the health-checking subsystem in the namespace software. This subsystem sends periodic requests to every back-end share that is connected to an ARX volume.

**Guidelines: NFS RPC
Table**

NFS RPC - Each row of the NFS table shows the total counts for a particular NFS-RPC request. Each column shows the source of the RPC request, as described above.

**Guidelines: NFS Error
Table**

Errors appear in a separate table under the NFS statistics. The table contains the following counters, with the same columns as the RPC table:

- **FormatError** is the number of malformed NFS packets received from the filer(s).
- **NetworkError** counts the send and receive failures.
- **ResourceError** is the number of times that the ARX software ran out of resources. Contact F5 Support if you see these errors.
- **RPCError** counts any errors from the RPC layer.
- **TimeoutError** is the number of timeouts waiting for an NFS response.

**Guidelines: CIFS SMB
Table**

CIFS SMB - Each row in the CIFS table shows the total counts for a given CIFS (SMB) request. This has the same columns as the NFS tables above.

Guidelines: CIFS Error Table

Errors appear in a similar table under the CIFS statistics, with the following fields:

- **FormatError** is the number of malformed SMB (CIFS) packets received from the filer(s).
- **NetworkError** counts the send and receive failures for SMB traffic.
- **ResourceError** shows the number of times that the ARX software had insufficient resources to complete the transaction. Contact F5 Support if you see these errors.
- **SignatureError** counts any SMB packets with missing or incorrect signatures. You can use the [cifs filer-signatures](#) command to change the SMB-signing policy for the current namespace.
- **SMBError** is the number of SMB packets that failed with errors that are not directly related to any of the above errors.
- **TimeoutError** is the number of timeouts waiting for an SMB response.

Guidelines: Clearing Statistics

You can use the [clear statistics filer](#) command to clear the statistics from all variations of `show statistics namespace`. If you use that command to clear the statistics from one share in a volume but not another, the volume-level statistics in this command are inconsistent; one share may have statistics for 2 months and the other share may have statistics for only 5 minutes. To confirm that the volume has consistent statistics, run this command on each of the volume's shares and verify that the `Reset...` field has the same date and time for each of them.

Samples

```
stoweA> show statistics namespace lodges request-detail
```

shows request statistics for the “lodges” namespace. See [Figure 40.15 on page 40-54](#) for sample output.

```
bstnA> show statistics namespace wwmed volume /acct request-detail
```

shows request statistics for the “wwmed~/acct” volume. See [Figure 40.16 on page 40-56](#) for sample output.

```
bstnA> show statistics namespace wwmed volume /acct share all request-detail
```

shows request statistics for the same volume, but for each individual share in the volume instead of the summed statistics. See [Figure 40.17 on page 40-57](#) for sample output.

show statistics namespace ... response-detail

Purpose Use the `show statistics namespace ... response-detail` command to show latency statistics between a namespace and its back-end shares.

Mode (any)

Security Role(s) `crypto-officer`, `storage-engineer`, `network-engineer`, `network-technician`, or `operator`

Syntax `show statistics namespace ns [volume vol [share {shr | all}]] response-detail`

ns (1-30 characters) identifies the namespace.

vol (optional; 1-1024 characters) specifies one volume in the namespace.

shr | **all** is a required choice if you use the optional **share** keyword:

shr (1-64 characters) specifies one share in the volume.

all shows all shares in the volume. This creates a separate table for each share; if you omit the **share all** option, the output contains a single table showing the sums of all shares.

response-detail shows the round-trip times between various ARX software and back-end shares. This also shows error counts.

Guidelines This command displays round-trip times (RTTs) between the chosen namespace, volume or share and its back-end filers. These are cross-referenced by request format and by the software component that made the request. To see the counts for all of these requests, you can use [show statistics namespace ... request-detail](#). For a summary, showing request and response counts together with RTTs, use [show statistics namespace ... summary](#). The output of all three commands includes the counts of various errors. To see the raw read/write statistics for the same namespace, volume, or share, you can use the [show statistics namespace ... fastpath](#) command. As with this command, you can see these statistics summarized for an entire namespace, focused on a single volume, or focused on one share.

Guidelines: Output The output shows the round-trip times (RTTs) for specific requests from each component of namespace software. Each selected volume has a separate table of RTT statistics with the following fields:

Namespace and

Volume identify the volume.

All shares in volume appears if you did not use the **share** keyword to specify a single share. This indicates that the statistics are at a volume level; they are the sum of the RTT statistics for all of the volume's shares. If you select a particular share, the following fields appear instead:

- Share identifies the share, as it is named in the ARX configuration. The [show global-config namespace name](#) command shows the share names in the ARX configuration.

**Guidelines: Output
(Cont.)**

- Filer is the name of the external filer that hosts the share. Again, this is the name of the filer in the ARX configuration; you can use the [show external-filer *filer-name*](#) command to see the IP address and/or SPN for *filer-name*.
- NFS Export or
- CIFS Share is the name of the export or share at the filer. Both names appear if this is used as a multi-protocol share.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone [reloads](#) the chassis or uses [clear statistics filer](#) on the share.

The remainder of the output are up to four tables: average times for NFS RPCs, counts of NFS Errors, times for CIFS SMBs, and/or counts of CIFS Errors. Each table shows request (or error) types with four columns:

- **Data Plane** is *fastpath* traffic from the network software.
- **Ctrl Plane** (short for Control Plane) is traffic from the volume-group software.
- **Policy** shows the RTT times from the policy engine, which performs migrations, shadow copies, and other policy-related functions.
- **Probe** is the RTT times from the health-checking subsystem in the namespace software. This subsystem sends periodic requests to every back-end share that is connected to an ARX volume.

**Guidelines: NFS RPC
Table**

NFS RPC - Each row of the NFS table shows the average RTTs for a particular NFS-RPC request. Each column shows the source of the RPC, as described above.

**Guidelines: NFS Error
Table**

Errors appear in a separate table under the NFS statistics. The table contains the following counters, with the same columns as the RPC table:

- **FormatError** is the number of malformed NFS packets received from the filer(s).
- **NetworkError** counts the send and receive failures.
- **ResourceError** is the number of times that the ARX software ran out of resources. Contact F5 Support if you see these errors.
- **RPCError** counts any errors from the RPC layer.
- **TimeoutError** is the number of timeouts waiting for an NFS response.

**Guidelines: CIFS SMB
Table**

CIFS SMB - Each row in the CIFS table shows the average RTTs for a given CIFS (SMB) request. The columns show the source of each SMB, as above.

Guidelines: CIFS Error Table

Errors appear in a similar table under the CIFS statistics, with the following fields:

- **FormatError** is the number of malformed SMB (CIFS) packets received from the filer(s).
- **NetworkError** counts the send and receive failures for SMB traffic.
- **ResourceError** shows the number of times that the ARX software had insufficient resources to complete the transaction. Contact F5 Support if you see these errors.
- **SignatureError** counts any SMB packets with missing or incorrect signatures. You can use the [cifs filer-signatures](#) command to change the SMB-signing policy for the current namespace.
- **SMBError** is the number of SMB packets that failed with errors that are not directly related to any of the above errors.
- **TimeoutError** is the number of timeouts waiting for an SMB response.

Guidelines: Clearing Statistics

You can use the [clear statistics filer](#) command to clear the statistics from all variations of `show statistics namespace`. If you use that command to clear the statistics from one share in a volume but not another, the volume-level statistics in this command are inconsistent; one share may have statistics for 2 months and the other share may have statistics for only 5 minutes. To confirm that the volume has consistent statistics, run this command on each of the volume's shares and verify that the **Reset...** field has the same date and time for each of them.

Sample

```
bstnA> show statistics namespace medarcv volume /rcrds response-detail
shows RTT statistics for the volume, "medarcv~/rcrds." See Figure 40.18 on page 40-63 for sample output.
```

show statistics namespace ... summary

Purpose Use the `show statistics namespace ... summary` command to show request counts, response counts, and average round-trip times (RTTs) between a namespace and its back-end-filer shares.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics namespace name [volume vol [share {shr | all}]] [summary]`

name (1-30 characters) identifies the namespace.

vol (optional; 1-1024 characters) specifies one volume in the namespace.

shr | **all** is a required choice if you use the optional **share** keyword:

shr (1-64 characters) specifies one share in the volume.

all shows all shares in the volume. This creates a separate table for each share; if you omit the **share all** option, the output contains a single table showing the sums of all shares.

summary (optional) shows request and response counts per ARX request type, and shows the average RTT for each request type. This also shows error counts.

Guidelines This command shows the request counts, response counts, and round-trip times (RTTs) from the chosen namespace, volume or share to its back-end filers. These are cross-referenced by request format and by the software component that made the request. To show the detailed request counts, you can use [show statistics namespace ... request-detail](#). To see the detailed RTTs for all of these requests, you can use [show statistics namespace ... response-detail](#). The output of all three commands includes the counts of various errors. To see the raw read/write statistics for the same namespace, volume, or share, you can use the [show statistics namespace ... fastpath](#) command. As with this command, you can see these statistics summarized for an entire namespace, focused on a single volume, or focused on one share.

Guidelines: Output The output shows the request counts, response counts, and round-trip times (RTTs) for specific NFS and/or CIFS requests. Each selected volume has a separate table of summary statistics with the following fields:

Namespace and

Volume identify the volume.

All shares in volume appears if you did not use the **share** keyword to specify a single share. This indicates that the statistics are at a volume level; they are the sum of the statistics for all of the volume's shares. If you select a particular share, the following fields appear instead:

- Share identifies the share, as it is named in the ARX configuration. The [show global-config namespace *name*](#) command shows the share names in the ARX configuration.

**Guidelines: Output
(Cont.)**

- Filer is the name of the external filer that hosts the share. Again, this is the name of the filer in the ARX configuration; you can use the [show external-filer *filer-name*](#) command to see the IP address and/or SPN for *filer-name*.
- NFS Export or
- CIFS Share is the name of the export or share at the filer. Both names appear if this is used as a multi-protocol share.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone [reloads](#) the chassis or uses [clear statistics filer](#) on the share.

The remainder of the output contains up to four tables: summaries for NFS RPCs, counts of NFS Errors, summaries for CIFS SMBs, and/or counts of CIFS Errors.

**Guidelines: NFS RPC
Table**

NFS RPC - Each row of the NFS table shows the summaries for a particular NFS-RPC request. This has the following columns:

- Req Count is the total number of requests from this namespace, including requests from the control plane, data plane, policy engine, and probe subsystem.
- Resp Count is the total number of responses from this namespace's filers. These counts should match the request counts.
- Avg RTT (uSec) is average round-trip time (RTT) for the request/response pairs.

**Guidelines: NFS Error
Table**

Errors appear in a separate table under the NFS statistics. The table contains the following counters:

- FormatError is the number of malformed NFS packets received from the filer(s).
- NetworkError counts the send and receive failures.
- ResourceError is the number of times that the ARX software ran out of resources. Contact F5 Support if you see these errors.
- RPCError counts any errors from the RPC layer.
- TimeoutError is the number of timeouts waiting for an NFS response.

**Guidelines: CIFS SMB
Table**

CIFS SMB - Each row in the CIFS table shows the summaries for a given CIFS (SMB) request. This has the same columns as the NFS RPC table.

Guidelines: CIFS Error Table

Errors appear in a similar table under the CIFS statistics, with the following fields:

- **FormatError** is the number of malformed SMB (CIFS) packets received from the filer(s).
- **NetworkError** counts the send and receive failures for SMB traffic.
- **ResourceError** shows the number of times that the ARX software had insufficient resources to complete the transaction. Contact F5 Support if you see these errors.
- **SignatureError** counts any SMB packets with missing or incorrect signatures. You can use the [cifs filer-signatures](#) command to change the SMB-signing policy for the current namespace.
- **SMBError** is the number of SMB packets that failed with errors that are not directly related to any of the above errors.
- **TimeoutError** is the number of timeouts waiting for an SMB response.

Guidelines: Clearing Statistics

You can use the [clear statistics filer](#) command to clear the statistics from all variations of `show statistics namespace`. If you use that command to clear the statistics from one share in a volume but not another, the volume-level statistics in this command are inconsistent; one share may have statistics for 2 months and the other share may have statistics for only 5 minutes. To confirm that the volume has consistent statistics, run this command on each of the volume's shares and verify that the **Reset...** field has the same date and time for each of them.

Sample

```
stoweA> show statistics namespace lodges summary
shows summary statistics for the namespace, "lodges." See Figure 40.19 for sample output.
```

strict-attribute-consistency

Purpose This command applies only to a share in a multi-protocol (NFS and CIFS) volume with one or more NFS-only directories. An *NFS-only* directory has a name that cannot be expressed in both NFS and CIFS, so its back-end filer has created a filer-generated name (*FGN*) for CIFS clients. The CIFS attributes for NFS-only directories are obscured because it is not possible to deterministically find the directory's CIFS-side FGN. Directory duplication, called *striping*, is required for many standard operations in a managed volume, including file migration ([place-rule](#), [auto-migrate](#), [balance](#)) and share removal ([remove-share migrate](#), [remove-share nomigrate](#)). The volume can never stripe an NFS-only directory if strict-attribute consistency is required. The `no strict-attribute-consistency` command allows striping of NFS-only directories; it permits the volume to ignore any CIFS attributes that it cannot find. The volume replaces any undiscovered CIFS attribute with a 0 (zero).

Use the affirmative form, `strict-attribute-consistency`, for multi-protocol volumes where NFS-only striping is not required.

Modes gbl-ns-vol-shr

Security Role(s) storage-engineer or crypto-officer

Syntax `no strict-attribute-consistency`
`strict-attribute-consistency`

Default(s) `strict-attribute-consistency`

Guidelines This command is not allowed in a CIFS-only or NFS-only namespace. Strict-attribute consistency, the default, is recommended for most situations. Use the `no` form of this command to permit migrations of one or more NFS-only directories.

◆ Important

If you migrate to a share with `no strict-attribute-consistency`, NFS-only directories lose CIFS attributes at the destination share.

You may want to re-enable `strict-attribute-consistency` on the share after completing a one-time migration (such as a [remove-share migrate](#)).

Guidelines (Cont.) The best practice in this case is to rename all NFS-only directories so that they are accessible to CIFS clients. If all directories are renamed, you can keep the `strict-attribute-consistency` setting for all shares in the volume and support all forms of migration and striping.

The following characters are supported for NFS directory names, but not for CIFS:

any control character, /, \, :, *, ?, >, <, ", or |

Any of these names result on an FGN at the back-end filer, which makes the directory "NFS-only."

Additionally, NFS supports case collisions and CIFS does not. A *case collision* is two files or directories whose names differ only in case: for example, "oneDir" and "ONEDIR."

Note that NFS clients can create NFS-only directories while the volume is in service. If `strict-attribute-consistency` is enabled, any such directory-creation (or rename) disables all striping for the directory. It also makes the directory and its contents inaccessible to CIFS clients, regardless of the `strict-attribute-consistency` setting.

To rename the directory, access it through one of the volume's `nfs` exports.

Samples

```
bstnA(gbl-ns-vol-shr[insur~/claims~precs])# no strict-attribute-consistency
```

allows the volume to drop any CIFS-directory attributes that it cannot find when it stripes NFS-only directories in the 'precs' share.

```
bstnA(gbl-ns-vol-shr[wwmed~/acct~bills])# strict-attribute-consistency
```

forces the volume to reconcile all CIFS attributes before striping any directory in the 'bills' share. NFS-only directories cannot be striped, but no CIFS attributes are ever discarded.

- [auto-migrate](#)
- [balance](#)
- [remove-share migrate](#)
- [remove-share nomigrate](#)

wait-for remove

Purpose Use the `wait-for remove` command to wait until a volume-removal or share-removal operation has completed.

Mode (any)

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `wait-for remove namespace vol-path [share] [timeout timeout]`

namespace (1-30 characters) is the name of the namespace.

vol-path (1-1024 characters) identifies the volume.

share (optional, 1-64 characters) is the share that is being removed.

timeout (optional, 1-2096) is the timeout value in seconds.

Default(s) *timeout* - none, wait indefinitely

Guidelines This command is useful in CLI scripts.

When removing a volume with `remove namespace ... volume`, or a share with `remove-share migrate` or `remove-share nomigrate`, you can use the `wait-for remove` command to wait for the operation to complete. This can be useful for CLI scripts, which you can copy onto the switch (with `copy ftp`, `copy scp`, `copy {nfs|cifs}`, or `copy tftp`), and `run`.

If you set a *timeout* and it expires before the volume or share is removed, the command exits with a warning. To interrupt the `wait-for remove` command, press `<Ctrl-C>`.

Samples `bstnA> wait-for remove ns21 /vol4`

waits indefinitely for the '/vol4' volume to be removed from the 'ns21' namespace. The CLI prompt does not return until the volume-removal operation is complete.

`bstnA> wait-for remove ns66 /vol31 rxbills timeout 60`

waits up to 60 seconds for the '/vol31~rxbills' share to be removed from the 'ns66' namespace.

Related Commands `remove namespace ... volume`
`remove-share migrate`
`remove-share nomigrate`

CIFS-Service Troubleshooting Tools

cifs promote-subshares

Purpose A managed volume duplicates all CIFS subshares between its back-end filers. That is, if a CIFS share exists below one of its back-end shares, that lower share (called a subshare) and its ACL is duplicated to all of its peer subshares in the managed volume. In former software releases, the managed volume used a special name for the replicated subshares, with the format “_acopia_subshare-name_id\$” (for example, “acopia_CELEBS_3\$”). You can use this command to promote all such subshare names to a native name, such as “CELEBS.” You can invoke this command on one share at a time.

Mode priv-exec

Security Role(s) storage-engineer or crypto-officer

Syntax `cifs promote-subshares namespace ns volume vol share shr [tentative]`

ns (1-30 characters) identifies the share’s namespace. Use the [show namespace](#) command for a list of all namespaces.

vol (optional, 1-1024 characters) identifies the managed volume with CIFS subshares. The [show global-config namespace *ns-name*](#) command lists all volumes (and other parameters) in a particular namespace.

shr (optional, 1-64 characters) is the share with ARX-generated subshares.

tentative (optional) creates a report showing all of the ARX-generated subshares at the back-end share, and showing the native share names that the managed volume would give to each subshare. You can use this option to confirm that the volume would rename the subshares as needed, then you can re-run the command without the option to actually perform the renames.

Default(s) None

Guidelines When you use the command without the **tentative** option, the CLI prompts for confirmation before it performs any subshare renames. Enter **yes** to proceed with the rename operations.

This command generates a report to show the results (or tentative results) of the operation. The report name has a prefix of “cifsPromoteSubshares” and a time stamp; the exact name of the report appears after you enter the command.

You can use the **tentative** option to generate the report, which reveals any subshares with names that were generated unnecessarily. (Some subshare names are generated to avoid a collision with another share name on the same back-end filer; you cannot use native names for those shares.) If you find any such subshare names, you can re-run the command without the **tentative** option to change them to their native names.

If the volume has no [modify](#) set, preventing it from changing any configuration on its back-end filers, this operation always runs as though the **tentative** flag is raised. The command generates a report but does not change any subshare names.

Use the [filer-subshares](#) command to enable subshare support in the managed volume.

Samples `bstnA# cifs promote-subshares namespace medarcv volume /rcrds share bulk tentative`

```
% INFO: Promote subshares operation completed. See report
'cifsPromoteSubshares_201009020052.rpt' for more detail.
```

runs a tentative command to promote all subshares in the “bulk” share. The report shown in the prompt lists all of that share’s subshares (if there are any) and the new names that the command would give them. A sample report, showing no subshares that require promotion, is in [Figure 41.1 on page 41-4](#).

Had the report shown any subshares that required promotion, you could promote them to native names by re-running the command without the `tentative` argument.

```
bstnA# cifs promote-subshares namespace ns4 volume /vol share shr3
```

```
This operation renames subshares on filer fs14[172.16.195.44]
corresponding to ARX-generated subshares under share
bulk in use by front-end passthrough exports for volume /vol.
Continue? [yes/no] yes
```

```
% INFO: Promote subshares operation completed. See report
'cifsPromoteSubshares_201003161659.rpt' for more detail.
```

promotes all subshares in the “shr3” share. The report lists all of that share’s subshares and their new names.

clear statistics cifs authentication

Purpose Use this command to clear the authentication statistics for a front-end CIFS service.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics cifs authentication {fqdn | all}`

fqdn (1-128 characters) is the fully-qualified domain name (for example, “myserver.organization.org”) for a CIFS service. Use [show cifs-service](#) to see a list of CIFS services.

all clears statistics for all CIFS services. The CLI requires confirmation before doing this.

Default(s) None

Guidelines The [show statistics cifs authentication](#) command shows counters and statistics for all CIFS authentications. Use this command to clear the traffic counters for one (or all) CIFS services.

If you clear **all** statistics with this command, the CLI prompts for confirmation; enter **yes** to proceed.

Sample `bstnA# clear statistics cifs authentication all`

Confirmation of this command causes CIFS authentication statistics to be cleared for all CIFS services.

Proceed [yes/no] **yes**

clears all CIFS-authentication statistics from the system.

Related Commands [show statistics cifs authentication](#)
[show cifs-service](#)

clear statistics cifs path-cache

Purpose	Each NSM processor keeps a cache of file and directory paths for CIFS managed volumes. The NSM processors learn these paths from the managed-volume software, then store them in their path cache. The system keeps running statistics on the usage of the path cache. This command clears the path-cache statistics for a CIFS-supporting namespace or volume.
Mode	priv-exec
Security Role(s)	network-technician, network-engineer, storage-engineer, or crypto-officer
Syntax	<p>clear statistics cifs path-cache namespace [volume [slot.processor]]</p> <p><i>namespace</i> (1-30 characters) is the name of a namespace. Use the show namespace command for a list of all namespaces.</p> <p><i>volume</i> (optional, 1-1024 characters) focuses on the path cache for a single volume. The show global-config namespace ns-name command lists all volumes (and other parameters) in a particular namespace. If you omit this, the statistics are cleared for all volumes in the <i>namespace</i>.</p> <p><i>slot.processor</i> (optional: for example, 1.4) focuses on a single NSM processor's cache. Each processor keeps an individual cache for each volume.</p>
Default(s)	None
Guidelines	<p>Use the cifs path-cache command to enable the CIFS path-cache for a volume. This command clears statistics only. It does not clear any path-cache entries.</p> <p>The show statistics cifs path-cache command shows counters and statistics for the path cache. Use this command to clear the counters for CIFS-supporting volumes. The CLI prompts for confirmation before clearing the statistics; enter yes to proceed.</p>
Samples	<pre>bstnA# clear statistics cifs path-cache insur /rcrds 3.3</pre> <p>Clear path-cache statistics? [yes/no] yes clears the path-cache statistics that processor 3.3 kept for the “insur~/rcrds” volume.</p> <pre>bstnA# clear statistics cifs path-cache medarcv</pre> <p>Clear path-cache statistics? [yes/no] yes clears all path-cache statistics on all volumes in the “medarcv” namespace. This clears the statistics at all NSM processors.</p>
Related Commands	<p>cifs path-cache</p> <p>show statistics cifs path-cache</p> <p>show cifs-service path-cache</p>

clear statistics cifs symlinks

Purpose CIFS clients can de reference NFS symbolic links (or symlinks) in a multi-protocol volume. Use this command to clear the statistics for these de referencing operations.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics cifs symlinks [volume-group id]`

volume-group id (optional) narrows the scope to a single volume group. A *volume group* is a failure domain for a group of volumes in the same namespace. If you omit this option, the command clears statistics from all volumes on the system.

Default(s) None

Guidelines The [show statistics cifs symlinks](#) command shows counters and statistics for all symlink de referencing operations. The statistics only include symlink operations on behalf of CIFS clients; NFS clients perform symlink de referencing at the client machine. Use this command to clear the symlink counters for one (or all) volume groups.

The CLI prompts for confirmation before clearing any statistics; enter **yes** to proceed.

Sample `bstnA# clear statistics cifs symlinks`

```
Clear statistics for CIFS symlink resolution for all Volume Groups?
```

```
Are you sure? [yes/no] yes
```

```
clears all CIFS-symlink statistics from the system.
```

Related Commands [show statistics cifs symlinks](#)

clear statistics cifs work-queues

Purpose CIFS volumes use internal *work queues* to process CIFS commands, CIFS authentication requests, and all the component tasks required to accomplish them. The volume software keeps statistics for the amount of processing time used by each work item in these queues. Use this command to clear those work-queue statistics.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics cifs work-queues volume-group vg-id`
`clear statistics cifs work-queues instance instance-id`

volume-group *vg-id* (optional, 1-255) chooses a volume group. A *volume group* is a failure domain for a group of volumes in the same namespace. You can use [show volume-group](#) for a list of all volume groups on the system, and to see which volumes are assigned to each volume group.

instance *instance-id* (optional) chooses a volume group by its namespace-instance ID. Instance IDs often appear in syslog messages, which you can view with [show logs syslog](#). You can also see instance IDs with [show namespace all](#), which shows full details on all namespaces in the system.

Default(s) None

Guidelines The [show statistics cifs work-queues](#) command shows counters and statistics for all CIFS work queues. These statistics include time required to process each work item, number of work items completed and discarded from each queue, average processing time for each CIFS operation, and average round-trip times between the volume(s) and their back-end CIFS servers. The back-end-server statistics can only be cleared by the [clear statistics filer](#) command; this command clears all the remaining statistics.

The CLI prompts for confirmation before clearing any statistics; enter **yes** to proceed.

Sample `bstnA# clear statistics cifs work-queues volume-group 2`
 Statistics for filer shares are not cleared by this command.
 It may take up to 30 seconds after the command for other statistics to be cleared.

```
Clear CIFS work-queue statistics? [yes/no] yes
clears all CIFS-work-queue statistics for volume group 2.
```

Related Commands [show statistics cifs work-queues](#)
[clear statistics filer](#)

clear statistics domain-controller

Purpose The ARX keeps statistics for its NTLM/NTLMv2 authentications against each of its domain controllers (DCs). Use this command to clear the statistics for a particular DC, or for all DCs at once.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics domain-controller {ip-address | all}`

ip-address (for example, 1.2.3.4) identifies the DC for which you want to clear statistics. The [show active-directory](#) command shows all DCs that are known to the ARX.

all clears NTLM statistics for all DCs.

Default(s) None

Guidelines The [show statistics domain-controller](#) command shows counters and statistics for NTLM and NTLMv2 authentications from all CIFS front-end services with constrained delegation. Use this command to clear the NTLM counters against a particular DC.

The CLI prompts for confirmation before clearing any statistics; enter **yes** to proceed.

Sample

```
bstnA# clear statistics domain-controller 192.168.25.102
Clear domain-controller statistics? [yes/no] yes
```

clears all NTLM/NTLMv2 statistics for the DC at 192.168.25.102.

Related Commands [show statistics domain-controller](#)
[show active-directory](#)

clear statistics domain-controller load-balancing

Purpose The ARX balances its Kerberos requests between multiple domain controllers (DCs) in the same Windows Domain, and keeps count of the number of requests to each DC. The ARX keeps these counters until the next reboot. Use this command to clear the counters immediately.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer, or crypto-officer

Syntax `clear statistics domain-controller load-balancing`

Default(s) None

Guidelines The [show statistics domain-controller load-balancing](#) command shows counters for all Kerberos requests to all DCs. Use this command to clear those counters. The CLI prompts for confirmation before clearing any statistics; enter **yes** to proceed.

Sample
bstnA# `clear statistics domain-controller load-balancing`
Clear load-balancing statistics? [yes/no] **yes**

clears all Kerberos-request counters for all DCs.

Related Commands [show statistics domain-controller load-balancing](#)
[show active-directory](#)

clear subshare-cache

Purpose A managed volume that supports [filer-subshares](#) keeps all of its subshare information in cache memory. This decreases the number of RPC calls between the ARX and its back-end filers during `sync subshare` operations. On the advice of F5 personnel, you can use this command to clear this cache.

Mode `priv-exec`

Security Role(s) `storage-engineer` or `crypto-officer`

Syntax `clear subshare-cache [ext-filer-name]`

ext-filer-name (optional, 1-64 characters) identifies an external filer with outdated subshare information. This is the name of the filer in the ARX configuration. For a list of configured external filers, use [show external-filer](#).

Default(s) `None`

Guidelines Use the [filer-subshares](#) command to enable filer subshares for a volume. Then use [export \(gbl-cifs\) ... filer-subshare](#) to export a single subshare, or [sync subshares from-namespace](#) to export all of the subshares from the back-end filers.

A *filer subshare* is any CIFS share that is inside an imported CIFS share. A client who connects to a front-end subshare, if the subshares are configured as described above, is passed through the managed volume directly to a corresponding subshare on a back-end filer. The filer can then enforce its subshare ACL, as opposed to the top-level ACL of the imported share. Each front-end subshare (visible to your CIFS clients) maps to one or more back-end subshares. The state of each filer share and share ACL resides in a memory cache; you can use [show subshare-cache](#) to see the contents of the cache.

The [sync subshares from-namespace](#) and [sync subshares from-service](#) commands clear this cache automatically before they begin, but only for the filers affected by the command. You can use this command to clear the entire cache, or the cache for one filer where you are sure that subshare information has changed. This slows the performance of future `sync subshare` commands, but ensures that the cache is updated with the latest subshare information on the back-end filer(s).

Sample `bstnA# clear subshare-cache fs2`
clears the subshare-cache for the external filer named "fs2."

Related Commands [filer-subshares](#)
[sync subshares from-namespace](#)
[sync subshares from-service](#)
[show subshare-cache](#)

close cifs file

Purpose You can use the `close cifs file` command to close a file that is being held open by a CIFS client.

Modes `priv-exec`

Security Role(s) `network-technician`, `network-engineer`, `storage-engineer`, or `crypto-officer`

Syntax `close cifs file fqdn slot.processor fid file-id`

fqdn (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, “www.organization.org”). This identifies the host for the open file.

slot.processor (for example, 2.4) is the NSM slot and processor that is hosting the CIFS session, from the output of [show cifs-service open-files](#).

file-id (0-65535) identifies the file to close. You can also find this in the output of [show cifs-service open-files](#).

Default(s) `None`

Guidelines Some Windows applications open a file, read it, immediately close it, and then present its contents to the user as though the file was still open. Notepad and WordPad are two commonly-used applications that use this practice. These applications do not actually hold the files open, so other clients can still access the file for writing. Other applications, such as Microsoft Word, hold the file open until the user closes it through the application interface. This prevents access from any competing applications or clients. This command closes any such file from the CLI.

Use [show cifs-service open-files](#) to see all files that are currently held open by CIFS clients. This is the same “open files” listing seen through MMC.

Use [show cifs-service user-sessions](#) to find clients with open CIFS sessions. You can also use [drop cifs-service user-session](#) to disconnect a client session.

An authorized Windows client can perform this operation from an MMC interface (or a similar Windows-management client), assuming the CIFS service has [browsing](#) enabled and the client belongs to a properly-enabled [windows-mgmt-auth](#) group.

Sample `bstnA# close cifs file ac1.medarch.org 2.6 fid 1241`
`slot:2.6 CIFS open file with FID:1241 closed.`
closes an open CIFS file that is hosted by processor 2.6, through a CIFS service at “ac1.medarch.org.”

Related Commands [cifs](#)
[show cifs-service open-files](#)
[show cifs-service user-sessions](#)
[browsing](#)
[windows-mgmt-auth](#)

drop cifs-service user-session

Purpose	Use the <code>drop cifs-service user-session</code> command to drop a client connection to a CIFS service.
Modes	<code>priv-exec</code>
Security Role(s)	<code>network-technician</code> , <code>network-engineer</code> , <code>storage-engineer</code> , or <code>crypto-officer</code>
Syntax	<code>drop cifs-service user-session fqdn slot.processor ipaddress client-ip</code> <i>fqdn</i> (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, “www.organization.org”). This identifies the host for the session. <i>slot.processor</i> (for example, 1.4) is the NSM slot and processor that is hosting the session, from the output of show cifs-service user-sessions . <i>client-ip</i> (an IP address in <i>a.b.c.d</i> format) identifies the client to drop.
Default(s)	None
Guidelines	This is useful for malfunctioning CIFS clients that fail to tear down their connections, or for testing. Use show cifs-service user-sessions to find clients with open CIFS sessions. You can also use show cifs-service open-files to see all files that are currently open through CIFS (and holding an exclusive-write lock). An authorized Windows client can perform this operation from an MMC (or similar) interface, assuming the CIFS service has browsing enabled and the client belongs to a properly-enabled windows-mgmt-auth group.
Sample	<pre>bstnA# drop cifs-service user-session ac1.medarch.org 2.5 ipaddress 172.16.100.214</pre> <p>disconnects a CIFS client at 172.16.100.214.</p>
Related Commands	cifs show cifs-service user-sessions show cifs-service open-files browsing windows-mgmt-auth

show cifs-service client-activity

Purpose Use the `show cifs-service client-activity` command to show details about one client's connection to a CIFS service.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show cifs-service client-activity fqdn ip-address [connection-id [open-files | pending-transactions]]`

fqdn (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, "www.organization.org").

ip-address is the IP address of a single client.

connection-id (optional) identifies a single client connection. You can get this ID from the summary output, then rerun the command with the ID to show details about the client connection.

open-files (optional, if you chose a *connection-id*) shows only the Open Files table for the given client connection.

pending-transactions (optional, if you chose a *connection-id*) shows only the pending transactions for the given client connection, if any.

Guidelines: Summary Output

The simplest syntax outputs the following fields, table, and summary:

Client IP Address is the IP address of the client, specified on the command line.

SlotProc is the NSM processor that is hosting the CIFS session, in *slot.processor* format.

Then a table shows all of the connections from the above filter. Each connection appears on two rows. These rows contain the following fields:

- **Conn** is an integer ID to identify the front-end CIFS connection. You can rerun this command with this specific ID to see details about the connection, such as the specific files that the client is holding open.
- **Port** is the port on the NSM to which the client is connected.
- **Age** is the number of seconds that the client connection has been up.
- **Sessions** is the number of sessions from the client to the CIFS service (at the specified NSM processor).
- **Tree Cons** is the number of different front-end shares to which client is connected. These may be different volumes in the same namespace and/or different share names for the same front-end share (see [export \(gbl-cifs\)](#)).
- **Open Files** is the number of files open in this client session. Details on the open files appear in a table below.
- **Username** appears on its own line. This is the name provided by the CIFS client.

Total number of connections is the sum of the above client connections.

Guidelines: Detailed Output for One Client Connection

If you specify a *connection-id* in the command, the output also includes two tables. You can use the **open-files** or **pending-transactions** keyword to include only one of these two tables.

**Guidelines: Open
Files Table**

The Open Files table contains three rows per open file. The top row shows various ID's used for the client's front-end and back-end connections:

FE Conn identifies the front-end connection to the client. This is the *connection-id* entered in the command.

BE Conn identifies the back-end connection to a file server.

FE UID is the client's User ID. The CIFS service provides the UID to the client after a successful authentication. This is only valid for the duration of the CIFS-client session.

BE UID is the User ID used for the back-end connection. The CIFS service provides the UID to the client after a successful authentication to the back-end server. This is only valid for the duration of the CIFS session.

FE TID is the client's Tree-connection ID. This identifies the client's CIFS connection to a particular resource, such as a directory tree offered by the front-end service. The TID changes for each CIFS session (whenever the connection is broken and re-established).

BE TID is the Tree-connection ID for the back-end connection.

FE FID is the front-end File ID for this file. This changes with each CIFS-client session.

BE FID is the back-end File ID for this file.

In cases where the back-end connection is to an internal process instead of a filer, the BE IDs are 0 (zero).

The second row is the FE Path to the open file. This is the virtual path, as seen by the front-end client.

The final row is the BE Path to the open file. This is the physical path on the back-end server.

Guidelines: Pending Transactions Table

Some CIFS transactions may wait in a queue before they get a response, such as messages from the NSM processes to back-end filers or to ACM processes. These are called *pending transactions*. This table lists all pending transactions, two rows per transaction. The top row shows CIFS IDs from the front-end (FE) perspective, along with the state of the associated back-end transaction:

FE Conn is the client ID from the front-end CIFS service. The service assigns this to the client when it establishes a TCP connection. The CIFS service uses this internally to identify the client session.

FE UID is the client's User ID. The CIFS service provides the UID to the client after a successful authentication. As above, this only valid for the duration of the CIFS session.

FE MID is the Multiplex ID. The client software sets this. Whenever the client has its own pending transaction (waiting for response from the ARX's CIFS service), it can send a packet with a new MID to differentiate the new transaction.

FE PID is the process ID, provided by the client.

FE TID is the client's Tree-connection ID. This identifies the client's CIFS connection to a particular resource, such as a directory tree offered by the front-end service. The TID changes for each CIFS session (whenever the connection is broken and re-established).

FE FID is the File ID for this file. This also changes with each CIFS session.

State explains the current state of the transaction. This is the state of the CIFS connection between the NSM process and the remote process; unlike the preceding fields on the top row, this concerns the back-end (BE) CIFS session.

The remote process is either a filer (referenced as the "backend" or the "filer" in the state text) or a namespace process (called "dnas" in the state text).

The bottom row shows the same IDs for the back-end (BE) CIFS session with either a back-end filer or a namespace process on the ACM. If the latter, there is no authentication, tree connection, or file involved, so the UID, TID, and FID are all 0 (zero). The final field, **Command**, is the CIFS command that is pending.

Guidelines: Table Summaries

Total Open Files and

Total Pending Transactions appear beneath the above tables.

Guidelines: Manipulating the Client Session

Use the [show cifs-service user-sessions](#) command for a list of all client connections to a CIFS service. You can use [drop cifs-service user-session](#) to disconnect a client session. An authorized Windows client can show and drop CIFS sessions from a Windows-management interface like MMC, assuming the CIFS service has [browsing](#) enabled and the client belongs to a properly-enabled [windows-mgmt-auth](#) group.

For statistics on CIFS authentication, use [show statistics cifs authentication](#).

Samples

```
bstnA> show cifs-service client-activity ac1.medarch.org 172.16.100.20
lists all client sessions with the "ac1.medarch.org" CIFS service. See Figure 41.2 for sample output.
```

```
bstnA> show cifs-service client-activity ac1.medarch.org 172.16.100.20
24
```

lists one client session with the "ac1.medarch.org" CIFS service. This uses the client-connection ID from the previous output, 24. See [Figure 41.3 on page 41-18](#) for sample output.

FID - File Identifier

show cifs-service exports

Purpose Use the `show cifs-service exports` command to list CIFS exports and their client-connection statistics.

Mode (any)

Security Role(s) `crypto-officer, storage-engineer, network-engineer, network-technician, or operator`

Syntax `show cifs-service exports {fqdn [slot.processor] | all}`

fqdn (1-128 characters) specifies a particular CIFS service (for example, “www.company.com”).

slot.processor (optional: for example, 2.3) focuses on the connections to a particular NSM processor.

all shows the connections statistics for all CIFS services.

Guidelines The output is a table of CIFS shares that are exported by each NSM processor. Each row in the table describes a single export:

Proc is the NSM that is exporting the share. Use [show processors](#) for a full list of all processors on the ARX.

Export is the name of the CIFS share as seen by clients. This is created as part of the [export \(gbl-cifs\)](#) command.

Namespace identifies the [namespace](#) behind this CIFS share. This is also chosen with the [export \(gbl-cifs\)](#) command.

Virtual Path is the path to the CIFS share from the root of the volume. Again, this is from the perspective of the front-end client, and it is established by the [export \(gbl-cifs\)](#) command.

Tree Connects is the heading for a series of connection statistics:

Curr is the number of CIFS clients currently connected to the share and processor.

Peak is the highest number of simultaneous connections.

Total is the sum of all CIFS connections to the share.

To see the client sessions that are connected to the CIFS service, use [show cifs-service user-sessions](#). To disconnect a client session, use [drop cifs-service user-session](#). The [show cifs-service open-files](#) command shows all files that are currently open through CIFS (with an exclusive-write lock). A share farm cannot [auto-migrate](#) a file in this state; use [close cifs file](#) to close one from the CLI.

Samples `bstnA> show cifs-service exports all`
lists all exports from all CIFS services. See [Figure 41.4 on page 41-21](#) for sample output.

`bstnA> show cifs-service exports ac1.medarch.org 2.8`
lists all exports from a particular CIFS service and NSM processor. See [Figure 41.5 on page 41-22](#) for sample output.

show cifs-service kerberos-tickets

Purpose If a CIFS service authenticates its clients with Kerberos, it caches all of the *tickets* granted to its clients. The tickets have expiration times, and are cached by the CIFS service until they expire. Use the `show cifs-service kerberos-tickets` command to list the Kerberos tickets in the cache.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show cifs-service kerberos-tickets {fqdn | all} [user username]`

fqdn | **all** is a required choice:

fqdn (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, “www.organization.org”).

all shows the tickets granted by all CIFS-services.

username (optional: 1-128 characters) is used in a case-blind search: this shows all principals whose names start with this string. For example, “myuser” matches “myuser”, “MYUSER@myco.com,” and “myusername@myorg.org.”

Guidelines This command shows the Kerberos tickets granted by CIFS services. Kerberos authentication must be enabled for the service to grant any such tickets: use [cifs authentication kerberos](#) (in gbl-ns mode) to enable Kerberos for a namespace, and [domain-join](#) to join the CIFS service to a Windows domain so that Kerberos works. The output has a separate table of principals (clients) and their tickets for each CIFS service. It contains the following fields:

Service identifies the CIFS service by name. This is the FQDN of the CIFS service’s global server, used in the [cifs](#) command.

Principal is name of the client who requested the ticket(s).

Start Time(UTC) is the date and time when the CIFS service granted the ticket. As noted, this is not in local time.

Expiry Time(UTC) is the date and time when the ticket is due to expire next. As above, this is not in local time.

Service Principal is name of the server or Ticket-Granting Ticket that granted this ticket to the principal.

Renew Till only appears for renewable Ticket-Granting Tickets.

Total number of principals displayed,

Total number of ticket-granting-tickets ..., and

Total number of service tickets ... appear at the end of each CIFS-service section.

An SNMP trap appears if the ticket cache begins to fill up. Use [snmp-server traps](#) and [snmp-server trusthost](#) to set up SNMP traps, and/or use [email-event](#) to deliver the traps via E-mail. The [show health](#) output also shows this condition if it arises.

To see the client sessions that are connected to the CIFS service, use [show cifs-service user-sessions](#). Use the [show statistics cifs authentication](#) command for statistics on all CIFS-service authentications: Kerberos, NTLMv2, and NTLM.

Sample `bstnA> show cifs-service kerberos-tickets all`
lists all Kerberos tickets granted by all CIFS services. See [Figure 41.6 on page 41-24](#) for sample output.

show cifs-service open-files

Purpose Use the `show cifs-service open-files` command to list the files that CIFS clients are holding open.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show cifs-service open-files {fqdn [slot.processor] | all}`

fqdn (1-128 characters) is the fully-qualified domain name for one global server (for example, “www.organization.org”).

slot.processor (optional: for example, 1.3) focuses on the open files served by one NSM slot and processor.

all shows the open files for all CIFS-service offerings.

Guidelines This command shows all of the open files in a CIFS front-end service. Each open file is described with three rows of information.

The first row shows the file view that the clients see:

Proc is the NSM processor that is serving the file, in *slot.processor* format.

User IP is the IP address of the client that has the file open.

Mode shows the read/write mode used to open the file. This is either “Read+Write” or “Read.”

FID is the CIFS file ID for the file, as seen by the client application. Each NSM processor assigns its own set of file IDs, so the same file ID may be reused by multiple processors.

Virtual IP is the IP address that the client is using to access the file. This is established by the [virtual server](#) command.

Virtual Share is the name of the CIFS share from the client perspective. This is established by the [export \(gbl-cifs\)](#) command, or by a Windows-management application like MMC (if [browsing](#) is enabled for the CIFS service).

The second row contains more information, including the number of locks on the file and the back-end filer view:

User Name identifies the client with a username and domain name.

Locks is the number of *range locks* held by the client, if any. These are locks for ranges of bytes in the file.

Filer IP is the IP address of the back-end filer that hosts the open file.

Filer Share is the share name at the back-end filer.

Guidelines (Cont.) The Namespace row indicates the ARX namespace where the file resides.

The final two rows identify the open file:

Virtual Path is the pathname of the open file from the root of the ARX volume.

Path on Filer is the pathname of the open file from the root of the Filer Share shown above.

To close an open CIFS file, use [close cifs file](#). To see the client sessions that are connected to the CIFS service, use [show cifs-service user-sessions](#). An authorized Windows client can perform all of these operations from an MMC (or similar) interface, assuming the CIFS service has [browsing](#) enabled and the client belongs to a properly-enabled [windows-mgmt-auth](#) group.

Samples bstnA> `show cifs-service open-files ac1.medarch.org`
lists all open files in the “ac1.medarch.org” service. See [Figure 41.7](#).

bstnA> `show cifs-service open-files ac1.medarch.org 2.9`
focuses on files served by a particular processor, 2.9. See [Figure 41.8 on page 41-29](#).

Related Commands [cifs](#)

show cifs-service path-cache

Purpose Each NSM processor can keep a cache of file paths in memory. Whenever a CIFS client requests a file or directory path, the NSM processor queries namespace software (on the ACM) for the virtual path and records the answer in its cache. The next request for the same path goes to the cache instead of the namespace software. This decreases the number of repetitive path queries to namespace software, thereby increasing performance. Use the `show cifs-service path-cache` command to show all file/directory paths currently in the path cache.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show cifs-service path-cache namespace [volume [slot.processor]] [detailed]`

namespace (1-30 characters) is the name of a namespace. Use the [show namespace](#) command for a list of all namespaces.

volume (optional, 1-1024 characters) focuses on the path cache for a single volume. The [show global-config namespace ns-name](#) command lists all volumes (and other parameters) in a particular namespace.

slot.processor (optional: for example, 2.2) focuses on a single NSM processor's cache.

detailed (optional) shows the additional front-end export, “/acopia#,” if it is exported by this CIFS service. This export is automatically generated by a CIFS service with [browsing](#) enabled.

Guidelines Use the [cifs path-cache](#) command to enable the CIFS path cache for a volume.

At the top of the output is one line per selected volume, indicating whether or not the volume has CIFS path caching enabled. Below these lines is a table with all of the currently-cached file paths. Each file (or directory) path is described with three rows of information.

The first row shows the volume and share (and, possibly subshare) with the virtual path, and the NSM processor that has the path in its cache:

Volume is the name of the volume with this file path.

ShareName is the name of the share as it appears in the volume configuration. (The name of the filer share appears in the next row.)

SubShareName, if applicable, is the name of the subshare where this path resides. A subshare is any share under the imported share; see the documentation for the [filer-subshares](#) command.

slot.proc is the NSM processor that is serving the file, in *slot.processor* format.

Guidelines (Cont.) The second row contains more information:

`\\Filer\ShareName` identifies the back-end share for the cached path. The external-filer name is the one configured on the ARX; use `show external-filer` for a full list of all configured filers. The share name is the one configured on the filer itself.

`Age` is the age of the cache entry in seconds. After 120 seconds of non-use, the entry is invalidated; the next search for the path causes a new namespace query. This aging process keeps the cache from occupying excessive memory.

`State` is the current state of this cache entry. This can be “up” (the path is valid), “init,” “pending” (the NSM processor is waiting for a response from the namespace software), “down” (the path information is known to be stale), “none,” or “unknown.”

The final row identifies the virtual path:

`Path` shows the path from the client perspective. This always starts from the root of the volume.

Use the `show statistics cifs path-cache` command to show the total path-cache usage since the last ARX reboot.

Samples `bstnA> show cifs-service path-cache medarcv`
lists all cached paths for the “medarcv” namespace. See [Figure 41.9 on page 41-32](#).

`bstnA> show cifs-service path-cache insur /claims`
shows the path cache for a specific volume, “insur~/claims.” See [Figure 41.10 on page 41-33](#).

show cifs-service transactions

Purpose Use the `show cifs-service transactions` command to list the active CIFS transactions from a particular client-IP address.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show cifs-service transactions ip-addr`

ip-addr (optional) is the source-IP address of a client machine.

Guidelines This command shows the current CIFS transactions between a client station and the ARX.

CIFS Transactions for the client: is the IP address of the client, entered in the command.

– via Processor shows the NSM processor that is hosting the CIFS session, in *slot.processor* format.

Src Port is the transport protocol (TCP or UDP) and port of the client, in *transport/port* format.

RPC is the name of the Remote Procedure Call invoked by the client transaction.

Status describes the current state of the transaction:

- Fwd Filer means that the NSM is forwarding the client connection to a back-end filer.
- Fwd Volume Group Proc indicates that the NSM is forwarding the client connection to managed-volume software on the control plane.
- Fwd Fastpath Proc means that the namespace software is forwarding the client application back to an NSM processor (the fastpath).

To see the client sessions that are connected to a particular CIFS service, use [show cifs-service user-sessions](#). Use [show cifs-service open-files](#) to see all files that are currently open through CIFS.

Sample `bstnA> show cifs-service transactions 172.16.100.20`
shows all currently-active transactions between the PC at 172.16.100.20 and any CIFS services on the switch. See [Figure 41.11](#) for sample output.

Related Commands [cifs](#)
[show cifs-service user-sessions](#)

CIFS Transactions for the client: 172.16.100.20 via Processor 2.7
```

Src Port	RPC	Status

TCP/61275	trans2	Unknown
TCP/61275	ntcreate	Unknown

show cifs-service user-sessions

Purpose Use the `show cifs-service user-sessions` command to list the client connections to a CIFS service.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax

```
show cifs-service user-sessions all [summary]
show cifs-service user-sessions all [namespace ns [volume vol]]
show cifs-service user-sessions fqdn [slot.processor]
show cifs-service user-sessions fqdn [namespace ns [volume vol]]
```

all shows all client sessions with all CIFS services.

summary (optional) shows client-authentication counters for all CIFS services.

namespace (1-30 characters) focuses on client sessions with one of the service's namespaces. Use the [show namespace](#) command for a list of all namespaces.

volume (optional, 1-1024 characters) focuses on the client sessions with a single volume. The [show global-config namespace ns-name](#) command lists all volumes (and other parameters) in a particular namespace.

fqdn (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, "www.organization.org"). This option focuses on the client connections to a single CIFS service.

slot.processor (optional: 2.1-12 on ARX-4000; 1.2-5 on ARX-2000; 1.2 on ARX-500 or ARX-VE) focuses on the sessions with one NSM slot and processor.

Guidelines For each selected [cifs](#) service, this command shows a table of current client sessions. The table contains one client session per row.

Proc is the NSM processor that is hosting the CIFS session, in *slot.processor* format.

IP Address is the source IP of the client.

Username shows the Windows credentials used by the client.

Auth is the authentication protocol used for the client connection. This is "Kerberos," "NTLMv2," "NTLM," or "Anon." The "Anon" means anonymous access; clients can log into the CIFS service (below) anonymously, but then have extremely limited access to the service's storage and other resources. Anonymous access to the IPC\$ share is only supported if the CIFS service is backed by a namespace with [cifs anonymous-access](#).

Sign shows whether or not the client connection is using SMB signing, a CIFS security feature. You can use the [signatures](#) command to determine (or change) SMB-signing support at the CIFS service.

Age is the time that the client connection has been up.

Guidelines (Cont.) Total number of users displayed appears at the bottom of the output.

To disconnect a CIFS client, use the [drop cifs-service user-session](#) command. Use [show cifs-service open-files](#) to see the open files in the service, or [close cifs file](#) to close one from the command line.

Guidelines: Summary Output The **all summary** options show counters for each type of client authentication. Each CIFS service appears in a row with the following counters:

Kerberos shows the number of Kerberos authentications to the service.

NTLMv2 and

NTLM are the number of clients that authentication with NTLMv2 or NTLM.

Anon shows the number anonymous accesses to this service. Clients can log into the CIFS service anonymously, but then have extremely limited access to the service's storage and other resources. Anonymous access to the IPC\$ share is only supported if the CIFS service is backed by a namespace with [cifs anonymous-access](#).

Samples `bstnA> show cifs-service user-sessions all`
lists all client sessions with all CIFS services on the switch. See [Figure 41.12](#) for sample output.

`bstnA> show cifs-service user-sessions all summary`
shows authentication counters for all CIFS services. See [Figure 41.13 on page 41-37](#) for sample output.

`bstnA> show cifs-service user-sessions ac1.medarch.org`
lists all client sessions with the CIFS service at "ac1.medarch.org." See [Figure 41.14 on page 41-37](#) for sample output.

`bstnA> show cifs-service user-sessions ac1.medarch.org namespace medarcv volume /rcrds`
lists all client sessions with a particular volume behind the CIFS service at "ac1.medarch.org." See [Figure 41.15 on page 41-38](#) for sample output.

`bstnA> show cifs-service user-sessions ac1.medarch.org 2.7`
narrows the list of client sessions to those that are hosted by a single processor, 2.7. For sample output, see [Figure 41.16 on page 41-38](#).

show fastpath cifs-signatures

Purpose Use the `show fastpath cifs-signatures` command to show counters and statistics for SMB signing. *SMB signing* is a CIFS security feature for client/server communication, where all packets contain a digital signature that the sender creates and the receiver verifies. This command shows counters for various SMB-signing activities, both on the client side and the filer side.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show fastpath cifs-signatures [slot.processor]`

slot.processor (optional: for example, 1.3) focuses on the signing statistics for one NSM slot and processor. If you omit this, the output contains statistics from all network processors.

Guidelines The default output shows the SMB-signing counters for all network processors. Each processor's counters appear in a separate table, with one row per counter. Each row shows the counter for the client side of the ARX and the filer side.

Outbound Unsigned SMBs is the number of unsigned CIFS packets sent from the ARX. The first number is the number of unsigned packets sent to clients, and the second is the number of unsigned packets sent to back-end filers.

Outbound Signed SMBs is the number of signed CIFS packets sent from the ARX to its clients, followed by the number of signed packets sent to back-end filers.

Inbound Unsigned SMBs counts the unsigned CIFS packets received by the ARX from clients and filers, respectively.

Inbound Verified SMBs is the number of signed CIFS packets received and verified by the ARX.

Inbound SMB Verify Errors counts all inbound CIFS packets that were rejected because their SMB signatures failed verification.

You can use the [cifs filer-signatures](#) command to enable, require, or disable SMB signing between a namespace and its back-end filers. The [signatures](#) command enables, requires, or disables SMB signing between a CIFS service and its clients.

Samples `bstnA(cfg)# show fastpath cifs-signatures`
shows the SMB-signing counters for all network processors. See [Figure 41.17 on page 41-40](#) for sample output.

`bstnA(cfg)# show fastpath cifs-signatures 2.8`
focuses on the SMB-signing counters for a particular network processor. See [Figure 41.18 on page 41-42](#) for sample output.

show statistics cifs authentication

Purpose Use the `show statistics cifs authentication` command to show counters and statistics for CIFS-authentication.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics cifs authentication {fqdn | all} [verbose]`

fqdn | **all** is a required choice:

fqdn (1-128 characters) is the fully-qualified domain name for one CIFS service (for example, “www.mystate.gov”).

all shows all authentication statistics from all CIFS-services.

verbose (optional) adds an additional table to the output. The table shows details for all CIFS-authentication failures.

Guidelines The default output shows the CIFS-service FQDN, its Windows Domain, and two tables.

Guidelines: Client Authentication Table Client Authentication, the first table, shows Kerberos, NTLMv2, and NTLM counters for front-end CIFS clients. These count the authentications between clients and the CIFS service.

The NTLM and NTLMv2 counts include Netlogon authentications and authentications through a separately-installed Secure Agent. A CIFS service that uses constrained delegation uses Netlogon, but a CIFS service that use unconstrained delegation uses the Secure Agent. You choose between constrained and unconstrained delegation when you run `domain-join` for the service.

Client authentication success and

Client authentication failure count the number of successful and failed authentication attempts for NTLM, NTLMv2, and Kerberos.

Principals in same realm is a Kerberos-only counter. This is the number of principals (users and hosts) who were in the same Kerberos realm (Windows domain) as the CIFS service. The CIFS-service realm/domain is established in the global-server configuration: use `show global server fqdn` to see it and `windows-domain (gbl-gs)` change it.

Principals in trusted realm is another Kerberos-only counter. These are the number of principals in a trusted realm. Trust relationships in realms are established by the local Active-Directory forest, which you configure on the ARX with `active-directory-forest` and its sub commands. Use `show active-directory` to show the Active-Directory forest on this ARX.

Principals in realm unknown counts the Kerberos-using principals who were outside any realm (domain) in the Active-Directory forest. This may indicate one or more realms/domains are missing from the ARX’s Active-Directory-forest configuration.

Guidelines (Cont.)

Errors contacting Secure Agent are NTLM and/or NTLMv2 errors for a CIFS service that uses unconstrained delegation or is not joined to its domain (see the [domain-join](#) command). These may indicate a connection problem with the Secure Agent's DC host. Use [show ntlm-auth-server](#) to show the host(s) for the Secure Agent, and use [show exports host dc-ip-address connectivity](#) to check connectivity to the DC.

SMB signing incompatibility counts the number of times that a client and the CIFS service could not successfully negotiate SMB signing. In this case, one end of the connection requires SMB signing and the other end of the connection refuses it. You can use the [signatures](#) command to set the SMB signing policy for the CIFS service.

Guidelines: Filer Authentication Table

Filer Authentication shows statistics for back-end Windows authentication. These count the authentications between the CIFS service and the back-end CIFS servers. Some of these statistics have different meanings depending on the delegation setting for the CIFS service; when the service joins its Windows domain (see [domain-join](#)), it is set for either constrained delegation or unconstrained delegation. Constrained delegation is more secure, and therefore recommended.

Control plane authentication success and

Control plane authentication failure count all authentication attempts that originate from the control plane. The control plane is where volumes, global-servers, and the policy engine run. These count the client requests that require processing at the control plane.

Fast path authentication success and

Fast path authentication failure are the authentications that do not require processing at the control plane; they are processed at the NSM only.

Cross-Realm TGTs granted applies only to Kerberos.

- For a CIFS service that uses constrained delegation, the CIFS service follows the Kerberos S4U protocol and obtains service tickets on behalf of its clients. This counts the number of cross-realm service tickets that the service obtained.
- For unconstrained delegation, the CIFS client presents a Ticket-Granting Ticket (TGT) to the CIFS service, which then uses that TGT to get a Service Ticket for a back-end filer. This counts the number of cross-realm TGTs that the DCs granted.

Cross-Realm TGTs denied are also Kerberos-only statistics, with different meanings for CIFS services with constrained or unconstrained delegation:

- For constrained delegation, this is the number of S4U service tickets that have been denied, where the client was in a different realm (or domain) from the CIFS service. A constrained CIFS service uses the Kerberos Service-for-User (S4U) protocol extension, where the CIFS service gets service tickets to its back-end filers on behalf of each of its Kerberos clients. If these tickets are denied, verify that the CIFS service still has an account configuration at a local DC, and that the account's password key has not expired. If the password key has expired, you must use [domain-join](#) to rejoin the CIFS service to its domain.
- For unconstrained delegation, the CIFS client presents a TGT to the CIFS service, which then uses that TGT to get a Service Ticket for a back-end filer. This counts the number of cross-realm TGTs that the DCs denied.

Guidelines: Filer Authentication Table (Cont.)

Cross-Forest TGTs granted, and

Cross-Forest TGTs denied are also Kerberos-only statistics. These only apply to a service with unconstrained delegation. The CIFS client presents a Ticket-Granting Ticket (TGT) to the unconstrained CIFS service, which then uses that TGT to get a Service Ticket for a back-end filer. These fields count the number of cross-forest TGTs that the ARX requested. A cross-forest TGT grants access from one forest to another. Use [show active-directory](#) to view all realms (or Windows domains), all forests, their connections to one another, and the Domain Controller(s) for each.

Service tickets granted, and

Service tickets denied are Kerberos-only statistics that apply to both constrained and unconstrained delegation. These are the results from attempting to attain Service Tickets on behalf of clients.

Control plane expired TGTs count the problems that the control plane has encountered with TGTs.

Fast path expired TGTs are TGT errors for NSM-only transactions.

Errors contacting Secure Agent may indicate a connection problem with the Secure Agent's DC host. These counters only apply to a CIFS service that uses unconstrained delegation (or is not joined to its domain). This is an NTLM/NTLMv2 counter. Use [show ntlm-auth-server](#) to show the host(s) for the Secure Agent, and use [show exports host dc-ip-address connectivity](#) to check connectivity to the DC.

SMB signing incompatibility counts the number of times that a filer and the namespace behind the CIFS service could not successfully negotiate SMB signing. In this case, one end of the connection requires SMB signing and the other end of the connection refuses it. You can use the [cifs filer-signatures](#) command to set the SMB signing policy for a namespace.

S4U-to-self tickets granted and

S4U-to-self tickets denied count the successful and failed attempts for the CIFS service to get a service ticket for itself. These only apply to a CIFS service configured for constrained delegation. Such a CIFS service needs a service ticket to itself for each of its Kerberos clients. A constrained CIFS service uses the Kerberos Service-for-User (S4U) protocol extension, which necessitates this ticket. This is the total number of such tickets that have been denied, including the cross-realm tickets shown in the **Cross-Realm TGTs denied** field above. If these S4U tickets are denied, verify that the CIFS service still has an account configuration at a local DC, and that the account's password key has not expired. If the password key has expired, you must use [domain-join](#) to rejoin the CIFS service to its domain.

Guidelines: Verbose Output

If you use the `verbose` keyword, additional tables appear to display CIFS-authentication failures. The tables display detailed reasons for the last 20 failures.

The Client Authentication section has a table entitled **Authentication Failure Reason Table**. Each failure appears on two lines with the following fields:

Error Code is an internal code name for the error (for example, `KRB5KRB_AP_ERR_MODIFIED`).

Error Description is the text for the error (for example, "Message stream modified").

Count is the number of times the error has occurred. Only unique errors appear in this table; this counter increments each time the CIFS service gets each error.

Last Time is the date and time the error was last received.

Last Client IP is the IP address of the client to get the error.

The Filer Authentication section has a similar table. Instead of showing a filer IP in all cases, this attempts to show the **Principal** involved with each back-end authentication error.

These tables contain up to 20 unique authentication errors. After a service reaches 20 errors, any new errors are dropped until you clear the statistics. The `clear statistics cifs authentication` command clears all CIFS-authentication statistics, including these tables.

Sample

```
bstnA(cfg)# show statistics cifs authentication ac1.medarch.org
shows CIFS-authentication statistics for the CIFS service at "ac1.medarch.org."
See Figure 41.19 on page 41-46 for sample output.

show statistics cifs fastpath

Purpose Use the `show statistics cifs fastpath` command to show counters and statistics for CIFS servers. The NSM processors keep these statistics.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics cifs fastpath [all | slot.processor]`

all (optional) shows statistics from all NSM processors.

slot.processor (optional: 2.1-12 on ARX-4000; 1.2-5 on ARX-2000; 1.2 on ARX-500 or ARX-VE) focuses on the statistics for one NSM slot and processor. If you omit this, the output contains statistics from all NSM processors; the effect is the same as using the **all** keyword.

Guidelines The output is a table with one row per NSM processor. Each row contains the following fields:

Proc identifies the NSM processor. This is in *slot.processor* format.

Transactions Handled is the sum of front-end and back-end CIFS transactions handled by the processor since the last reboot.

FrontEnd Connections shows the current number of connections from clients.

BackEnd Connections is the current number of connections made to filers on behalf of CIFS clients.

File Info shows the current number of files, pipes, and directories held open on this processor.

File Handles is the total file handles associated with the above files, directories, and/or pipes. This number may be lower than the above number because multiple clients may be accessing the same files.

Samples `bstnA(cfg)# show statistics cifs fastpath`
shows CIFS statistics for all CIFS services. See [Figure 41.20](#) for sample output.

`bstnA(cfg)# show statistics cifs fastpath 2.4`
focuses on a single NSM processor. See [Figure 41.21](#) for sample output.

show statistics cifs path-cache

Purpose Each NSM processor can keep a cache of file/directory paths to improve CIFS performance. Use the `show statistics cifs path-cache` command to show counters and statistics for this cache.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics cifs path-cache namespace [volume [slot.processor]]`

namespace (1-30 characters) is the name of a namespace. Use the [show namespace](#) command for a list of all namespaces.

volume (optional, 1-1024 characters) focuses on the path cache for a single volume. The [show global-config namespace ns-name](#) command lists all volumes (and other parameters) in a particular namespace.

slot.processor (optional: for example, 2.4) focuses on a single NSM processor's cache.

Guidelines Use the [cifs path-cache](#) command to enable the CIFS path-cache for a volume.

The output is one or more tables, where each table contains statistics for each volume on each NSM processor. Each NSM processor keeps a separate cache for every managed volume it serves. The header for each table identifies its managed volume and its NSM processor (in *slot.processor* format). The table body contains the following counters:

Total Hits is the number of path queries from CIFS clients where the path was found in the cache.

Total Misses counts the path queries where the answer was not in the cache. These result in a "lookup" query to the namespace software; the path goes into the cache (for future requests) after a successful lookup.

DNAS Lookup Fails shows the number of path lookups that failed. (The namespace software is called *DNAS*.) A lookup can fail when a file or directory's path is in flux due to migrations, filer error, or some other issue. Many of these issues are counted in the fields below.

The next block of fields show the number of path-cache entries that have been declared "invalid," and removed from the cache.

DNAS Invalidates shows the number of paths that were removed from the cache due to an "invalidate" message from the namespace software. The namespace software sends an "invalidate" message when a file or directory's path is changing: during a migration (caused by rules like [place-rule](#), and [auto-migrate](#)), during a directory rename, while a managed-volume share is being removed (caused by, for example, [remove-share migrate](#)), while the volume is being disabled (no [enable \(gbl-ns, gbl-ns-vol\)](#)), or during a share import ([enable \(gbl-ns-vol-shr\)](#)).

Client Invalidates is the number of paths that have been invalidated (removed from the cache) due to some client action, such as a rename or delete.

Guidelines (Cont.)

Filer Reply Invalidates is the number of paths that have been invalidated by a filer's unexpected "not found" response. This is typically a case where a filer application, such as anti-virus software, has moved a file. If the volume has [auto sync files](#) enabled, it responds to this by probing the filer and updating its metadata with the correct path.

Age Invalidates counts the number of paths that were removed from the cache due to a 120-second timeout. Each path stays in the cache for at least 120 seconds before being removed, to avoid wasting valuable memory. The clock restarts every time a client requests the path.

Insert Invalidates shows the number of paths that were removed from the cache to make room for a new path. This only occurs when the path cache exceeds its maximum size; the NSM processor removes the oldest entries first.

Mgmt Invalidates counts the paths that were invalidated due to a CLI or GUI command that destages a volume ([nsck ... destage](#)) or rebuilds it ([nsck ... rebuild](#)). This invalidates all paths in the volume.

Coll Invalidates is the number of paths that were declared invalid when a case collision was discovered. A case collision is a path on another share that is exactly the same except in letter case (for example, "/myDir/yourDir/yourFile.doc" has a case collision with "/myDir/yourDir/YOURFILE.DOC").

The final block of fields summarizes the path-cache statistics:

Current Entries shows the number of paths in the cache now.

Max Entries shows the maximum size of the cache since the last reboot.

Total Entries is the sum of all path-cache entries since the last reboot.

Use the [clear statistics cifs path-cache](#) command to clear the above statistics.

To see the current contents of the path cache, use the [show cifs-service path-cache](#) command.

Samples

```
bstnA(cfg)# show statistics cifs path-cache insur
```

shows path-cache statistics for the "insur" namespace. See [Figure 41.22](#) for sample output.

```
bstnA(cfg)# show statistics cifs path-cache medarcv /rcrds
```

focuses on a single volume. See [Figure 41.23 on page 41-52](#) for sample output.

```
bstnA(cfg)# show statistics cifs path-cache medarcv /rcrds 2.6
```

focuses on a single volume and processor. See [Figure 41.24 on page 41-53](#) for sample output.

show statistics cifs symlinks

Purpose In a multi-protocol (CIFS and NFS) volume, CIFS clients can follow the symbolic links (or symlinks) created by NFS clients. Use the `show statistics cifs symlinks` command to show counters and statistics for symlink usage by CIFS clients.

Mode (any)

Security Role(s) network-technician, network-engineer, storage-engineer, backup-operator or crypto-officer

Syntax `show statistics cifs symlinks [volume-group id]`

volume-group id (optional) narrows the scope to a single volume group. A *volume group* is a failure domain for a group of volumes in the same namespace. If you omit this option, the output shows statistics for all of the volumes on the system.

Guidelines Multi-protocol volumes keep these statistics for de referencing symlinks for its CIFS clients.

To disable all CIFS access to symlinks in a given volume, you can use the `cifs deny-symlinks` command.

You can use the `clear statistics cifs symlinks` command to clear these statistics. The statistics also clear after every chassis reboot.

Guidelines: Output The output is a group of tables, one per volume group. Each table contains the following statistics:

Symlink requests dereferenced from backend is the number of symlink reads that required a query to the back-end filer. These are symlinks requested by CIFS clients. The volume software queries the back-end filer once and then caches the symlink target for future CIFS-client access.

Symlink requests dereferenced from cache counts the symlinks that were accessed from the internal cache, without requiring any back-end access.

Total symlink requests dereferenced is the sum of the above two counters. This is the total number of times that CIFS clients accessed symlinks in the given volume group.

Entries in symlink cache shows the current number of symlinks stored in the internal cache. These are symlinks accessed by one or more CIFS clients in the past 2 minutes.

Symlink cache size indicates the amount of memory currently used by the internal symlink cache. This is rounded to the nearest Kilobyte.

Cache hit rate is the percentage of symlinks resolved by accessing the internal cache. The remaining symlinks were resolved by querying a back-end filer.

Guidelines: Output (Cont.) The remaining statistics count all failed attempts to de reference symlinks for CIFS clients:

Failed symlink requests dereferenced to a dangling path counts all attempts to access a dangling symlink. A *dangling* symlink is one that points to a non-existent file or directory.

Failed symlink requests dereferenced to an absolute path is the number of attempts to access an absolute symlink. An *absolute* symlink is one starts with a slash (/) or back slash (\); for example, “/vol/vol3/flightRecords/2009.” A CIFS-client machine invariably has a different root path than the one in the symlink (such as “e:\flightRecords\2009”), so it cannot possibly interpret an absolute symlink.

Failed symlink requests due to filer timeout is the number of back-end queries that failed due to a back-end-filer timeout.

Failed symlink requests due to other filer error counts the back-end queries that failed due to any non-timeout error by the filer.

Samples bstnA(cfg)# **show statistics cifs symlinks**
shows CIFS symlink statistics for all volume groups on the ARX. See [Figure 41.25](#) for sample output.

bstnA(cfg)# **show statistics cifs symlinks volume-group 4**
focuses on a single volume group. See [Figure 41.26 on page 41-56](#) for sample output.

Related Commands [clear statistics cifs symlinks](#)

show statistics cifs work-queues

Purpose A CIFS volume uses internal work queues to manage its CIFS-related tasks. There is a main work queue for the bulk of client requests, an authentication queue for client-authentication tasks, two queues for communication with the data plane (networking software), and so on. The `show statistics cifs work-queues` command shows the time that CIFS work items have spent waiting in these work queues, as well as the time used to perform the actual work. You can use this information for troubleshooting CIFS performance issues.

Mode (any)

Security Role(s) network-technician, network-engineer, storage-engineer, crypto-officer, or operator

Syntax `show statistics cifs work-queues volume-group vg-id`
`show statistics cifs work-queues instance instance-id`

volume-group *vg-id* (optional, 1-255) chooses a volume group. A *volume group* is a failure domain for a group of volumes in the same namespace. You can use [show volume-group](#) for a list of all volume groups on the system, and to see which volumes are assigned to each volume group.

instance *instance-id* (optional) chooses a namespace by its instance ID. Instance IDs often appear in syslog messages, which you can view with [show logs syslog](#). You can also see instance IDs with [show namespace all](#), which shows full details on all namespaces in the system.

Guidelines The [clear statistics cifs work-queues](#) command clears most of these statistics, and [clear statistics filer](#) clears the rest of them. A chassis reboot clears all of them at once.

There are some related CLI commands that can aid in troubleshooting CIFS connections. Use [show cifs-service user-sessions](#) to see the which CIFS clients are currently connected to the ARX. Use [show cifs-service client-activity](#) to see how many back-end session, tree connections, and files they currently have open. The [show cifs-service open-files](#) command shows details about currently-open files. For details about currently-held Kerberos tickets, use the [show cifs-service kerberos-tickets](#) command. The [show statistics domain-controller](#) command examines the NTLM-related communication with domain controllers in the network.

Guidelines: Output The output is a series of tables. The work queues only function in managed volumes that support CIFS. The tables are empty for a volume group or namespace that only supports NFS-only volumes and/or [direct](#) volumes.

**Guidelines: CIFS
Work Queue
Histograms**

CIFS work queue pool statistics shows the usage statistics for each CIFS work queue in the chosen volume group or namespace instance.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone issues the [clear statistics cifs work-queues](#) command or reboots the chassis.

Under the **Reset** line, a separate sub table appears for each work queue:

- **Work list...** shows the name and purpose of the current work queue.
- ***n* items active or waiting...** displays the number of work items currently in the queue, along with the highest number ever in the queue at one time. The time stamp is for the most-recent time when the queue had its highest number of work items.
- ***x* items completed, *y* discarded** is the number of completed and discarded items processed in this work queue. A completed item may have succeeded or failed. Items are discarded from the queue only when system resources are low and traffic is high, and the system only discards items that have waited a long time. A discard occurs before any thread begins executing the work item.
- **Average...** shows the average time that completed items spent waiting in the queue, and the average time that the volume software spent processing the work items after they were taken off of the queue. The times are measured in microseconds; there are 1,000,000 microseconds in 1 second.
- **Time waiting in queue** is a histogram showing various time amounts (0.001 second, 0.01 second, 0.1 second, and so on) and the number of work queue items that waited in the queue for that amount of time. The smallest time period is 0.001 seconds, which is 1 millisecond or 1,000 microseconds. This histogram only appears if at least one work item was in the queue since the last Reset time.
- **Time processing on thread** is a similar histogram, showing the time that threads spent processing the work-queue items after having taken them off the queue.

Work-queue status messages, if any, appear after all of the work-queue tables. Each of these is a declaration that a work item was excessively “slow,” was slow long enough to be declared “stuck,” or eventually got “done” after being slow or stuck. Each event appears in its own row with the event type (SLOW, STUCK, or DONE), a time stamp for when the work item reached this state, the name of the work queue, the time spent working on the item, the name of the CIFS command sent to the data plane, and any other relevant information about the work item.

Guidelines:
Processing-Time
Table

Average processing time per operation type is a table of Server Message Blocks (SMBs, also known as CIFS Commands) processed through the above queues. These are commands that originate from ARX clients. You can use this table to determine if some client requests take longer than others.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone issues the [clear statistics cifs work-queues](#) command or reboots the chassis.

Under the **Reset** line, a table of SMBs appears. These are all the SMBs processed by the work queues since the Reset time. Each SMB appears in its own row with the following columns:

- **CIFS SMB** is the name of the SMB,
- **Count** is the number of these SMBs received from clients,
- **Avg time (uSec)** is the average number of microseconds (millionths of a second) required to fully process the request. This is the time in the work queue plus the time for the thread to process the work item.

All SMBs shows the total count for all of the above SMBs, and the average time to process them.

Guidelines: Filer-RTT
Table

Average file server round-trip time per operation type is another table of SMBs forwarded to back-end filers and servers. This table helps to determine if a filer or server is slow.

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone issues the [clear statistics filer](#) command or reboots the chassis. This is a different **clear** command than the one used for the other statistics.

Under the **Reset** line, a table of SMBs appears. These are all the SMBs sent to the filers since the Reset time. Each SMB appears in its own row with the following columns:

- **CIFS SMB** is the name of the SMB,
- **Count** is the number of these SMBs sent to filers,
- **RTT (uSec)** is the average round-trip time (RTT) to and from the filer.

All SMBs shows the total count for all of the above SMBs, and the overall average RTT for them.

The next two rows show the total Response Timeouts and Network Errors, if any.

Guidelines:
Authentication Table

Time spent in authentication shows the time spent with CIFS-client authentication. (For counters of various authentication tasks, you can use the [show statistics cifs authentication](#) command.)

Reset... shows the last time these statistics were cleared. The software resets these statistics whenever someone issues the [clear statistics cifs work-queues](#) command or reboots the chassis.

Under the **Reset** line, a separate sub table appears for each authentication type: Kerberos, Netlogon (NTLM/NTLMv2 for CIFS services that use constrained delegation (see [domain-join](#))), or ARX Secure Agent (NTLM/NTLMv2 for CIFS services that use unconstrained delegation or no delegation).

Kerberos service ticket requests focuses on Kerberos authentications.

- **Total calls** is the number of Kerberos tickets requested from the ARX-CIFS service.
- **Elapsed time in call** is a histogram showing various time amounts (0.001 second, 0.01 second, 0.1 second, and so on) and the number of service-ticket requests that took that amount of time. The smallest time period is 0.001 seconds, which is 1 millisecond or 1,000 microseconds. This histogram does not appear unless at least one client authenticated with Kerberos.
- **Average time** is the average time for all service-ticket requests.

Netlogon requests shows the time taken for NTLM and NTLMv2 requests through Netlogon. These occur for a front-end CIFS service that uses constrained delegation. You choose the delegation type when you run [domain-join](#) for the CIFS service.

- **Total calls** is the number of Netlogon requests received by the ARX-CIFS service.
- **Elapsed time in call** is a histogram showing various time amounts (0.001 second, 0.01 second, 0.1 second, and so on) and the number of Netlogon requests that took that amount of time. The smallest time period is 0.001 seconds, which is 1 millisecond or 1,000 microseconds. This histogram does not appear unless at least one client authenticated with NTLM or NTLMv2 through a CIFS service with constrained delegation.
- **Average time** is the average time for all Netlogon requests.

ARX Secure Agent requests shows the time taken for NTLM and NTLMv2 requests through the ARX Secure Agent (see [ntlm-auth-server \(gbl-ns\)](#)). These occur for a front-end CIFS service that uses unconstrained delegation or no delegation. You choose a delegation type when you run [domain-join](#) for the CIFS service.

- **Total calls** is the number of NTLM and NTLMv2 requests received by the unconstrained ARX-CIFS service.
- **Elapsed time in call** is a histogram showing various time amounts (0.001 second, 0.01 second, 0.1 second, and so on) and the number of NTLM + NTLMv2 requests that took that amount of time. The smallest time period is 0.001 seconds, which is 1 millisecond or 1,000 microseconds. This histogram does not appear unless at least one client authenticated with NTLM or NTLMv2 through a CIFS service with unconstrained delegation.
- **Average time** is the average time for all NTLM and NTLMv2 requests.

Guidelines:
Authentication Table
(Cont.)

Table of longest recorded round-trip times shows up to 20 clients who took the longest time for authentication. Each authentication session appears in one row of the table, with the following fields:

- Timestamp is the time that the client started the authentication process.
- Type is NL (Netlogon request), KRB (Kerberos ticket request), or ASA (ARX Secure Agent request).
- Time (uSec) is the time consumed by the authentication request, in microseconds.
- Principal Name identifies the CIFS client that invoked the authentication request. You can use `show cifs-service user-sessions` to see the clients that are currently connected to the ARX.

Sample

`bstnA(cfg)# show statistics cifs work-queues volume-group 2`
shows the work-queue statistics for volume group 2. See [Figure 41.27 on page 41-62](#) for sample output.

show statistics domain-controller

Purpose Use the `show statistics domain-controller` command to view NTLM-usage statistics for a particular domain controller (DC).

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics domain-controller ip-address`

ip-address identifies a DC .

Guidelines This command shows the statistics for communication with a particular DC. The statistics are divided into two categories: statistics for NTLM Netlogon authentications and statistics for LDAP pings.

The NETLOGON statistics only apply to CIFS services that use *constrained delegation*, which is chosen when [domain-join](#) is performed for the service. If you use unconstrained delegation for your service, but still support NTLM or NTLMv2 for the service's clients, use the [show ntlm-auth-server](#) command to find NTLM-authentication statistics. The LDAP-ping statistics in this command apply to any CIFS service, whether or not it uses constrained delegation.

This command shows all the counters for this NTLM-related communication with a particular DC. You can use the [clear statistics domain-controller](#) command to clear these statistics. The statistics also clear after every chassis reboot.

Guidelines: Output The output is divided into two tables: NTLM NETLOGON Authentication Statistics and LDAP Ping Statistics.

Guidelines: Netlogon Authentication Statistics The NTLM NETLOGON Authentication Statistics table only applies to CIFS services that use constrained delegation, as explained above. The CIFS services that can use this DC are any that are in its Windows domain.

An ARX CIFS service uses Netlogon service for NTLM and NTLMv2 authentication. Through the Netlogon protocol, each CIFS service sets up a secure channel with the DC. For each client that authenticates to the CIFS service with NTLM or NTLMv2, the service sends a client's username and password through that encrypted channel. If the password is correct, the DC returns the domain security identifiers (SIDs) and access rights for the user back through the secure channel.

Domain Controller IP is the IP address you entered in the command.

Last Reset *time* shows the last time these counters were cleared, either with a chassis reboot or with the [clear statistics domain-controller](#) command. All of the counters below started at this time.

Successful NTLM and

Successful NTLMv2 count the number of successful NTLM authentications at the selected DC.

Guidelines: Netlogon Authentication Statistics (Cont.)

Failed NTLM is a total number of NTLM failures at the DC. The counters below show the specific failures.

- **No Such User** counts the clients who used an unidentified username for the Windows domain.
- **Bad Password** is the number of failures due to an incorrect password for a valid username.
- **Account Disabled** shows the number of failures due to an administratively-disabled user account.
- **No logon server** counts the number of failures due to a service interruption. Each time, the ARX service was unable to reach the DC's Netlogon server. You can use [show active-directory status](#) to check the status of the DC connection, and you can set a preference for another DC in the same Windows Domain with [forest-root ... preferred](#), [child-domain ... preferred](#), or [tree-domain ... preferred](#).
- **Ntlm Blocked** is the number of times the DC blocked NTLM access. This can be controlled at the DC with **Local Security Policy**; the specific Local Policy settings are "Network Security:Restrict NTLM:*policy-name*."
- **Other** shows the number of failed authentications outside any of the above categories.

Failed NTLMv2 is a total number of NTLMv2 failures at the DC. The counters below this summary field break down the specific failures, as described above.

Schannel Inits are the number of times that the Secure Channel between the CIFS service and the DC has been re-initialized.

Avg Request SRT (mSec),

Min Request SRT (mSec), and

Max Request SRT (mSec) show the average, minimum, and maximum round-trip times for NTLM authentications. This measures the elapsed time the Netlogon agent uses to process an authentication request. This is the processing time within the agent itself plus the communication time between the agent and the DC. The times are measured in milliseconds (there are 1,000 milliseconds in one second).

Avg DC SRT (mSec),

Min DC SRT (mSec), and

Max DC SRT (mSec) show the average, minimum, and maximum round-trip times for NTLM authentications to this DC. This measures the round trips between the internal Netlogon Agent and the DC. These times are also measured in milliseconds.

Guidelines: LDAP Ping Statistics The LDAP Ping Statistics table shows the results of periodic pings to the DC. The pings measure the ability to reach the DC as well as the latency of the DC connection:

Each ping-statistics table contains the following information:

Last Reset (Local Time) *time* shows the last time these counters were cleared with [clear statistics domain-controller](#) or a chassis reboot. All of the counters below started at this time.

Total Count is the number of LDAP pings to the DC.

Success Count and

Error Count show the numbers of successful and failed pings.

Average RTT (uSec) is the average round-trip time for LDAP pings. This is measured in microseconds. There are 1,000,000 microseconds in one second.

RTT Histogram is a sub-table to display the numbers of pings in certain time ranges. Each row defines a time range in microseconds: 0 to 1000 microseconds, 1000 to 2000 microseconds, and so on. At the end of each row is the number of LDAP pings whose round-trip times where in this range.

Sample `bstnA(cfg)# show statistics domain-controller 192.168.25.102`
shows NTLM statistics for the DC at 192.168.25.102. See [Figure 41.28](#) for sample output.

show statistics domain-controller load-balancing

Purpose Whenever a Windows domain is served by multiple domain controllers (DCs), the ARX rotates its queries between the “active” DCs in that group. Use the `show statistics domain-controller load-balancing` command to view the statistics for using these DCs. You can use this output to assess the usage of one DC over another.

Mode (any)

Security Role(s) crypto-officer, storage-engineer, network-engineer, network-technician, or operator

Syntax `show statistics domain-controller load-balancing`

Guidelines This command shows the statistics for communication with your DCs. You can use this output to compare the number of Kerberos requests to each DC. The output contains one table for every Windows Domain in the Active Directory. (You can use the [active-directory update seed-domain](#) command to discover all of the domains and DCs in the current Active Directory.) Each table contains one row per DC in that domain, with the following columns:

DC IP Address identifies the DC.

Kerberos Requests is the number of Kerberos requests sent to the DC since the last reboot, or since someone cleared the statistics with [clear statistics domain-controller load-balancing](#).

Preferred is either Yes or No. The ARX always directs its Kerberos requests to a preferred DC if any are reachable. DCs at the same AD site as the ARX are preferred by default. You can also use the [child-domain](#), [forest-root](#), or [tree-domain](#) command to manually set a DC preference.

These statistics all restart at 0 (zero) after the ARX reboots. You can manually reset these statistics with the [clear statistics domain-controller load-balancing](#) command.

Sample `bstnA(cfg)# show statistics domain-controller load-balancing`
shows Kerberos-usage statistics for all DCs behind the “bstnA” ARX. See [Figure 41.29](#) for sample output.

show subshare-cache

Purpose A managed volume that supports [filer-subshares](#) keeps all of its subshare information in cache memory. This decreases the number of RPC calls between the ARX and its back-end filers during `sync subshare` operations. You can use this command to show the current contents of this cache.

Mode priv-exec

Security Role(s) network-technician, network-engineer, storage-engineer or crypto-officer

Syntax `show subshare-cache [filer ext-filer-name] [report prefix]`

filer *ext-filer-name* (optional, 1-64 characters) focuses on a particular external filer. This is the name of the filer in the ARX configuration. For a list of configured external filers, use [show external-filer](#).

report *prefix* (optional, 1-64 characters) sends the subshare-cache output to a report instead of the screen. The CLI displays the full report name after you enter the command. The report is named as follows:

prefix_yyyymmddHHMM.rpt, where *prefix* is chosen here and the rest of the filename is the current date and time.

Default(s) None

Guidelines A *filer subshare* is any CIFS share that is inside an imported CIFS share. A client who connects to a front-end subshare, if the subshares are configured as described in the [filer-subshares](#) documentation, is passed through the managed volume directly to a corresponding subshare on a back-end filer. The filer can then enforce its subshare ACL, as opposed to the top-level ACL of the imported share. Each front-end subshare (visible to your CIFS clients) maps to one or more back-end subshares. The state of every filer share (and share ACL) resides in a memory cache. You can use this command to show the cache, or the cache for one filer.

You have the option to clear this cache for a filer where the ACLs and/or shares have changed since import. Use the [clear subshare-cache](#) command to clear the subshare cache.

Guidelines: Output The output is a series of nested tables, one per back-end filer. Each filer has a table with the following heading:

Subshare cache for filer *ip-address*

Each filer table contains a separate table for each of its imported shares:

Subshares nested below import share bulkstorage on filer *ip-address* is the heading for the first table. Each share contains its own sub table, with several fields to describe the share:

- **Share** is the name of the share in “\ip-address\share-name” format. CIFS clients can use this path to access the storage.
- **Path** is the file-system path on the filer itself, including the drive letter. If you log into the filer, you can use this path to directly access the storage.
- **Import** is the name of the import share, the one that was imported into a managed volume. This is typically the container share for the current subshare. This says “[This is the imported share.]” for each top-level share.
- **RelPath** only appears for a subshare. This is the relative path to the subshare, starting from the root of the imported share.
- **ACL** is the Access Control List (ACL) for this share or subshare. This must match the ACL on all matching subshares. (A matching subshare is a subshare at the same relative path of another import share.)

After all imported shares and subshares, each filer is re-iterated to show all of its unimported shares (called *orphan* shares):

Orphan (unnested) share caches for filer *ip-address* is the heading for the second filer table. These are shares outside the imported share(s). Each of these shares contains a similar sub table with these fields:

- **Share** and.
- **Path** are described above.
- **Remark** only appears for special default shares. This is a note about a share, such as “Default share” for the root share on a disk drive or “Remote Admin” for the special ADMIN\$ share.
- **ACL** is also described above.

Sample bstnA# **show subshare-cache**
shows the full subshare-cache. See [Figure 41.30 on page 41-75](#) for sample output.

```
bstnA# show subshare-cache filer fs2 report fs2_sbshrs
```

```
Creating subshare-cache report: fs2_sbshrs_201004290537.rpt
```

shows the subshare-cache for the external filer named “fs2,” and sends it to a report.

ARX Manager (GUI) Maintenance

This chapter contains reference information for maintaining the ARX GUI, also known as the ARX Manager interface.

cipher

Purpose This command is designed for use with a running-config script only. As part of running-config playback, this command re-establishes ciphers used when the ARX Manager (the GUI) performs SSL negotiation.

Mode cfg-ssl

Security Role(s) crypto-officer or network-engineer

Syntax `cipher {all | defaults | cipher-name}`

all chooses all of the ciphers

defaults chooses the default (strongest) ciphers only.

cipher-name identifies one cipher to use in SSL negotiation. Type ? for a full list of available ciphers. The running-config script invokes this command multiple times, once for each cipher.

Default(s) half of the ciphers (the strongest) are used by default

Guidelines This command is not intended for ARX administrators.

The [ssl](#) command leads to the cfg-ssl mode with this command and one other. The output of [show running-config](#) includes both of these commands so that the GUI is properly certified after re-playing the running-config script.

Related Commands [ssl](#)
[show running-config](#)

gui

Purpose The `gui restart` command shuts down and restarts the ARX Manager, the Graphical User Interface (GUI) for the ARX.

You can use the `no gui` command to shut down the ARX GUI without immediately restarting it. The `gui` command starts the GUI after it was previously shut down.

Mode `priv-exec`

Security Role(s) `crypto-officer` or `network-engineer`

Syntax `gui [restart]`
`no gui`

`restart` (optional) stops and restarts the GUI with a single command.

Default(s) `gui`

Guidelines The GUI runs automatically when [management access](#) (along with its sub command, [authentication](#)) is set up for HTTP or HTTPS. You can use `no gui` to shut down the GUI, or `gui restart` to stop and restart it.

Samples `bstnA# no gui`
shuts down the GUI for the current ARX.

`bstnA# gui restart`
stops and restarts the GUI.

Related Commands [management access](#)
[authentication](#)

ssl

Purpose	This command is designed for use with a running-config script only. As part of running-config playback, this command re-establishes the SSL certificate for the ARX Manager (that is, the GUI).
Mode	cfg
Security Role(s)	crypto-officer or network-engineer
Syntax	ssl
Default(s)	None
Guidelines	<p>This command is not intended for ARX administrators.</p> <p>The <code>ssl</code> command leads to a submode with commands for entering an encrypted SSL certificate and choosing the ciphers for SSL negotiation. The output of show running-config includes these commands so that the GUI is properly certified after re-playing the running-config script.</p>
Related Commands	show running-config

ssl-key-store

Purpose This command is designed for use with a running-config script only. As part of running-config playback, this command re-establishes the SSL certificate for the ARX Manager (or GUI).

Mode cfg-ssl

Security Role(s) crypto-officer or network-engineer

Syntax `ssl-key-store key-data`

key-data (1-2048 characters) is one part of the encrypted SSL certificate. If the encrypted data exceeds 2048 characters, the running-config script invokes this command again with the next segment of the string.

Default(s) None

Guidelines This command is not intended for ARX administrators.
The `ssl` command leads to the cfg-ssl mode with this command and one other. The output of `show running-config` includes both of these commands so that the GUI is properly certified after re-playing the running-config script.

Related Commands `ssl`
`show running-config`
